8:00AM P29.00001 Prospects for a prototype quantum processor based on three-dimensional superconducting cavities and qubits, CHAD RIGETTI, IBM T. J. Watson Research Center — Superconducting qubits embedded in three-dimensional waveguide resonators (recently pioneered by Paik, et al., arXiv:1105.4652) have shown excellent coherence properties and an ease of implementation that make them an enticing core component for small prototype quantum processors. The relatively large physical dimensions of the microwave modes of these 3D-cQED systems may lead one to discount their prospects for scaling. We argue that the larger characteristic dimensions, among others factors, in fact facilitate scaling for currently practicable prototype systems of ~ 10 to 1,000 qubits. This emerges from significantly reduced fabrication complexity and costs, larger tolerances to parameter deviations, a more prevalent role for off-the-shelf components, and greater amenability to full-device electromagnetic simulation. At IBM we are working towards a modular quantum processor prototype based on 3D-cQED. Multi-qubit cavities, each implementing an artificial NMR molecule, are to be connected in an array by non-linear elements which double as tunable couplers between qubits in adjacent cavities and as single-shot readout circuitry. The resulting lattice of physical qubits provides a fabric on which surface code error correction can take place, implying a fault-tolerant threshold error rate for this architecture of $\sim 1\%$. We describe recent experiments demonstrating a two-qubit gate with a two qubit/one cavity device and progress toward tunable coupling of qubits in adjacent cavities.

8:36AM P29.00002 Prime factoring using a Josephson phase-qubit architecture: $15 = 3 * 5$, ERIK LUCERO, R. BARENDs, J. BOCHMANN, Y. CHEN, B. CHIARO, J. KELLY, M. LENANDER, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, P. ROUSHAN, D. SANK, A. VAINSENER, University of California, Santa Barbara, H. WANG, Zhejiang University, J. WENNER, T. WHITE, Y. YIN, A.N. CLELAND, JOHN M. MARTINIS, University of California, Santa Barbara — We demonstrate a compiled version of Shor's algorithm using a quantum processor. The processor consists of "off-the-shelf" components: qubits and resonators arranged in the ReZQu architecture. We have performed the algorithm for $N=15$ and the period $r=2$. The required two and three qubit entanglement is observed during the computation, which exemplifies the quantum nature of the algorithm.

8:48AM P29.00003 Building Transmon Qubits in the ReZQu Architecture, JULIAN KELLY, R. BARENDs, J. BOCHMANN, B. CHIARO, Y. CHEN, M. LENANDER, E. LUCERO, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, P. ROUSHAN, D. SANK, A. VAINSENER, J. WENNER, T. WHITE, Y. YIN, ANDREW CLELAND, JOHN M. MARTINIS, UC Santa Barbara — Transmon qubits are promising candidates for use in a superconducting quantum computer because of their long coherence times, but traditionally involve a difficult measurement scheme. By reading out each transmon through a phase qubit, we are able to take advantage of the single shot and multiplexed readout technologies already in use. This allows us to drop transmons into the ReZQu architecture. However, fabricating a transmon and phase qubit on the same chip comes with its own set of challenges. We present fabrication techniques and preliminary data as we move toward our next generation of qubits.

9:00AM P29.00004 High-fidelity CZ gate for the quantum Von Neumann architecture¹, JOYDIP GHOSH, University of Georgia, Athens, ANDREI GALIAUTDINOV, ALEXANDER KOROTKOV, University of California, Riverside, ZHONGYUAN ZHOU, MICHAEL GELLER, University of Georgia, Athens, JOHN MARTINIS, University of California, Santa Barbara — The building block of a scalable superconducting quantum computer has recently been demonstrated [M. Mariantoni et al., Science 334, 61 (2011)]. This architecture consists of superconducting phase qubits capacitively coupled both to individual memory resonators as well as a common bus. In this work we investigate the fidelity of a CZ logic gate between a qubit and bus in a multi-qubit device. Our results show that it is possible to implement the CZ gate with 99.99% intrinsic fidelity in 30ns with a simple two-parameter pulse profile (plus two Z rotations). An analytical error model is also developed to explain and extend this result.

¹IARPA

9:12AM P29.00005 High-fidelity gates towards a scalable superconducting quantum processor, JERRY M. CHOW, ANTONIO D. CORCOLES, JAY M. GAMBETTA, CHAD RIGETTI, IBM TJ Watson Research Center, BLAKE R. JOHNSON, BBN Raytheon Technologies, JOHN A. SMOLIN, SETH MERKEL, STEFANO POLETO, JIM ROZEN, MARY BETH ROTHWELL, GEORGE A. KEEFE, MARK B. KETCHEN, MATTHIAS STEFFEN, IBM TJ Watson Research Center — We experimentally explore the implementation of high-fidelity gates on multiple superconducting qubits coupled to multiple resonators. Having demonstrated all-microwave single and two qubit gates with fidelities $> 90\%$ on multi-qubit single-resonator systems, we expand the application to qubits across two resonators and investigate qubit coupling in this circuit. The coupled qubit-resonators are building blocks towards two-dimensional lattice networks for the application of surface code quantum error correction algorithms.

9:24AM P29.00006 Driving two-qubit entanglement with an enhanced ZZ interaction in circuit QED¹, BLAKE R. JOHNSON, C.A. RYAN, M.P. DA SILVA, Raytheon BBN Technologies, J.M. CHOW, J.M. GAMBETTA, S. MERKEL, IBM T.J. Watson Research, T. OHKI, Raytheon BBN Technologies — The quantum bus architecture is fast becoming a popular approach for coupling superconducting qubits [1,2]. With two fixed-frequency qubits coupled by a resonator, it is possible to engineer the system's frequencies such that the qubits experience a strong ZZ interaction. This interaction can be used as a resource for creating entanglement when needed, but can also be suppressed at will using appropriate decoupling sequences. We will show measurements of a device where this ZZ interaction is enhanced by interactions with higher-levels of superconducting transmon qubits. To achieve high-fidelity control in this regime, we employ robust composite pulses and optimal control methods to decouple the two-qubit interaction during single-qubit operations. The resulting system serves as a testbed for adapting control techniques from liquid-state NMR to fixed-frequency superconducting qubits.

9:36AM P29.00007 Controlling superconducting qubits in the presence of a strong, constant ZZ interaction, SETH MERKEL, IBM, IBM QUANTUM COMPUTING TEAM — We look at the problem of optimal gate design in a system of two superconducting qubits coupled by a cavity. The system is designed to have a strong "always on" ZZ interaction, which is essential for two-qubit entangling gates, but presents a challenge for single qubit manipulation. Using pulse shaping ideas from NMR we are able to analytically derive single qubit gates that remove this unwanted coupling to 3rd order in the Magnus expansion, and applying DRAG corrections prevents leakage to higher oscillator levels. In the limit of strong cross-talk these pulses break down when the qubit being manipulated has a resonance close to the higher transition frequencies of the other, however we are still able to find high fidelity pulses numerically.

9:48AM P29.00008 Implementation of a Toffoli Gate with Superconducting Circuits, ARKADY FEDOROV, LARS STEFFEN, MATTHIAS BAUR, ETH Zurich, MARCUS DA SILVA, Raytheon BBN Technologies, ANDREAS WALLRAFF, ETH Zurich — The Toffoli gate is an important primitive in many quantum circuits and quantum error correction schemes. Here we demonstrate the implementation of a Toffoli gate with three superconducting transmon qubits coupled to a microwave resonator [1]. Following Ralph *et al.* [2] we used the third energy level of the transmon qubit to significantly reduce the number of elementary gates needed to implement the Toffoli gate in comparison to approaches using two-level systems only. A similar scheme to realize a Toffoli-class gate has independently been devised on a system of three logical qubits encoded in the states of two qubits and a resonator [3]. Our gate fidelity evaluated by both full process tomography and Monte Carlo process certification is $68.5 \pm 0.5\%$. The results reinforce the potential of macroscopic superconducting qubits for implementation of complex quantum operations and point at the possibility to implement quantum error correction schemes [4].

10:00AM P29.00009 Multiple photon effects in coupled anharmonic oscillators for circuit QED architectures, JAY GAMBETTA, IBM T.J. Watson Research Center, Yorktown Heights, New York 10598, USA, IBM QUANTUM COMPUTING TEAM — In recent years many superconducting qubits have emerged that are essentially weak anharmonic oscillators. When these systems are coupled, due to the weak anharmonicity the major source of error in this system is leakage. In this talk I will present a method for reducing leakage when implementing a two qubit gate. I will also show that due to this weak anharmonicity new multi-photon transitions emerge that can be used for implementing new types of two qubit gates.

10:12AM P29.00010 Observing Resonant Entanglement Dynamics in Circuit QED, J.A. MLYNEK, A.A. ABDUMALIKOV, J.M. FINK, L. STEFFEN, C. LANG, A.F. VAN LOO, A. WALLRAFF, ETH Zurich — We study the resonant interaction of up to three two-level systems and a single mode of an electromagnetic field in a circuit QED setup. Our investigation is focused on how a single excitation is dynamically shared in this fourpartite system. The underlying theory of the experiment is governed by the Tavis-Cummings-model, which on resonance predicts dynamics known as vacuum Rabi oscillations. The resonant situation has already been studied spectroscopically with three qubits [1] and time resolved measurements have been carried out in a tripartite system [2]. Here we are able to observe the coherent oscillations and their $\sqrt{N}$ -enhancement by tracking the populations of all three qubits and the resonator. Full quantum state tomography is used to verify that the dynamics generates the maximally entangled 3-qubit W-state when the cavity state factorizes. The $\sqrt{N}$ -speed-up offers the possibility to create W-states within a few ns with a fidelity of 75%. We compare the resonant collective method to an approach, which achieves entanglement by sequentially tuning qubits into resonance with the cavity.

10:24AM P29.00011 Benchmarking a Teleportation Protocol realized in Circuit QED, MATTHIAS BAUR, ARKADY FEDOROV, LARS STEFFEN, ETH Zurich, MARCUS DA SILVA, Raytheon BBN Technologies, ANDREAS WALLRAFF, ETH Zurich — Teleportation of a quantum state may be used for distributing entanglement between distant qubits in quantum communication and for realizing universal and fault-tolerant quantum computation. Here we demonstrate the implementation of a teleportation protocol, up to the single-shot measurement step, with superconducting qubits coupled to a microwave resonator [1]. Using full quantum state tomography and evaluating an entanglement witness, we show that the protocol generates a genuine tripartite entangled state of all three-qubits. Calculating the projection of the measured density matrix onto the basis states of two qubits allows us to reconstruct the teleported state. Repeating this procedure for a complete set of input states we find an average output state fidelity of 86% for the teleported state.

10:36AM P29.00012 Characterization of a two-transmon processor with individual single-shot qubit readout¹, DENIS VION, FLORIAN ONG, VIVIEN SCHMITT, ROMAIN LAURO, NICOLAS BOULANT, PATRICE BERTET, ANDREAS DEWES, DANIEL ESTEVE, CEA-Saclay, France — We report the characterization of a two-qubit processor implemented with two capacitively coupled tunable superconducting qubits of the transmon type, each qubit having its own non-destructive single-shot readout. The fixed capacitive coupling yields the $\sqrt{i}$ SWAP two-qubit gate for a suitable interaction time. We reconstruct by state tomography the coherent dynamics of the two-bit register as a function of the interaction time, observe a violation of the Bell inequality by 22 standard deviations after correcting readout errors, and measure by quantum process tomography a gate fidelity of 90%.

¹We acknowledge support from the European research contracts MIDAS and SOLID, from ANR Masquelspec and C’Nano.

10:48AM P29.00013 Demonstrating quantum speed-up in a superconducting two-qubit processor¹, ANDREAS DEWES, ROMAIN LAURO, FLORIAN ONG, VIVIEN SCHMITT, DANIEL ESTEVE, PATRICE BERTET, DENIS VION, CEA Saclay, PEROLA MILMAN, Laboratoire Matériaux et Phénomènes Quantiques, Université Paris Diderot — We operate a superconducting quantum processor consisting of two tunable transmon qubits coupled by a swapping interaction, and equipped with non destructive single-shot readout of the two qubits [1]. With this processor, we run the Grover search algorithm among four objects and find that the correct answer is retrieved after a single run with a success probability between 0.52 and 0.67, significantly larger than the 0.25 achieved with a classical algorithm. This constitutes a proof-of-concept for the quantum speed-up of electrical quantum processors [2].

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P30 GQI: Semiconductor Qubits - Communication and Hybridization 259B

8:00AM P30.00001 Circuit Quantum Electrodynamics with Semiconductor Quantum Dots ,

ANDREAS WALLRAFF, TOBIAS FREY, PETER J. LEEK, MATTHIAS BECK, ETH Zurich, ALEXANDRE BLAIS, Université de Sherbrooke, THOMAS IHN, KLAUS ENSSLIN, ETH Zurich — Research on semiconductor quantum dots has tremendously contributed to the understanding of the physics of individual charges and spins in a solid state environment. Typically, quantum dots are investigated by direct current transport measurements or using quantum point contacts for charge sensing. Instead, we have realized a novel device in which a semiconductor double quantum dot is dipole coupled to a GHz-frequency high-quality transmission line resonator. This approach allows us to characterize the properties of the double dot by measuring both its dispersive and dissipative interaction with the resonator [1]. In addition to providing a new readout mechanism, this architecture has the potential to isolate the dots from the environment and to provide long distance coupling between spatially separated dots. These features are expected to improve the potential for realizing a quantum information processor with quantum dots as previously demonstrated for superconducting circuits making use of circuit quantum electrodynamics.

8:12AM P30.00002 Dispersive microwave readout of a silicon double quantum dot¹ ,

ANDREW SCHMIDT, EDWARD HENRY, U.C. Berkeley, QNL, M.G. HOUSE, UCLA, Y.T. WANG, C.C. LO, H. LI, L. GREENMAN, U.C. Berkeley, H. PAN, M. XIAO, UCLA, K.B. WHALEY, U.C. Berkeley, H.W. JIANG, UCLA, E. YABLONOVITCH, J. BOKOR, U.C. Berkeley, I. SIDDIQI, U.C. Berkeley, QNL — Microwave resonators coupled to quantum systems have been used for fast dispersive measurement in several different architectures in solid state and atomic physics. The electronic states of a semiconductor quantum dot represent a promising candidate for quantum information processing. Our work is geared toward developing a fast, non-demolition readout of a semiconductor qubit as realized in silicon by coupling to a superconducting resonant circuit. We report progress on a novel design of a lateral double quantum dot with a unique accumulation gate that allows for control of the spatial location of the 2DEG on the device, allowing the lossy 2DEG to be decoupled from the resonator.

¹This work is supported by the DARPA-QuEST program.

8:24AM P30.00003 Coupling a single charge in a nanowire double quantum dot to a high-Q superconducting microwave resonator¹ ,

K.D. PETERSSON, M.D. SCHROER, L.W. MCFAUL, M. JUNG, J.R. PETTA, Department of Physics, Princeton University, Princeton, New Jersey 08544 — In the field of circuit quantum electrodynamics (cQED), superconducting microwave cavities have provided an important tool with which to probe single superconducting qubits and mediate interactions between distant qubits [1,2]. In view of applying the cQED architecture to semiconductor qubits [3,4], we have integrated a tunable InAs nanowire double quantum dot (DQD) into a high-Q (> 2000), high frequency (~ 6 GHz) niobium microwave resonator. Our design enables a dipole coupling of ~ 40 MHz between the DQD and cavity. We will present experimental results demonstrating how the microwave cavity can be used to explore coherence in nanowire DQDs and discuss prospects for achieving the strong coupling regime.

8:36AM P30.00004 Communication between spin qubits with microwave photons ,

RUSKO RUSKOV, CHARLES TAHAN, Laboratory for Physical Sciences, College Park, MD 20740, U.S.A. — We consider possibilities of quantum state transfer between spin qubits (e.g. electrons in quantum dots) utilizing a microwave transmission line and a tunable coupler. We outline the possibility for optimal quantum transfer between qubit nodes depending on qubit-resonator coupling strengths and tunability, and in the presence of imperfections. Implications of such systems to practical quantum computing in silicon and/or GaAs quantum dots are considered.

8:48AM P30.00005 Spin echo measurements for hybrid qubit systems ,

HANS MALISSA, Department of Electrical Engineering, Princeton University, DAVID SCHUSTER, Department of Physics, University of Chicago, ALEXEI TYRYSKHIN, ANDREW HOUCK, STEPHEN LYON, Department of Electrical Engineering, Princeton University — We have performed electron spin echo measurements on donor spins in silicon samples using micro resonator structures fabricated in thin superconducting niobium films on sapphire substrates. The ability to implement refocusing pulses is an important constituent towards the realization of spin memories for hybrid superconducting/spin qubit applications. The resonators consist of quarter wavelength sections of coplanar waveguide with one end shorted and the other end capacitively coupled to a common feed line. These devices are suitable for pulsed ESR experiments on a commercial spectrometer at microwave frequencies between 9 and 10GHz, and in-plane magnetic fields of about 0.35T, which is well below the critical field of the thin film superconductor. Samples are flip-chip mounted on the resonator, and the magnetic component of the microwave radiation that extends into the sample is used for ESR excitation and detection. The high filling factor due to the small resonator size and the high quality factors that can be obtained with superconductors lead to high sensitivity to small numbers of spins, making our devices an attractive alternative to conventional resonators for certain ESR applications. The low microwave power requirements are appealing for low temperature measurements.

9:00AM P30.00006 Long-distance spin-spin coupling via floating gates ,

LUKA TRIFUNOVIC, University of Basel, OLIVER DIAL, Harvard University, MIRCEA TRIF, JAMES WOOTTON, University of Basel, REDJET ABEBE, AMIR YACOBY, Harvard University, DANIEL LOSS, University of Basel — The electron spin is a natural two level system that allows a qubit to be encoded. When localized in a gate defined quantum dot, the electron spin provides a promising platform for a future functional quantum computer. The essential ingredient of any quantum computer is entanglement—between electron spin qubits—commonly achieved via the exchange interaction. Nevertheless, there is an immense challenge as to how to scale the system up to include many qubits. Here we propose a novel architecture of a large scale quantum computer based on a realization of long-distance quantum gates between electron spins localized in quantum dots. The crucial ingredients of such a long-distance coupling are floating metallic gates that mediate electrostatic coupling over large distances. We show, both analytically and numerically, that distant electron spins in an array of quantum dots can be coupled selectively, with coupling strengths that are larger than the electron spin decay and with switching times on the order of nanoseconds.

9:12AM P30.00007 Quantum gates between non-neighboring spin qubits¹ ,

JIANJIA FEI, YUN-PIL SHIM, University of Wisconsin-Madison, SANGCHUL OH, XUEDONG HU, University at Buffalo, SUNY, MARK FRIESEN, University of Wisconsin-Madison — In quantum circuits involving many qubits, we usually need to perform gates such as CNOT between qubits that are not proximal. For spin qubits, this requires intermediate gate operations because the exchange interaction is very short ranged. Here, we consider three quantum dots in a linear array. We explore the effective coupling between the two outer spins mediated by the central spin. By using the central spin as a “bus”, we show how to efficiently perform gates such as CNOT between the outer spins. We find that arbitrary two-qubit gates can be achieved by applying the bus operations repetitively, with additional single-qubit rotations.

¹Work supported by DARPA-QuEST

9:24AM P30.00008 Resonant Adiabatic Passages of Spin Qubits¹, SANGCHUL OH, Department of Physics, University at Buffalo, The State University of New York, YUN-PIL SHIM, MARK FRIESEN, Department of Physics, University of Wisconsin-Madison, XUEDONG HU, Department of Physics, University at Buffalo, The State University of New York — We study adiabatic quantum teleportation through a spin chain with XX and Heisenberg couplings. We show that an adiabatic quantum teleportation protocol on a three-spin chain can be mapped exactly onto two parallel and coherent adiabatic passage channels, one for each spin orientation. When the time evolution is non-adiabatic, the information transfer displays a series of resonances where perfect transmission fidelity is achieved. This resonant operation is both fast and robust, indicating a possible new route for implementing robust quantum gates between spin qubits.

¹This work was supported by the DARPA QuEST through AFOSR and NSA/LPS through ARO.

9:36AM P30.00009 Quantum phase transitions in a spin bus system, YUN-PIL SHIM, Department of Physics, University of Wisconsin-Madison, SANGCHUL OH, XUEDONG HU, Department of Physics, University at Buffalo, State University of New York, MARK FRIESEN, Department of Physics, University of Wisconsin-Madison — A spin chain can be used as a quantum data bus to enable long distance interactions and to create multi-qubit entanglement between spin qubits. The operation of the spin bus strongly depends on its ground state properties. When the ground state changes abruptly, quantum phase transitions (QPTs) occur and affect the bus operation. Here, we describe the theory of QPTs induced by an external magnetic field in a Heisenberg spin chain which acts as a spin bus. We study the non-analytic behavior of the entanglement between qubits connected to the spin bus and its scaling properties near a quantum critical point. In some cases, we find the entangling properties actually grow with the length of the chain. We also analyze the magnetically induced anisotropy and disorder effects on the effective interactions between qubits.

9:48AM P30.00010 Coupling semiconductor qubits to phonons via a nanomechanical phoniton system, CHARLES TAHAN, RUSKO RUSKOV, Laboratory for Physical Sciences — We explore the possibility of strongly coupling semiconductor qubit states to nanomechanical resonators (phonons) in silicon. These systems may be relevant to qubit transduction schemes, as supporting technology for quantum information processing, for qubit characterization, and for quantum-enabled devices. Specifically, we consider systems where cavity phonons can interact with suitable qubit states in the 1-10 GHz (and higher) regime (tunable using strain, electric and/or magnetic fields). These results may be useful for several solid-state devices as well as being of interest to the optomechanics community.

10:00AM P30.00011 Phonon Mediated Off-resonant Quantum Dot-Cavity Interaction, ARKA MAJUMDAR, ERIK KIM, MICHAL BAJCSY, ARMAND RUNDQUIST, JELENA VUCKOVIC, E. L. Ginzton Lab, Stanford, CA-94305 — Optically controlled quantum dot (QD) spins coupled to semiconductor microcavities constitute a promising platform for robust and scalable quantum information processing devices. In recent experiments on coupled QD optical cavity systems a pronounced interaction between the dot and the cavity has been observed even for detunings of many cavity linewidths. This interaction has been attributed to an incoherent cavity enhanced phonon-mediated scattering process and is absent in atomic systems. We demonstrate that despite its incoherent nature, this process preserves the signatures of coherent interaction between a QD and a strong driving laser, which may be observed via the optical emission from the off-resonant cavity. Under bichromatic driving of the QD, the cavity emission exhibits spectral features consistent with optical dressing of the QD transition, namely Rabi side-bands. These cavity emission measurements are more akin to absorption measurements of a strongly driven QD rather than resonance fluorescence measurements. In addition to revealing new aspects of the off-resonant QD-cavity interaction, this result provides a new, simpler means of coherently probing QDs and opens the possibility of employing off-resonant cavities to optically interface QD-nodes in quantum networks.

10:12AM P30.00012 Rabi-Vibronic resonance at large number of vibrational quanta¹, MIKHAIL RAIKH, RACHEL GLENN, University of Utah — Rabi oscillations of a resonantly driven two-level system (qubit) which is linearly coupled to a cavity (vibrational mode) with frequency, ω_0 , much smaller than the driving frequency, are studied theoretically. We show that, for small coupling constant $\lambda \ll 1$, Rabi oscillations are strongly modified in the vicinity of the *Rabi-vibronic resonance* $\Omega_R = \omega_0$, where Ω_R is the Rabi frequency proportional to the amplitude of the driving field. The width of the resonance is shown to be $(\Omega_R - \omega_0) \sim \lambda^{4/3} \omega_0$, and is much larger than the polaronic frequency shift, $\lambda^2 \omega_0$. We show that within the resonant domain of Ω_R the actual frequency of the Rabi oscillations exhibits bistable behavior as a function of Ω_R . Most importantly, within the resonant domain, the oscillator is highly excited, which allows one to treat it classically. Decay of the Rabi oscillations due to losses in the cavity and spontaneous emission of two-level system are also studied.

¹Supported by NSF DMR-0808842 and MRSEC DMR-1121252.

10:24AM P30.00013 Photon heralded entanglement between radiatively mismatched matter qubits, ZHEXUAN GONG, LUMING DUAN, Department of Physics and MCTP, University of Michigan — Photon heralded entanglement usually requires well matched radiative characteristics of two matter-based qubits. In practice, we may want to entangle two solid-state or atomic qubits with different radiative lifetime, or to entangle a solid-state qubit with an atomic qubit that has significant mismatch in lifetime and transition frequency. We propose a protocol that can effectively shape the emitted photon pulses of two matter qubits to a common analytically known function by simply tuning the classical laser fields applied to each qubit. Entanglement fidelity and success rates are found to be promising under current experimental conditions.

10:36AM P30.00014 Fast optically-controlled two-qubit operation for cavity-coupled semiconductor quantum dots, DMITRY SOLENOV, SOPHIA E. ECONOMOU, THOMAS L. REINECKE, Naval Research Laboratory — Electron spin qubit systems based on charged InAs/GaAs quantum dots have demonstrated long coherence times and the capability of ultra fast single- and two-qubit operations in a configuration when two dots are tunnel-coupled. Designing fast two- and multi-qubit gates for spatially-separated quantum dots is currently an important challenge. We propose fast optically controlled design where a two-qubit gate is mediated by a photonic crystal cavity mode. The design addresses the challenge of scalability and does not require quantum dots to have the same energies. The proposed gate scheme is also compatible with available optically induced single qubit rotations.

10:48AM P30.00015 H1 Photonic Crystal Microcavities for Quantum Information, JENNA HAGE-MEIER, Physics Department, University of California Santa Barbara, USA, CRISTIAN BONATO, Huygens Laboratory, Leiden University, The Netherlands, TUAN-ANH TRUONG, Materials Department, University of California Santa Barbara, USA, HYOCHUL KIM¹, Physics Department, University of California Santa Barbara, USA, PIERRE PETROFF, Materials Department, University of California Santa Barbara, USA, DIRK BOUWMEESTER, Physics Department, University of California Santa Barbara, USA and Huygens Laboratory, Leiden University, The Netherlands — Semiconductor quantum dots coupled to photonic crystal microcavities show promise for quantum information processing in solid-state systems. For many applications, the cavity mode needs to have high extraction efficiency and unpolarized emission. Here we describe a possible implementation using the two orthogonally-polarized, spectrally-degenerate dipole modes of the H1 photonic crystal microcavity. By modifying the shape of the far-field profile, high collection efficiency from the H1 cavity modes can be achieved while maintaining a high cavity quality factor. We optimize and experimentally measure the far-field profiles of our cavities, which show good agreement with simulations. We also implement techniques to minimize the energy splitting of the two dipole modes due to fabrication imperfections, which are compatible with the far-field optimization.

¹Current address: ECE Department, IREAP, University of Maryland, College Park, Maryland 20742, USA

Wednesday, February 29, 2012 8:00AM - 10:36AM – Session P31 DCMP: Topological Insulators: Disorder 260

8:00AM P31.00001 Disordered topological conductor, KUN WOO KIM, California Institute of Technology, ALEXANDRA JUNCK, Freie Universitt Berlin & California Institute of Technology, DORON BERGMAN, California Institute of Technology, TAMI PEREG-BARNEA, McGill University & California Institute of Technology, GIL REFAEL, California Institute of Technology, FELIX VON OPPEN, Freie Universitt Berlin — A topological conductor, like a topological insulator is a system in which the bands are characterized by non-trivial topological invariants such as the Chern numbers. However, unlike a topological insulator, in this system the Fermi energy does not lie in an energy gap but instead intersects at least one of the bulk bands. Although not an insulator the topological conductor supports chiral edge modes. In this work we consider a disordered topological conductor and analyze its properties. In particular we find that moderate disorder reduces the edge conductivity from its quantum value and stronger disorder increases it before the whole system is localized and the conductivity drops to zero. This effect is seen numerically on a lattice system and analytically in a disorder averaged continuum model.

8:12AM P31.00002 Dislocations and their braiding in topological insulators, ANDREJ MESAROS, Department of Physics, Boston College, VLADIMIR JURICIC, JAN ZAAENEN, Instituut-Lorentz, Leiden University — We demonstrate the fundamental importance of crystal lattice dislocations in two-dimensional topological insulators. These defects characterize the topological state through the appearance of electronic localized midgap states. The states turn out to be robust even for the class of materials where they are not protected. At the same time, these localized electronic states have interesting quantum properties. We show that adiabatic braiding of dislocations, which can be achieved using lattice shear induced dislocation glide, brings out the quantum statistics of the electronic bound states.

8:24AM P31.00003 Study of the robustness of two dimensional topological insulators, DANIEL GOSALBEZ-MARTINEZ, Departamento de Fisica Aplicada, Universidad de Alicante, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory and Departamento de Fisica Aplicada, Universidad de Alicante, JUAN JOSE PALACIOS, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid — Two dimensional topological insulators present gapless spin filtered edge states which are topologically protected against backscattering. As long as disorder does not mix the states of opposite edges or with bulk ones, these states contribute to the two terminal conductance as a single quantum channel regardless of the amount of non-magnetic disorder present in the sample. We address this problem studying the effect of different types of disorder: constrictions and Anderson disorder, for two different materials that have been predicted to present the quantum spin Hall insulator phase, graphene and a bilayer of Bi(111). We also study the effect of the zigzag edge reconstruction of graphene over the robust behavior of the edge states. We describe their electronic structure using an orthogonal tight-binding model in the Slater-Koster approximation including the intra-atomic spin-orbit interaction. The conductance is computed using the Landauer formula making use of the ALACANT transport package.

8:36AM P31.00004 Investigating Impurities on 3D Topological Insulators with Multiple Scattering Theory, ROBERT VAN WESEP, University of Tennessee - Knoxville/Oak Ridge National Lab — Recently a new class of materials, three-dimensional topological insulators (3DTI), have generated significant theoretical and experimental interest due to surface states (SS) exhibiting linear dispersion at a Dirac point that are protected by time-reversal symmetry (TRS). Using magnetism to break TRS is of particular interest, especially via the deposition of magnetic impurities (MI) on the 3DTI surface. Experimental studies are in the early stages and consensus on the effect of MI of 3DTI SS has yet to be reached. Multiple scattering theory (MST) has proven useful in investigating surfaces, impurities and disordered systems and provides an ideal framework for first-principles, computational study. This presentation will report on progress in adapting MST to 3DTI systems with impurities.

8:48AM P31.00005 LDOS Multifractal Hunter's Guide to Dirty Topological Insulators, MATTHEW FOSTER, Rutgers, the State University of New Jersey — We compute the multifractal spectra associated to local density of states (LDOS) fluctuations due to weak quenched disorder, for a single Dirac fermion in two spatial dimensions. Our results are relevant to the surfaces of Z_2 topological insulators such as Bi_2Se_3 and Bi_2Te_3 , where LDOS modulations can be directly probed via scanning tunneling microscopy. We find a qualitative difference in spectra obtained for magnetic versus non-magnetic disorder. Randomly polarized magnetic impurities induce quadratic multifractality at first order in the impurity density; by contrast, no operator exhibits multifractal scaling at this order for a non-magnetic impurity profile. For the time-reversal invariant case, we compute the first non-trivial multifractal correction, which appears at two loops (impurity density squared). We discuss spectral enhancement approaching the Dirac point due to renormalization, and we survey known results for the opposite limit of strong disorder.

9:00AM P31.00006 Effects of Strong Disorder in a 3-Dimensional Topological Insulators: Phase Diagram and Mapping of the Z_2 Invariant, BRYAN LEUNG, Rutgers University, EMIL PRODAN, Yeshiva University — We study the effect of strong disorder in a 3-dimensional topological insulators with time-reversal symmetry and broken inversion symmetry. Using level statistics analysis, we demonstrate first the persistence of delocalized bulk states even at large disorder. The delocalized spectrum displays the levitation and pair annihilation effect, indicating that the delocalized states continue to carry the Z_2 invariant after the onset of disorder. The Z_2 invariant is computed via twisted boundary conditions using a novel and efficient numerical algorithm. We demonstrate that the Z_2 invariant remains well defined and quantized even after the spectral gap closes and becomes filled with dense localized states. In fact, our results indicate that the Z_2 remains quantized until the mobility gap closes or until the Fermi level touches the mobility edge. Based on such data, we compute the phase diagram as function of disorder strength and position of the Fermi level.

9:12AM P31.00007 Strong potential impurities on the surface of a three-dimensional topological insulator, ANNICA M. BLACK-SCHAFFER, Uppsala University, ALEXANDER V. BALATSKY, Los Alamos National Laboratory — Topological insulators (TIs) are said to be stable against non-magnetic impurity scattering due to suppressed backscattering in the Dirac surface states. We solve a lattice model of a three-dimensional TI in the presence of strong potential impurities on the surface and find that both the Dirac point and low-energy states are significantly modified: low-energy impurity resonances are formed that produce a peak in the density of states near the Dirac point, which is destroyed and split into two nodes that move off-center. The impurity-induced states penetrate up to 10 layers into the bulk of the TI. These findings demonstrate the importance of bulk states for the stability of TIs and how they can destroy the topological protection of the surface. Extensions to sub-surface and extended defects, as well as direct comparisons to recent experimental results are also made.

9:24AM P31.00008 Disorder induced quantized conductance with fractional value and universal conductance fluctuation in three-dimensional topological insulators, LEI ZHANG, JIANING ZHUANG, Department of Physics, The University of Hong Kong, YANXIA XING, Department of Physics, The University of Hong Kong; Department of Physics, Beijing Institute of Technology, JIAN WANG, Department of Physics, The University of Hong Kong, DEPARTMENT OF PHYSICS, THE UNIVERSITY OF HONG KONG TEAM, DEPARTMENT OF PHYSICS, BEIJING INSTITUTE OF TECHNOLOGY COLLABORATION — We report a theoretical investigation on the conductance and its fluctuation of three-dimensional topological insulators (3D TI) in Bi_2Se_3 and Sb_2Te_3 in the presence of disorders. Extensive numerical simulations are carried out. We find that in the diffusive regime the conductance is quantized with fractional value. Importantly, the conductance fluctuation is also quantized with a universal value. For 3D TI connected by two terminals, three independent conductances G_{zz} , G_{xx} and G_{zx} are identified where z is the normal direction of quintuple layer of 3D TI. The quantized conductance are found to be $\langle G_{zz} \rangle = 1$, $\langle G_{xx} \rangle = 4/3$ and $\langle G_{zx} \rangle = 6/5$ with corresponding quantized conductance fluctuation 0.54, 0.47, and 0.50. The quantization of average conductance and its fluctuation can be understood by theory of mode mixing. The experimental realization that can observe the quantization of average conductance is discussed.

9:36AM P31.00009 Conducting state of GeTe by defect-induced topological insulating order, JINWOONG KIM, Department of Physics, Pohang University of Science and Technology, SEUNG-HOON JHI, Department of Physics and Division of Advanced Materials Science, Pohang University of Science and Technology — Topological insulating order protected by time-reversal symmetry is robust under structural disorder. Interestingly, recent studies on phase change materials like GeSbTe showed that their topological insulating order is sensitive to atomic stacking sequences. It was also shown that their structural phase transition is correlated with topological insulating order. GeTe, a well-known phase change material, is trivial insulator in its equilibrium structure. In this study, we discuss how atomic defects such as Ge tetrahedral defect observed in amorphous GeTe can change its topological insulating order based on first-principles calculations and model Hamiltonian. We also investigated the critical density of such tetrahedral defects to induce topological insulating order in GeTe. Our study will help explore hidden orders in GeTe.

9:48AM P31.00010 Mapping the conductivity tensor of disordered topological insulators in the presence of magnetic fields¹, EMIL PRODAN, YU XUE, Department of Physics, Yeshiva University — Transport measurements on topological insulators revealed extremely interesting effects and generated data that contain extremely valuable information. It is now possible to control the carriers' concentration using finely tuned gate voltages and to do the transport measurements under controlled applied magnetic fields. As such, accurate maps of the conductivity tensor are now available, as function of the Fermi level and the magnetic field strength. To extract useful information, we need a quantitative theory of charge transport for aperiodic systems in presence of magnetic fields. Such theory has been developed in the past using C^* -Algebras and Non-Commutative calculus, the result being closed and exact formulas for the conductivity tensor. In this talk we explain how to manipulate the algebras and how to implement the non-commutative calculus on a computer, in order to compute the conductivity tensor of topological insulating materials in the presence of disorder and magnetic fields. Quantitative simulations of the transport experiments on 2D (and possibly 3D) topological insulators will be presented. Since the methodology can treat disorder and magnetic fields in the same time, it enable us to reproduce, for example, the quantization and the plateaus of the Hall conductance.

10:00AM P31.00011 Magnetic field induced Quasi Helical Liquid state in a disordered 1D electron system with strong spin-orbit interaction, ANDERS STRÖM, University of Gothenburg, Sweden, BERND BRAUNECKER, Universidad Autónoma de Madrid, Spain, G.I. JAPARIDZE, Andronikashvili Institute of Physics, Georgia and Ilia State University, Georgia — We study the crossover from a Luttinger liquid to a quasi-helical liquid state in a one-dimensional system of interacting electrons with strong spin-orbit interaction in the presence of a transverse magnetic field, which leads to a gap for one-half of the conducting modes. In particular, we study the effect of gap opening by electron localization in the presence of non-magnetic disorder. We show that the localization length has a nonuniform behavior as a function of the magnetic field. With increasing field, the localization length grows from its zero-field Luttinger-liquid value to a maximum, after which it crosses over to again smaller values corresponding to the localization length of spinless fermions.

10:12AM P31.00012 Delocalized States and Topological Edge States of Quantum Walks in Random Environment, HIDEAKI OBUSE, Karlsruhe Institute of Technology, Germany, NORIO KAWAKAMI, Kyoto University, Japan — The quantum walk (QWs) describe quantum mechanical time evolution of particles, which is identified as random walks when systems are brought to classical limit. QWs can be applied for efficient algorithms of quantum computation and have been realized in experiments. Remarkably, QWs realized by many experiments possess chiral symmetry. Thereby, QWs in a one dimensional (1D) space possibly have non-trivial topological phases and show edge states near boundaries of the system. In this work, we consider QWs interacting with spatial and temporal disorders and study how the edge states of QWs are influenced. Even by introducing the weak spatial disorder to the QWs, the edge states are robust. However, in the strong disorder limit, the energy gap vanishes and the edge states disappear. We found that critical states due to the Anderson transition in the 1D chiral class alternatively appear at energy $\omega = 0$ in this case. Significantly, these critical states also appear at $\omega = \pm\pi/2$ for any strength of static disorder, since the extra sublattice symmetry of the time-evolution operator U makes $\omega = \pm\pi/2$ singular. Consequently, for the QWs with relatively weak spatial disorder, the edge states, critical states, and Anderson localized states are coexist.

10:24AM P31.00013 The strong side of weak topological insulators, YAACOV KRAUS, ZOHAR RINGEL, ADY STERN, Weizmann Institute of Science — Three-dimensional topological insulators are classified into "strong" (STI) and "weak" (WTI) according to the nature of their surface states. While the surface states of the STI are topologically protected, in the WTI they are believed to be very fragile to disorder. In this work we show that the WTI surface states are actually protected from any random perturbation which does not break time-reversal symmetry, and does not close the bulk energy gap. Consequently, the conductivity of metallic surfaces in the clean system will remain finite even in the presence of strong disorder of this type. In the weak disorder limit the surfaces are perfect metals, and strong surface disorder only acts to push them inwards. We find that WTI's differ from STI's primarily in their anisotropy, and that the anisotropy is not a sign of their weakness but rather of their richness.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - BiFeO₃ 261

8:00AM P32.00001 Inelastic neutron scattering study of spin-wave from single crystal BiFeO₃

, GUANGYONG XU, ZHIJUN XU, Brookhaven National Laboratory, JINSHENG WEN, UC Berkeley, MATTHEW STONE, Oak Ridge National Laboratory, GENDA GU, STEPHEN SHAPIRO, Brookhaven National Laboratory, R.J. BIRGENEAU, UC Berkeley, CHRIS STOCK, PETER GEHRING, NIST Center for Neutron Research — BiFeO₃ is one of the most promising multiferroic materials for device applications in spintronics and memory devices. There have been a number of studies on electric field tuning of antiferromagnetic domains, as well as possible E-field control of spin-waves in this material. The potential of controlling spin dynamics using electric field is extremely appealing. However, so far there have been very limited work on the direct measurements of spin-waves in BiFeO₃, mostly due to lack of large size single crystals. We will present our recent inelastic neutron scattering studies on a single crystal BiFeO₃, showing the full spin-wave spectrum in three-dimensions. A classical spin-wave model can be used to describe the results in details. The coupling parameters and spin-wave velocities have been obtained, and are in good agreements with those obtained in Raman measurements.

8:12AM P32.00002 Local Raman spectroscopic study of BiFeO₃ strained states

, YEN-CHIN HUANG, YI-CHUN CHEN, FENG-NAN CHU, Department of Physics, National Cheng Kung University, WEN-I LIANG, HSIANG-JUNG CHEN, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University — Among single-phase multiferroic materials, BiFeO₃ (BFO) has relatively high Curie and Néel temperatures, which possesses ferroelectric and antiferromagnetic couplings at room temperature, so is motivated for novel device applications. Recent studies had shown piezoelectric and magnetic properties of BFO in strained states varied significantly. For BFO epitaxial films grown on LaAlO₃ substrate, high piezoelectric coefficient and spontaneous ferromagnetic moments had been demonstrated in a new kind of morphotropic tetragonal-rhombohedral phase boundary driven by substrate strain. In this study, we used Raman spectrum to investigate the local BFO distorted structure under substrate strain or strain caused by external electric fields. The crystal structure of BFO under compressive substrate strain is monoclinically distorted. The ordering of the monoclinic structures could also be controlled by electric field. These two kinds of strained states were locally studied by atomic force microscopy (AFM) equipped with on-axis Raman measurement. This study provided the basic physical insight of unique physical properties depended on distorted structures.

8:24AM P32.00003 Unambiguous phonon mode assignment in multiferroic BiFeO₃ single crystals

, CHRISTIANNE BEEKMAN, University of Toronto, SANG-WOOK CHEONG, Rutgers University, KENNETH BURCH, University of Toronto — In Bismuth ferrite (BiFeO₃) antiferromagnetic and ferroelectric order parameters coexist at room temperature, making this material an excellent candidate for new functionalities, such as electrical control of magnetism. Despite extensive reports on Raman scattering experiments on single crystals and thin films, controversy still remains in the observation and assignment of the phonon mode symmetries. We present polarized micro-Raman spectroscopy of single crystals ((1 0 0)_{cubic} surface) with uniform ferroelectric polarization. Careful examination of the Raman spectra upon crystal rotation enables us to unambiguously assign the (A_1 , E_x and E_y) modes. We will show that ambiguity is easily introduced by slight misalignment of the crystal and that the crystal rotation is necessary to reach unambiguous mode assignment. Our method not only results in proper Raman mode assignment, which is necessary to describe the phonons critical for the multiferroic behavior, it also allows study of symmetry breaking and may provide a way to non-invasively check the ferroelectric polarization direction.

8:36AM P32.00004 Multiple Phase Transitions in the model multiferroic BiFeO₃

, JENS KREISEL, CNRS - Grenoble Institute of Technology — Bismuth ferrite BiFeO₃ (BFO) is commonly considered a model system for multiferroics, and is perhaps the only material that is both magnetic and a ferroelectric with a strong electric polarization at 300K [1]. Despite numerous investigations, the crystal structures of BFO as a function of temperature and pressure are still not established and lead to ongoing controversial reports in the literature [1,3]. Besides being a model multiferroic, BFO is also one of the very few materials that present both octahedra tilts and strong cation displacements at room temperature. Here we report the high-pressure phase transitions in BFO by both synchrotron x-ray diffraction and Raman spectroscopy, namely a surprising richness of six phase transitions in the 0–60 GPa range [2-3]. At low pressures, 4 transitions are evidenced at 4, 6, 7 and 11 GPa. In this range, the crystals display in that range unusual large unit cells and complex domain structures, which suggests a competition between complex tilt systems and possibly off-center cation displacements. The non polar Pnma phase remains stable over a large pressure range between 11 and 38 GPa. The two high pressure phase transitions at 38 and 48 GPa are marked by the occurrence of larger unit cells and an increase of the distortion away from the cubic parent perovskite cell. The previously reported insulator-to-metal transition appears to be symmetry breaking. Finally, we will present a new schematic P-T phase diagram for BFO and discuss the recently reported phase transition in highly strained BFO films [4,5] in the light of our high-pressure findings.

9:12AM P32.00005 Phase Transitions in Epitaxial (-110) BiFeO₃ Films from First Principles*¹

, SERGEY PROSANDEEV, University of Arkansas, IGOR KORNEV, Ecole Centrale Paris, LAURENT BELLAICHE, University of Arkansas — The effect of misfit strain on properties of epitaxial BiFeO₃ films that are grown along the pseudo-cubic $\bar{1}10$ direction, rather than along the “usual” [001] direction, is predicted from density functional theory. These films adopt the monoclinic Cc space group for compressive misfit strains smaller in magnitude than $\approx 1.6\%$ and for any investigated tensile strain. In this Cc phase, both polarization and the axis about which antiphase oxygen octahedra tilt rotate *within* the epitaxial plane as the strain varies. Surprisingly and unlike in (001) films, for compressive strain larger in magnitude than $\approx 1.6\%$, the polarization vanishes and two orthorhombic phases of $Pnma$ and $P2_12_12_1$ symmetry successively emerge via strain-induced transitions. The $Pnma$ -to- $P2_12_12_1$ transition is a rare example of a so-called pure “gyrotropic” phase transition, and the $P2_12_12_1$ phase exhibits original interpenetrated arrays of ferroelectric vortices and antivortices. This work is mostly supported by ONR Grants N00014-08-1-0915 and N00014-07-1-0825 (DURIP). *S. Prosandeev, Igor A. Kornev, and L. Bellaiche, Phys. Rev. Lett. 107, 117602 (2011).

9:24AM P32.00006 Nonlinearity in the high-electric-field piezoelectric response of epitaxial BiFeO₃¹, PICE CHEN, REBECCA SICHEL², JIYOUNG JO³, RYAN SMITH, CHANG-BEOM EOM, University of Wisconsin-Madison, OSAMI SAKATA, SPRING-8, ERIC DUFRESNE, Argonne National Laboratory, PAUL EVANS, University of Wisconsin-Madison — The multiferroic material BiFeO₃ provides the means to understand the piezoelectric coupling between lattice strain and ferroelectric polarization. Little is known about the piezoelectric properties of BiFeO₃ under high electric fields. In our study, the transient high-electric-field piezoelectricity of BiFeO₃ was measured at electric fields up to about 300 MV/m using time-resolved x-ray microdiffraction. A linear strain-electric field response with a piezoelectric coefficient of 55 pm/V was observed at electric fields up to 150 MV/m. At higher electric fields, the strain is larger than the value anticipated from the low-field regime, reaching 0.02 at 281 MV/cm. The integrated intensity near the BiFeO₃ (002) Bragg reflection is unchanged in large electric fields, showing that the enhanced piezoelectricity occurs without producing a field-induced phase transition. We also observe a relative increase of diffuse x-ray intensity at high electric fields. We will discuss a model in which the increase of piezoelectricity and diffuse scattering originates from the softening of phonon modes at high electric fields.

³Present address: Gwangju Institute of Science and Technology

9:36AM P32.00007 Ultrafast photostriction in BiFeO₃ thin films, L.Y. CHEN, C.W. LUO, Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan, Y.H. CHU, Department of Materials Science and Engineering, National Chiao Tung University, Hsinchu 300, Taiwan, T. KOBAYASHI, Department of Electrophysics, National Chiao Tung University, Hsinchu 300, Taiwan — The ultrafast dynamics of BiFeO₃ (BFO) thin films was studied by dual-color transient reflectivity measurements ($\Delta R/R$) from 80 K to room temperature. Based on the thickness-dependent propagating time of the photoinduced strain pulse, the sound velocity along [110] direction of BFO is 4.76 km/s. Anisotropic photostriction effect in BFO generated within short time scale of 5 ps is enhanced by the optical rectification effect. Furthermore, the anomalous changes of the temperature-dependent $\Delta R/R$ at 130 K and 210 K may reveal the spin-orbital coupling and magnetoelastic effect in BFO.

9:48AM P32.00008 Photoinduced structural dynamics in BiFeO₃ thin films studied by ultrafast x-ray diffraction¹, D.A. WALKO, E.M. DUFRESNE, J.H. LEE, J.W. FREELAND, Y. LI, H. WEN, Advanced Photon Source, Argonne National Laboratory, P. CHEN, P.G. EVANS, University of Wisconsin-Madison, C. ADAMO, D.G. SCHLOM, Cornell University, J. IHLEFELD, Sandia National Laboratories — We have used time-resolved x-ray diffraction to study the temporal response of multiferroic BiFeO₃ to laser excitation. Above-bandgap light pulses, with 400 nm central wavelength and 50 fs duration, were used to photoexcite 35-nm thick BiFeO₃ films grown by molecular beam epitaxy on SrTiO₃ (001) substrates. The angular shifts of BiFeO₃ Bragg peaks vs. time were recorded with ~100 ps resolution and used to determine the out-of-plane strain in the film. Observed strains range up to several tenths of a percent after excitation and relax on a several-ns timescale. Strains of such magnitude are too large to be explained by thermal expansion alone, but rather appear to be due to screening of the depolarization field by photoexcited carriers. At higher laser fluences, the integrated intensity of the Bragg peak decreases due to transient rearrangement of the atomic lattice on the scale of ~0.1 Å.

10:00AM P32.00009 The valence electronic structure of multiferroic BiFeO₃ from high energy X-ray photo-electron spectroscopy and first principles theory, R. KNUT, Department of Physics and astronomy, Uppsala University, Uppsala, Sweden, S. FALIEV, DIPANJAN MAZUMDAR, O. MRYASOV, ARUNAVA GUPTA, Center for Materials for Information Technology, University of Alabama, O. KARIS, Department of Physics and astronomy, Uppsala University, Uppsala, Sweden, U ALABAMA TEAM, UPPSALA TEAM — BiFeO₃ (BFO) is a multi-functional material with high ferroelectric and magnetic ordering temperature. Here we have investigated the electronic structure of (001) oriented 100nm rhombohedral BFO thin films using high energy X-ray photoelectron spectroscopy (XPS). By making use of the energy dependence of the relative cross sections for different states, we were able to selectively probe the elemental contributions to the valence band. At high energies, states with high main quantum number will have a higher relative probability for photo-ionization, i.e., the Bi 6s and 6p contributions in the valence region are enhanced relative to the Fe 3d and O 2p. We find that the Bi 6p states hybridize strongly with the valence band dominated by the Fe 3d and O 2p states, resulting in a splitting of the 3d states due to bonding and anti-bonding combinations with the Bi 6p. Our results thus suggest that a previously relatively ignored electronic interaction needs to be considered for BFO and related Bi-TMOs. Ab initio calculations indicate the importance of screened Coulomb correlations to describe Bi and Fe electronic states.

10:12AM P32.00010 Direct characterization of the surface layer of BiFeO₃ Single Crystals, NEUS DOMINGO, JACKELINE NARVAEZ, Centre d'Investigació en Nanociència i Nanotecnologia CIN2, CSIC-ICN, Campus Bellaterra, 08193 Barcelona, Spain, XAVI MARTÍ, Charles University in Prague, Faculty of Mathematics and Physics, Czech Republic, MARIN ALEXE, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle, Germany, GUSTAU CATALAN, Centre d'Investigació en Nanociència i Nanotecnologia CIN2, CSIC-ICN, Campus Bellaterra, 08193 Barcelona, Spain — A surface layer different from the bulk was found in single crystals of BiFeO₃, and was analyzed with different techniques such as surface impedance and grazing incidence x-ray diffraction, showing an specific phase transition at T* ~ 275 °C. Local physical characterization studies have been performed with different AFM techniques, such as Piezoelectric Force Microscopy (PFM), Scanning Kelvin Probe Microscopy (SKPM) and Force Modulated Microscopy (FMM) at different temperatures up to 300°C. The thin superficial skin layer is found to be an electrically "dead" layer with a thickness of 6 +/- 1 nm and different thermal expansion coefficient with respect to the bulk. The sharp thermal expansion of the surface layer at T* facilitates its mechanical decoupling from the underlying crystal at the transition temperature, enabling direct access to the sub-surface region using scanning probe microscopy techniques. A distribution of near-surface ferroelectric domains is found in a region of less than 200 nanometers depth under the surface. These nanodomains organize in a hierarchical metastructure on top of the existing bulk domains. The symmetry and properties of these sub-surface nanodomains will be discussed.

10:24AM P32.00011 First-principles investigation of phase-change effects in multiferroics¹, OSWALDO DIÉGUEZ, OTTO E. GONZÁLEZ-VÁZQUEZ, JACEK C. WOJDEŁ, JORGE ÍÑIGUEZ, ICMAB-CSIC, Campus de la UAB, 08193 Bellaterra — Using first-principles calculations we have characterized new phases of bulk multiferroic materials that are close in energy to the ground state, but that display very different properties. This suggests that the application of electric fields could induce phase changes that would involve large effects of different kinds. In particular, (i) we have found stable supertetragonal bulk phases for the prototype multiferroic bismuth ferrite [Diéguez *et al*, Phys. Rev. B **83**, 094105 (2011)], and (ii) we propose to use a solid solution of bismuth ferrite and bismuth cobaltite to create a material where it is possible to switch between two very different phases in a way that involves strong piezoelectric, electric, and magnetoelectric effects [Diéguez and Íñiguez, Phys. Rev. Lett. **107**, 057601 (2011)].

10:36AM P32.00012 Magnetic and structural properties of BiFeO₃ thin films grown epitaxially on SrTiO₃/Si substrates¹, DANIEL CURRIE, RYAN LAUGHLIN, GOKUL RADHAKRISHNAN, WEERASINGHE PRIYANTHA, ROCIO CONTRERAS-GUERERRO, RAVINDRANATH DROOPAD, NIKOLETA THEODOROPOULOU, Texas State University, San Marcos — Commensurate growth of SrTiO₃ (STO) on Si using molecular beam epitaxy (MBE) has been achieved. STO on Si is used as a virtual substrate to enable the growth of BiFeO₃ (BFO). Having a crystalline oxide surface on Si is an enabler for deposition of various functional oxides that would not have been possible directly on silicon. A systematic study of the dependence of the magnetic and structural properties of BFO on the growth conditions, such as O₂ plasma pressure and film thickness, is performed. The crystalline nature of the BFO film has been confirmed by X-Ray diffraction showing the expected peak positions for (100) oriented oxide films with no additional, unidentified peaks. The BFO/STO/Si films exhibit antiferromagnetic behavior with high transition temperatures, thus leading to the possibility of room temperature magnetoelectric coupling-based devices integrated onto Si CMOS circuitry. Thinner films at lower O₂ plasma pressures exhibit stronger magnetic characteristics.

¹This work was supported by AFOSR under grant FA 9550-10-0133.

10:48AM P32.00013 Magnetoelectric and Ferroelectric Properties of BiFeO₃/Ni film Deposited by Pulsed Laser Deposition, LI YAN, MUJIN ZHUO, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, ZHIGUANG WANG, JIANJUN YAO, JIEFANG LI, DWIGHT VIEHLAND, Dept. of Materials Science and Engineering, Virginia Tech, QUANXI JIA, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — To fabricate a layer by layer (2-2) magnetoelectric (ME) sensor, ferroelectric (FE) BiFeO₃ film was directly deposited on ferromagnetic (FM) nickel foil by pulsed laser deposition (PLD) without oxide or noble metal buffer layer, which significantly lowers the cost of ME and FE devices, and makes it possible to deposit longer ME and FE bendable band by PLD. X-ray diffraction and transmission electron microscopy analysis confirmed that the BiFeO₃ film was successfully deposited on the top of nickel foil. The BiFeO₃ film had a saturation polarization and a piezoelectric d33 coefficient of 69 $\mu\text{C}/\text{cm}^2$ and 52 pm/V respectively. The ME coefficient of the sample was 4mV/cmOe which was measured under 1 Oe AC magnetic field at 1 kHz frequency.

Wednesday, February 29, 2012 8:00AM - 10:48AM – Session P33 GERA: Physics of Photovoltaics and other Electricity Production 106

8:00AM P33.00001 Light Reflection and Absorption by Free Standing Titania Nanotube Arrays¹, ABDELMOULA MOHAMED, JEFFREY SOKOLOFF, MENON LATIKA, Northeastern University, Boston, MA 02115 — Newly discovered titania nanotube arrays fabricated by anodization have become the main interest of many research groups around the world, mainly due to their potential use for solar energy harvesting. Light conversion to electron-hole pairs can occur in the surface area of these nanotubes, resulting from their very high aspect ratio and the low recombination probability in the titania surface. In our work we have investigated the transmission of light through the nanotubes for different tube lengths, to explore the penetration depth for various wavelengths in the nanotube array. Specifically, we have investigated the reflection and transmission of light incident from both the open and closed sides of the nanotubes. We find that the reflectivity is generally noticeably smaller for light incident on the open end, but the transmission is about the same, implying greater absorption for light incident on the open side, although for wavelengths close to 400nm, the reflectivity from the open side becomes larger than that from the closed side. We will present a theoretical model to explain our experimental results. The model treats wave propagation along the tubes in the eikonal approximation, and wave propagation transverse to the tubes as Bloch waves.

¹NSF ECCS Grant # 0925285 is acknowledged.

8:12AM P33.00002 A quantum-mechanical study of ZnO and TiO₂ based DSC, FRANCESCA RISPLENDI, GIANCARLO CICERO, Material Science and Chemical Engineering Department, Politecnico of Torino, C.so Duca degli Abruzzi 24, 10129, Torino, Italy, GIUSEPPE MALLIA, Thomas Young Centre, Department of Chemistry, Imperial College London SW7 2AZ, UK, LEONARDO BERNASCONI, Rutherford Appleton Laboratory, Oxfordshire OX11 0QX, UK, NICHOLAS HARRISON, Thomas Young Centre, Department of Chemistry, Imperial College London SW7 2AZ, UK; Daresbury Laboratory, Cheshire, WA4 4AD, UK — Since the pioneering work of Graetzel, Dye Sensitized Cells (DSCs) have attracted great attention as cheap and effective solar power devices based on wide bandgap metal oxide electrode. Optimization of the DSC is a challenging task as it is a highly complex interacting molecular system. Surface properties of the metal-oxide and proper sensitization with dyes may strongly affect the efficiency. Optimized DSCs based on TiO₂ photoanodes and organic dye have reached conversion efficiency of about 10% whereas the efficiency of ZnO based DSC has been found to be much lower, although this material has photochemical properties similar to TiO₂, in general due to the nature of the binding between sensitizer and semiconductor. For this reason understanding how anchoring groups interact with the metal-oxide is fundamental to shed light on the different behaviour of these materials in DSC. Aim of this work is to address the binding of small organic sensitizers, such as catechol and isonicotinic acid molecules, to TiO₂ and ZnO surfaces, in terms of geometry, stability, electronic structure and absorption properties. To this end, we employed quantum-mechanical simulations based on hybrid DFT and hybrid TDDFT.

8:24AM P33.00003 Band gap engineering and optical properties of tungsten trioxide¹, YUAN PING, Department of Chemistry, University of California, Davis, YAN LI, Computational Science Center, Brookhaven National Laboratory, DARIO ROCCA, Department of Chemistry, University of California, Davis, FRANCOIS GYGI, Department of Applied Science and Department of Computer Science, University of California, Davis, GIULIA GALLI, Department of Chemistry and Department of Physics, University of California, Davis — Tungsten trioxide (WO₃) is a good photoanode material for water oxidation but it is not an efficient absorber of sunlight because of its large band gap (2.6 eV). Recently, stable clathrates of WO₃ with interstitial N₂ molecules were synthesized [1], which are isostructural to monoclinic WO₃ but have a substantially smaller band gap, 1.8 eV. We have studied the structural, electronic, an vibrational properties of N₂-WO₃ clathrates using ab-initio calculations and analyzed the physical origin of their gap reduction. We also studied the effect of atomic dopants, in particular rare gases. Substantial band gap reduction has been observed, especially in the case of doping with Xe, due to both electronic and structural effects. Absorption spectra have been computed by solving the Bethe-Salpeter Equation [2] to gain a thorough insight into the optical properties of pure and doped tungsten trioxide. [1] Q. Mi, Y. Ping, Y. Li., B.S. Brunschwig, G. Galli, H B. Gray, N S. Lewis (preprint) [2]D. Rocca, D. Lu and G. Galli, J. Chem. Phys. 133, 164109 (2010)

8:36AM P33.00004 Aluminum nanoparticles for plasmonic enhancement of light absorption in organic semiconductors¹, HANS ROBINSON, Virginia Tech, LAUREN NEELY, MicroXact, Inc., CHIH-YU JAO, Virginia Tech, VLADIMIR KOCHERGIN, MicroXact, Inc. — The energy conversion efficiency in organic photovoltaic (OPV) devices is low, primarily due to the short exciton diffusion length (10 nm) in organic semiconductors. Much effort is currently devoted to improving the optical absorptivities in OPVs by incorporating plasmonic nanostructures in or near the active layer, which would allow for significantly thinner absorption layers. We suggest that aluminum nanoparticles are a better choice than gold or silver particles for embedded plasmonic structures in OPV active layers. This is due to the high plasmon frequency of Al, which makes it easy to create good overlap between plasmon resonance and semiconductor absorption band in a random mixture of polymer and nanoparticles. We will present both modeling and experimental data to support this hypothesis.

¹Funding: AFOSR contract No. FA9550-10-C-0059

8:48AM P33.00005 Si-SiGe hetero-structure thin-film solar cells using integrated electro-optical modeling, MUHAMMAD KHIZAR, DONGMING MEI, Department of Physics, University of South Dakota, Vermillion, SD 57069 — Heterostructure Si-SiGe thin film solar cells have been designed and optimized using advanced electro-optical theoretical modeling and simulation. Some of the key characteristics such as short-circuit current density (J_{sc}), open circuit voltage (V_{oc}), and fill factor (FF) have been studied for varying concentration of Ge in SiGe buffer layer. The effect of thickness variation of alloyed layer for varying Ge composition ~ 0.1 –10% has been performed. The improvement in the conversion efficiency of these cells was calculated by tailoring the thickness of p+ doped layer. An approach relying on phenomena of improved absorption of the alloys which leads to a gain in the current was explored. Improved infrared response with higher short circuit current has been obtained for about 25 μm thick structures. With the optimized Ge concentration, and the incorporated structure design parameters, as much as 4–6% enhancement in the overall efficiency of the solar cells has been calculated compared to that of the conventional single crystal Si solar cells. Moreover, the efficiency of these cells can further be improved because Si-SiGe based solar cells have improved absorption characteristics and offer minimum operating temperature sensitivity. It is believed that with better understanding of the band-gap engineering of SiGe when used as buffer and junction layers, the overall conversion efficiency of such devices can further be improved and could play a critical role to develop low cost and high efficiency solar cells technology. This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

9:00AM P33.00006 Multiscale Simulation on a Light-Harvesting Molecular Triad¹, GUOXIONG SU, ARKADIUSZ CZADER, University of Houston, DIRAR HOMOUI, Khalifa University, Abu Dhabi, UAE, GABRIELA BERNARDES, SANA MATEEN, MARGARET CHEUNG, University of Houston — We have investigated the effect of solvation and confinement on an artificial photosynthetic material, carotenoid-porphyrin- C_{60} molecular triad, by a multiscale approach and an enhanced sampling technique (Replica Exchange Method). We have developed a combined approach of quantum chemistry, statistical physics, and all-atomistic molecular dynamics simulation to determine the partial atomic charges of the ground-state triad. The confinement effects on the triad were modeled by imposing three sizes of spherocylindrical nanocapsules. The triad is structurally flexible under ambient conditions and its conformation distribution is manipulated by the choice of water models and confinement. Two types of water models (SPC/E and TIP3P) are used for solvation. We have shown that a slight structural difference in the two water models with the same dipole moment can have great distinction in water density, water orientation and the number of hydrogen bonds in the proximity of a large flexible compound such as the triad. Subsequently, it has direct impact on the position of the triad in a confinement as well as the distribution of conformations at the interface of liquid and solid in a finite-size system.

9:12AM P33.00007 The Potential for Hot Carrier Collection from an Amorphous Semiconductor¹, REUBEN COLLINS, Colorado School of Mines, KRISTIN KIRILUK, Abengoa Solar, JEREMY FIELDS, BRIAN SIMONDS, LEVI MILLER, YU-PAN PAI, Colorado School of Mines, TING SU, BAOJIE YAN, JEFFREY YANG, SUBHENDU GUHA, United Solar Ovonic, LLC, ARUN MADAN, MVS Systems, Inc., CRAIG TAYLOR, Colorado School of Mines — The quest for clean, inexpensive sources of energy has produced intense interest in low-cost methods for dramatically increasing the efficiencies of solar cells. One such method is to collect carriers before they lose energy to heat. Here we present strong evidence for such hot carrier transfer in an unlikely place, between the amorphous and crystalline regions of nanocrystalline Si. Nanocrystalline Si is a thin film photovoltaic material formed of Si nanocrystallites imbedded in a hydrogenated amorphous Si matrix. Using a combination of photoluminescence quenching and electron spin resonance measurements as a function of nanocrystalline fraction, we observe clear evidence that above a critical fraction carriers excited in the amorphous region transfer to the nanocrystals rather than relaxing to band tail states of the amorphous silicon matrix. The average nanocrystallite spacing is consistent with estimates of the distance hot carriers can transfer in amorphous silicon before thermalization. This result has implications that extend from improving the stability of amorphous silicon under optical illumination to the development of a new paradigm in solar cell design using nanostructured amorphous absorbers.

¹This material is based upon work supported by the NSF through the Renewable Energy Materials Research Science and Engineering Center

9:24AM P33.00008 Enhanced photocatalytic H_2 production by sub-nanometer Au nanoparticles, SHEN ZHAO, Department of Materials Science and Engineering, Stony Brook University, YAN LI, Computational Science Center, Brookhaven National Laboratory, PEICHUAN SHEN, Department of Materials Science and Engineering, Stony Brook University, DONG SU, Center for Functional Nanomaterials, Brookhaven National Laboratory, ALEXANDER ORLOV, Department of Materials Science and Engineering, Stony Brook University — CdS surfaces were found to exhibit a dramatically enhanced photo-catalytic activity for the water splitting process when loaded with sub-nanometer Au particles, compared to that of bare CdS or CdS modified with other noble metal particles (Pt, Ru, Rh, Pd) with similar co-catalyst loading. As a first step towards understanding the striking photocatalytic activity of Au/CdS, we conducted a detailed characterization of the Au particle samples by combining mass spectroscopy, (scanning) transmission electron microscopy, UV-vis spectroscopy and first-principle calculations. In particular, we carried out systematic studies of the influence of particle size, surface termination and charge state on the structural, electronic and spectroscopic properties of ligand-protected Au nanoparticles using density functional theory and time-dependent density functional theory. The structural and electronic stability of diphosphine-protected Au_9 and Au_{11} cations with composition determined from mass spectroscopy, were confirmed from total energy and electronic structure calculations, while the computed optical absorption spectra were found to be in excellent agreement with UV-vis data. Work is underway to study the interaction between Au particles and Cds.

9:36AM P33.00009 First-principles study of III-V electrode interfaces for photoelectrochemical hydrogen production¹, BRANDON WOOD, TADASHI OGITSU, WOON CHOI, ERIC SCHWEGLER, LLNL — Photoelectrochemical (PEC) cells promise clean, sustainable production of hydrogen fuel using water and sunlight. However, combining solar conversion efficiency with durability in electrolyte solution has proven difficult, in part because the complex chemistry active at the electrode-electrolyte interface remains poorly understood. We use first-principles molecular dynamics simulations and model density-functional calculations to study the structure, stability, and chemical activity of GaP/InP semiconductor electrodes in contact with water. We find that a local bond-topological model is able to capture much of the basic surface chemistry. Interpretation of our results points to the particular importance of surface-adsorbed oxygen in determining the available reaction pathways for photocorrosion and water dissociation. Electronic signatures of the local bond topologies are compared to data from X-ray absorption and emission spectroscopy for insight into actual electrode structure.

¹Prepared by LLNL under Contract DE-AC52-07NA27344.

9:48AM P33.00010 ABSTRACT WITHDRAWN —

10:00AM P33.00011 Photoresistance of $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}$ thin films and $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}/\text{Al}_{0.15}\text{Zn}_{0.85}\text{O}$ multilayers, TIANJING LI, RENZHONG DU, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA, GONGPING LI, School of Nuclear Science and Technology, Lanzhou University, Lanzhou 730000, China, QI LI, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA — Thin films of $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}$ and $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}/\text{Al}_{0.15}\text{Zn}_{0.85}\text{O}$ multilayers have been grown on sapphire substrates by pulsed-laser deposition. P-type $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}$ is an insulator with the band gap of 3.26eV and n-type $\text{Al}_{0.15}\text{Zn}_{0.85}\text{O}$ is a transparent conductor. Under the ultraviolet light irradiation, the $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}$ films show photoresistance (PR) ($\text{PR}=(R_{\text{dark}}-R_{\text{irradiation}})/R_{\text{irradiation}}$) effect of $\sim 340\%$ at room temperature. In bilayers of $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}(\sim 110\text{nm})/\text{Al}_{0.15}\text{Zn}_{0.85}\text{O}(\sim 90\text{nm})$ where a p-n junction is formed, the photoresistance increases to $\sim 8600\%$. The photoresistance dependence on wavelength (300-700nm) measurement shows that the photoresistance effect is observed when the light wavelength is below $\sim 380\text{nm}$. The dependence of the light intensity and the response time of the resistance switching have also been measured and will be discussed. The largely enhanced PR effect in bilayers is probably due to the enhancement of the PR effect in p-n junctions. The increased photosensitivity indicates that the $\text{Li}_{0.2}\text{Zn}_{0.8}\text{O}/\text{Al}_{0.15}\text{Zn}_{0.85}\text{O}$ multilayers are promising for UV photodetection applications.

10:12AM P33.00012 Materials considerations for the efficiency of photon-enhanced thermionic emission, JARED SCHWEDE, DANIEL RILEY, KUNAL SAHASRABUDDHE, NICHOLAS MELOSH, ZHI-XUN SHEN, Stanford University — Photon-Enhanced Thermionic Emission (PETE) is a promising method of solar energy conversion that is based on thermal emission of photoexcited electrons from a high-temperature semiconductor, making it attractive for use in tandem with solar thermal systems. Theoretical efficiencies of PETE devices can exceed those of single junction photovoltaics, but experimental tests of the PETE process have displayed low efficiencies.[1] Here we examine this disconnect between experimental results and theoretical promise. We analyze the effects of real semiconductor parameters on the PETE process and relate them to the ultimate performance of a PETE device, directly translating non-idealities of practical materials into constraints on conversion efficiency. The analysis identifies fundamental challenges to efficient conversion based on PETE and establishes design rules that direct the search for semiconductor systems to form the basis of real devices. We also review experimental work guided by these insights that shows increased emission efficiency due to reduced surface recombination, one of the key challenges for realistic solar energy conversion based on PETE.

10:24AM P33.00013 Designing long wavelength barrier based thermophotovoltaic cells, DANTE DEMEO, THOMAS VANDERVELDE, Tufts University Dept. of Electrical and Computer Engineering — This work describes the process of designing low source-temperature thermophotovoltaic cells to harvest energy from thermal sources in the 7-10 micron range. Simulations of the bandstructure are performed for strained layer superlattices (SLS) to act as the p, B, and n regions in a TPV barrier diode. Simulations of the band-alignment of these regions are then performed to ensure a high enough barrier in one band, and a smooth transition in the other. The process is performed iteratively to find an ideal match of specific SLS material and doping concentration in each region. Both conduction band barriers and valence band barriers have been investigated. The balance of system and test apparatuses will also be discussed, as well as preliminary results from samples grown via MBE.

10:36AM P33.00014 Thought waves remotely affect the performance (output voltage) of photoelectric cells, DAYONG CAO, DAQING CAO, Beijing Natural Providence Science & Technology Development Co., Ltd — In our experiments, thought waves have been shown to be capable of changing (affecting) the output voltage of photovoltaic cells located from as far away as 1-3 meters. There are no wires between brain and photoelectric cell and so it is presumed only the thought waves act on the photoelectric cell. In continual rotations, the experiments tested different solar cells, measuring devices and lamps, and the experiments were done in different labs. The first experiment was conducted on Oct 2002. Tests are ongoing. Conclusions and assumptions include: 1) the slow thought wave has the energy of space-time as defined by C1.00007: The mass, energy, space and time systemic theory- MEST. Every process releases a field effect electrical vibration which be transmitted and focussed in particular paths; 2) it has a information of order of tester; 3) the brain (with the physical system of MEST which like a hardware) and consciousness (with the spirit system of the mind, consciousness, emotion and desire-MECD! which like a software) build up a life-informational computer, through some algorithms of DNA and RNA, produce the life-information (include the Genetic code). The Life-Information is a female parent of any information; 4) human can optimize the information. This function is the intelligence; 5) In our experiments, not only thought waves can affect the voltage of the output photoelectric signals by its energy, but they can also selectively increase or decrease those photoelectric currents through remote consciousness interface by a life-information technology.

Wednesday, February 29, 2012 8:00AM - 10:48AM —

Session P34 DCP: Focus Session: Nano III: New Nanoscale Fabrication and Sensing 107A

8:00AM P34.00001 Direct imaging of colloidal nanoparticle growth, structure, and assembly in a transmission electron microscope, PAUL ALIVISATOS, University of California, Berkeley — No abstract available.

8:36AM P34.00002 Computational nanomaterials for novel desalination membrane design: Nanoporous graphene, DAVID COHEN-TANUGI, MIT, JEFFREY C. GROSSMAN, Department of Materials Science & Engineering, MIT — We describe a novel approach for desalination based on nanoporous graphene. Our molecular dynamics calculations show that freestanding graphene patterned with nanometer-sized pores can act as an ultra-thin filtration membrane. Due to size exclusion and chemical interactions with the confining pores, salt ions can be blocked from permeating the membrane at sufficiently small pore diameters. Notably, the pore diameter and the chemical interactions at the water-membrane interface are most important criteria for this system's desalination performance. We will share insights from Molecular Dynamics calculations regarding the theoretical performance of this membrane system and the effects of chemical passivation of the graphene pores on the filtration dynamics. Although the narrow range of acceptable pore sizes suggests that further design innovations will be necessary at the molecular scale before large-scale applications are possible, our existing results predict that pressure requirements for this system can be made roughly competitive with commercial Reverse Osmosis.

8:48AM P34.00003 Structural and electronic properties of bare and capped CdnSen/CdnTen nanoparticles (n = 6, 9), ALEKSEY KUZNETSOV, Department of Chemistry, Duke University, D. BALAMURUGAN, Department of Chemistry, Indiana University, SPIROS S. SKOURTIS, Department of Physics, University of Cyprus, DAVID N. BERATAN, Department of Chemistry, Biochemistry & Physics, Duke University — Relationships between structures and properties (energy gaps, vertical ionization potentials (IP_v), vertical electron affinities (EA_v), and ligand binding energies) in small capped CdSe/CdTe nanoparticles (NPs) are poorly understood. We have performed the first systematic density functional theory study of the structures and electronic properties of Cd_nSe_n/Cd_nTe_n NPs (n = 6, 9), both bare and capped with NH_3^- , SCH_3 , and OPH_3 -ligands. NH_3^- and OPH_3 -ligands cause HOMO/LUMO energy *destabilization* in capped NPs, more pronounced for the LUMOs than for the HOMOs. Orbital destabilization drastically reduces both the IP_v and EA_v of the NPs compared with the bare NPs. For SCH_3 -capped Cd_6X_6 NPs, formation of expanded structures was found to be preferable to crystal-like structures. SCH_3 -groups cause *destabilization* of the HOMOs of the capped NPs and *stabilization* of their LUMOs, which indicates a reduction of the IP_v of the capped NPs compared with the bare NPs. For the Cd_9X_9 NPs, similar trends in stabilization/destabilization of frontier orbitals were observed.

9:00AM P34.00004 New Directions in Plasmonics: Pushing the Space-Time Limit, RICHARD VAN DUYN, Chemistry Department Northwestern University — The lecture will begin with the discussion of our efforts to provide a robust existence proof for SMSERS (Single Molecule Surface Enhanced Raman Spectroscopy). Further, fundamental questions such as: (1) what is the largest possible enhancement factor (EF) and (2) what nanostructure produces the largest EF, will be addressed. Our approach to answering these questions involved the development of new tools such as single nanoparticle SERS and single nanoparticle LSPR spectroscopy spatially correlated with high resolution transmission electron microscopy (HRTEM). Recent results using LSPR biosensors to detect molecular binding events and conformation changes will be presented, including discussions of: (1) pushing the sensitivity of plasmonic biosensors towards the single-molecule detection limit, (2) combining LSPR with complementary molecular identification techniques such as matrix assisted laser desorption/ionization mass spectrometry (MALDI-MS), and (3) the development of new instrumentation for high throughput plasmonic biosensing, and gas sensing with plasmonic nanosensors. Finally, recent developments showing that for the first time, the revolutionary techniques of surface enhanced Raman spectroscopy and femtosecond stimulated Raman spectroscopy (FSRS) can be combined and substantial progress in tip-enhanced Raman spectroscopy (TERS) will be presented. A UHV-TERS instrument has been constructed with atomic resolution of the surface and sub-molecular resolution of the adsorbate, as illustrated with the copper phthalocyanine (CuPc)/Ag(111) system. We can now foresee the day when it will be possible to combine UHV-TERS and surface enhanced FSRS to enable single-molecule spectroscopy with simultaneous nanometer spatial resolution and femtosecond time resolution.

9:36AM P34.00005 Charge Distributions in Polar Semiconductor Nanorods explored with Linear-Scaling DFT Calculations, NICHOLAS HINE, PHILIP AVRAAM, PAUL TANGNEY, PETER HAYNES, Thomas Young Centre, Imperial College London, United Kingdom — Binary polar semiconductors in the wurtzite structure can be grown as nanorods along $\pm[0001]$. In such structures, large dipole moments have been observed. We have studied the distribution of charge in GaAs and ZnO nanorods to elucidate the origin of the dipole moments. To make contact with realistic experiments, rods containing thousands of atoms are simulated using Linear-Scaling DFT calculations with ONETEP [1]. From our calculations we show that both the direction and magnitude of the dipole moment of a nanorod, and its electric field, depend sensitively on how its surfaces are terminated, not on the spontaneous polarization of the underlying lattice. Furthermore, we observe that the Fermi level for an isolated nanorod always coincides with significant density of electronic surface states on its polar surfaces (either mid-gap states or band-edge states). These states pin the Fermi level, and therefore fix the potential difference along the rod. We provide evidence that this effect has a determining influence on the polarity of nanorods, with consequences for the response to changes in surface chemistry, scaling of dipole moment with size, and dependence of polarity on composition.

[1] C. Skylaris et al, JCP 122, 084119 (2005).

9:48AM P34.00006 Reduction of graphene oxide to graphene, A study of changes in the atomic structure¹, A. MITTAL, A. WAGNER, Univ. of Minnesota, C. MATTEVI, Rutgers Univ., A. CHOV, K. LIAO, C. MACOSKO, Univ. of Minnesota, M. CHHOWALLA, Imperial College, K. A. MKHOYAN, Univ. of Minnesota — An economic method for large scale production of graphene is based on exfoliation of graphite into 1-atom thick sheets by oxidation, creating graphene oxide (GO) and subsequent reduction of GO into graphene. Reduced GO sheets approach the highly desired properties of graphene, such as electrical conductivity and mechanical strength, to various degrees, but not completely. To understand why, we must understand the nanostructure of the sheets. Different methods of reduction result in products that are similar to graphene, but these products retain some oxidized areas or contain regions with sp^3 bonded carbon. The concentration and distribution of these defects on the reduced GO sheet affect the properties of the 2D material. Here, we have characterized the atomic structure of GO and reduced GO via high resolution transmission electron microscopy, electron diffraction, and electron energy loss spectroscopy. Spectroscopic data taken during thermal reduction of GO shows changes in the fine structure of carbon K-edge as the carbon changes from an oxidized form to elemental amorphous carbon to graphite like form, clearly delineating the process of reduction of GO to graphene. Products of several other reduction methods are also characterized revealing information on electronic environment surrounding carbon atoms, distribution of crystalline areas, and oxygen removal from GO.

¹Support from NSF, ADMIRE, and UMN Characterization Facility.

10:00AM P34.00007 Atomic-scale mapping of cerium valence in ceria-zirconia-supported Pd model planar catalysts¹, SHUYI ZHANG, MICHAEL KATZ, KAI SUN, University of Michigan, OBIEFUNE EZEKOYE, McKinsey & Company, MANJULA NANDASIRI, Pacific Northwest National Laboratory, HUNGWEN JEN, Ford Motor Company, GEORGE GRAHAM, XIAOQING PAN, University of Michigan, UNIVERSITY OF MICHIGAN TEAM, PACIFIC NORTHWEST NATIONAL LABORATORY COLLABORATION, FORD MOTOR COMPANY COLLABORATION — Cerium-based oxides have long been regarded as an important class of catalyst support materials. It is also recognized that the interaction between precious metal and ceria-based support material enhances the reducibility of the ceria. The combination of scanning transmission electron microscopy (STEM) and electron energy loss spectroscopy (EELS) can provide an atomic-scale picture of the interaction between precious metal particles and their support material. In our work, aberration corrected STEM-EELS is used to study the valence of cerium in the vicinity of palladium nanoparticles supported on a ceria-zirconia (CZO) thin film. A monolayer-equivalent of Pd was deposited onto a 50nm-thick CZO thin film, which was then subjected to different thermal treatments. The EELS spectra extracted from the top several atomic layers of the CZO film exhibit typical 3+ character following a low-temperature reduction treatment, indicating the formation of oxygen vacancies. A variety of control experiments have also been performed to exclude possible artifacts caused by electron beam irradiation.

¹DMR-0907191, CBET- 0933239, and DMR-0723032

10:12AM P34.00008 Correlated Percolation Model of Graphene Hydrogenation, ALEJANDRO SUAREZ, Department of Physics, Penn State University, TYLER MAUNU, School of Physics & Astronomy, University of Minnesota, JORGE O. SOFO, Department of Physics, Penn State University — Hydrogenation of graphene by exposure to an atomic hydrogen plasma is a random process. However, the presence of hydrogen already attached to the plane increases the sticking probability of incoming adatoms. We simulate this process as a correlated percolation model where the hydrogen occupation probability of a carbon site is increased or decreased depending on the hydrogenation of the nearest neighboring carbon atoms. This enhancement modifies the cluster distribution on the surface and consequently the electronic structure of the system. We study these effects with a tight binding model and find that, although the density of states at the Fermi level is greatly increased by hydrogenation, the inverse participation ratio shows that not all of these states will contribute to conduction. In fact, for hydrogenation levels of greater than 40% of the lattice, localized states begin to dominate at the Fermi level. A realistic set of values for the sticking probabilities is determined by analysis of the STM images of this system. Through the modeling of this mesoscopic process, we gain a better understanding of how chemically modified graphene is produced and what its transport properties are.

10:24AM P34.00009 Effect of charged impurities and morphology on oxidation reactivity of graphene, MAHITO YAMAMOTO, WILLIAM CULLEN, THEODORE EINSTEIN, MICHAEL FUHRER, Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742-4111 — Chemical reactivity of single layer graphene supported on a substrate is observed to be enhanced over thicker graphene. Possible mechanisms for the enhancement are Fermi level fluctuations due to ionized impurities on the substrate, and structural deformation of graphene induced by coupling to the substrate geometry. Here, we study the substrate-dependent oxidation reactivity of graphene, employing various substrates such as SiO₂, mica, SiO₂ nanoparticle thin film, and hexagonal boron nitride, which exhibit different charged impurity concentrations and surface roughness. Graphene is prepared on each substrate via mechanical exfoliation and oxidized in Ar/O₂ mixture at temperatures from 400-600 °C. After oxidation, the Raman spectrum of graphene is measured, and the Raman D to G peak ratio is used to quantify the density of point defects introduced by oxidation. We will discuss the correlations among the defect density in oxidized graphene, substrate charge inhomogeneity, substrate corrugations, and graphene layer thickness. This work has been supported by the University of Maryland NSF-MRSEC under Grant No. DMR 05-20471 with supplemental funding from NRI, and NSF-DMR 08-04976.

10:36AM P34.00010 Numerical Study of Carrier Multiplication in Nanocrystalline form of PbSe and PbS and the bulk, ANDREI PIRYATINSKI, KIRILL VELIZHANIN, Theoretical Division, Los Alamos National Lab — Using previously developed Exciton Scattering Model, we report on systematic numerical study of the carrier multiplication (CM) dynamics in spherically symmetric PbSe and PbS nanocrystals (NCs) and bulk. The quantum efficiency (QE) associated with the photogeneration and population relaxation processes are calculated. It is found that the photogeneration event provides small, about 5%, contribution to the total QE compared to the contribution from the population relaxation process. The analysis shows that the impact ionization dynamics is the main mechanism responsible for the CM during *both* the photogeneration and the population relaxation events. Furthermore, the calculated photogeneration and total QEs for various size NCs are found never to exceed the calculated limiting values for bulk. This observation is explained in terms of the quantum-confinement induced weak effective Coulomb enhancement whose contribution to the impact ionization rate is fully suppressed by the reduction in the biexciton density of states. We also find weak dependence of the total QE on the transform limited pump pulse duration. Comparison of the calculated QEs to published experimental data shows that our calculations well reproduce the experimentally observed trends.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P35 DCP: Focus Session: DFT V: Partitioning and Embedding Theories; Finite-Temperature 107B

8:00AM P35.00001 Exactly Embedded Density Functional Theory for Modeling Chemical Reactions, THOMAS MILLER, California Institute of Technology — We will describe embedded density functional theory methods for performing accurate and scalable electronic structure theory calculations in large molecular systems [1,2], with application to clusters, liquids, and electrode interfaces.

[1] Goodpaster JD, Ananth N, Manby FR, and Miller TF, J. Chem. Phys., 133 (2010) 084103.

[2] Goodpaster JD, Barnes TA, and Miller TF, J. Chem. Phys., 134 (2011) 164108.

8:36AM P35.00002 Exactly embedded DFT for the efficient simulation of large systems, TAYLOR BARNES, JASON GOODPASTER, THOMAS MILLER, California Institute of Technology — Although standard wavefunction-based approaches to electronic structure problems have experienced great success in the study of small systems, their poor size scaling prohibits their application to larger systems. One promising technique for overcoming this scaling problem is embedded Density Functional Theory (e-DFT), in which a large system is divided into many smaller subsystems, with individual wavefunction-based calculations being performed on each subsystem. Using our newly developed Exactly Embedded (EE) technique, we demonstrate highly accurate e-DFT calculations on aqueous systems consisting of hundreds of atoms. Furthermore, these calculations are shown to exhibit excellent size scaling and to be massively parallelizable, allowing for efficient calculations of condensed-phase systems.

8:48AM P35.00003 A unified quantum mechanics embedding theory for materials and molecules¹, CHEN HUANG, Department of Physics, Princeton University, Princeton, New Jersey 08544, USA, MICHELE PAVONE, EMILY CARTER², Department of Mechanical and Aerospace Engineering, Princeton University, Princeton, New Jersey 08544-5263, USA — It is essentially impossible to apply highly accurate quantum mechanics methods to large material samples, creating a need for a sophisticated embedding theory that can locally refine the accuracy of predicted properties. Here, we present a new ab-initio embedding theory that can treat different regions in the material with quantum mechanics methods of appropriately varying levels of accuracy in a seamless way. We first remove the non-uniqueness of embedding potential definitions that exists in most previous embedding theories by introducing a physical constraint that all regions share a common embedding (interaction) potential. We then introduce a key step to achieve seamless embedding: reformulating the system's total energy solely in terms of the embedding potential, i.e., we construct a potential-functional embedding theory (PFET). We demonstrate how to efficiently solve PFET for molecules and materials and give an outlook for how to perform seamless "multi-physics" material simulations with PFET.

9:00AM P35.00004 Multi-level partitioning using embedded density functional theory, JASON GOODPASTER, TAYLOR BARNES, THOMAS MILLER, California Institute of Technology — Embedded density functional theory (e-DFT) methods are typically limited to the description of weakly interacting systems, because an exact form of the kinetic energy (KE) density functional is unknown. We have developed a method that avoids approximations to the KE functional and provides a formally exact approach to performing electronic structure calculations in the e-DFT framework. This framework allows systems to be divided into smaller subsystems which can be treated at different levels of theory with the inter-subsystem potential calculated using our e-DFT protocol. Therefore, in regions of large systems where DFT is known to perform poorly, such as van der Waals interactions and strongly correlated electrons, wavefunction calculations can be used. We discuss density partitioning strategies for embedded density functional theory and the accuracy of this multi-level method.

9:12AM P35.00005 Partition Density Functional Theory, ADAM WASSERMAN, Purdue University — Partition Density Functional Theory (PDFT) is a formally exact method for obtaining molecular properties from self-consistent calculations on isolated fragments [1,2]. For a given choice of fragmentation, PDFT outputs the (in principle exact) molecular energy and density, as well as fragment densities that sum to the correct molecular density. I describe our progress understanding the behavior of the fragment energies as a function of fragment occupations, derivative discontinuities, practical implementation, and applications of PDFT to small molecules. I also discuss implications for ground-state Density Functional Theory, such as the promise of PDFT to circumvent the delocalization error of approximate density functionals.

9:48AM P35.00006 Finding Partition Potentials, JONATHAN NAFZIGER, Department of Physics, Purdue University, MORREL COHEN, Department of Physics and Astronomy, Rutgers University and Department of Chemistry, Princeton University, ADAM WASSERMAN, Department of Chemistry, Purdue University — Partition Density Functional Theory is a formally exact approach to partitioning molecules into fragments via functional minimization and constraints on fragment densities. Cohen and Car proposed a Dynamical Optimization Algorithm for Partition Theory inspired by the Car-Parrinello Method of electronic structure [1]. We modify this algorithm to incorporate a reference HOMO wave-function calculation as a guide to obtain the partition potential, a global quantity arising as the Lagrange multiplier that guarantees satisfaction of the density constraint. We report on the implementation of this procedure for one-dimensional systems, and possible implications for linear-scaling electronic-structure calculations.

10:00AM P35.00007 Temperature dependence of Thomas-Fermi errors¹, AURORA PRIBRAM-JONES, Department of Chemistry, University of California, Irvine, KIERON BURKE, Departments of Physics and Chemistry, University of California, Irvine — Finite temperature Thomas-Fermi theory, in addition to its success in systems dominated by classical behavior, can also form the basis for development of a finite temperature local density approximation and its leading corrections. It is therefore imperative that we fully understand its limitations and strengths. To this end, the temperature dependence of Thomas-Fermi errors in densities and integrated quantities for simple models is explored. Behavior of finite-temperature Thomas-Fermi theory in limiting cases will be discussed in the contexts of traditional DFT and its semiclassical foundations. Analysis of finite temperature Thomas-Fermi as a potential functional will be presented.

10:24AM P35.00009 Systematic Results in Finite Temperature DFT¹, TAMAS GAL, JAMES DUFTY, Department of Physics, University of Florida — An exact representation for the non-interacting free energy density functional is identified from the thermodynamics of a non-uniform, finite temperature system of particles in an external potential. A formally exact functional density expansion whose leading term is the Thomas-Fermi approximation is described to second order in the density non-uniformity. The familiar Perrot form [Phys. Rev. A 20, 586 (1979)] is recovered from a subsequent smooth gradient expansion. A related formal expansion about the Thomas-Fermi plus von Weizsacker functional to second order is also described and discussed.

¹Work supported under US DOE Grant DE-SC0002139.

10:36AM P35.00010 Finite Temperature Scaling of the Free Energy Density Functional¹, JAMES DUFTY, VALENTINE KARASIEV, SAMUEL TRICKEY, Department of Physics, University of Florida — Recently, we reported exact scaling relations and related bounds and inequalities for the non-interacting ("Kohn-Sham") free-energy density functional [Phys. Rev. B 84, 125118 (2011)]. Here we extend the analysis to obtain similar results for the full, interacting functional. The extension is obtained by dimensionless analysis for the case of v -representable densities. Connection with the corresponding ground-state scaling is made.

¹Work supported under US DOE Grant DE-SC0002139.

10:48AM P35.00011 Construction of Generalized Gradient Approximation Free Energy Density Functionals¹, SAM TRICKEY, VALENTIN KARASIEV, TRAVIS SJOSTROM, QTP, Physics and Chemistry, U. Florida — By analysis of the second-order gradient approximation (SGA) for the non-interacting electron free energy density, we propose a finite-temperature generalized gradient approximation (ftGGA) for the noninteracting free energy density (both kinetic and entropic contributions). By analogy we also introduce a ftGGA for the exchange free energy density functional. We have implemented the finite-temperature Thomas-Fermi (ftTF), SGA, and a new finite-temperature GGA free-energy functional in the orbital-free density functional theory (OFDFT) code PROFESS. We compare self-consistent OFDFT results with standard Kohn-Sham data. The local pseudopotentials used in the OFDFT calculations are validated by comparison between Kohn-Sham results obtained with standard non-local pseudopotentials and with the same local pseudopotentials.

Wednesday, February 29, 2012 8:00AM - 11:00AM —
Session P36 DCP: Focus Session: Environment III: Nanoparticles, Surfaces and Catalysis 107C

8:00AM P36.00001 Nanominerals, Mineral Nanoparticles, and Earth Processes: Details on How Nanoparticles Work in the Environment, MICHAEL HOHELLA, Virginia Polytechnic Institute and State University — Naturally occurring inorganic nanoparticles have been one of the principal catalytic components of Earth throughout its history. Yet these ubiquitous materials have largely escaped our close scrutiny until very recently. They are illusive and difficult to study. They have properties that change significantly with their exact size, shape, aggregation state, and surrounding environment. In the past, it has not even been clear how they accumulate, disperse, and move around the planet, nor even for sure what their major sources and sinks are. We have now compiled and derived a global budget for naturally occurring inorganic nanoparticles, including an assessment of their sources and sinks, as well as their fluxes between various Earth compartments (atmosphere, continents, continental shelves, and open oceans). In addition, these kinds of budgets provide a basis for fundamental understanding such as residence and transfer times between compartments. Specific findings include the following: 1) The primary producer of Earth's inorganic nanoparticles is soil through terrestrial weathering processes; 2) rivers, and to a lesser extent glaciers, bring 0.1% to 0.01% of the Earth's continental nanomaterial reservoir to the continental edge/ocean margins each year; 3) only about 1.5% of this material makes it to the deep oceans due to aggregation and settling in saline ocean margins; and 4) the airborne and waterborne inputs of nanominerals and mineral nanoparticles to the open oceans are very similar. These kinds of results, along with a much better understanding of the characteristics of naturally occurring inorganic nanoparticles via direct observation in the field coupled with laboratory studies, provide a useful foundation upon which to predict the behavior and fate of manufactured nanoparticles, many of which are very similar to naturally occurring varieties. Even when specific correlations between naturally occurring and manufactured nanoparticles cannot be made, important clues in manufactured nanoparticle behavior in complex environments can be obtained by observing natural systems.

8:36AM P36.00002 Surface Reactivity of Core Shell Iron-Iron Oxide Nanoclusters towards Breakdown of Carbon Tetrachloride, MANINDER K. TARSEM S., YOU QIANG, Department of Physics, University of Idaho, Moscow, ID 83844, HONGSEOK KIM, Pusan National University, Korea, 609-735, JAMES E. AMONETTE, DONALD R. BAER, Pacific Northwest National Laboratory, Richland, WA 99352 — Zero-valent iron (ZVI) is one of the technologies for groundwater remediation to reduce contaminants by removal of mobile chlorinated hydrocarbons. Iron-Iron oxide ($\text{Fe}/\text{Fe}_3\text{O}_4$) nanoclusters (NCs) made in our laboratory using cluster deposition technique have enhanced reactivity towards targeted contaminants due to the presence of ZVI protected by a passivated oxide shell. Here, we investigate the effectiveness of the $\text{Fe}/\text{Fe}_3\text{O}_4$ NCs in reducing carbon tetrachloride (CT) under laboratory conditions. The reactivity of the NCs was investigated by conducting unbuffered aqueous batch experiments to reduce CT at room temperature. Initial results show that 80% of the degradation of CT resulted in the formation of dichloromethane (DCM) and chloroform (CF); the remainder likely followed a competing pathway to yield nonhazardous products such as CO. The production of undesirable hydrogenated products such as DCM and CF suggests that the dominant reaction pathway occurs through hydrogen (H) atom transfer via H atoms generated by corrosion of the iron. Comparative experiments with ZVI NCs prepared by other methods are underway and the results will be reported. Future work is to analyze and understand factors that control the reaction pathways between desirable and undesirable products.

8:48AM P36.00003 Environmental Catalysis at the Boundary between Metals and Metal Oxides, WILLIAM F. SCHNEIDER, University of Notre Dame — Growing theoretical and computational evidence points to the participation of partially to completely oxidized catalyst surfaces during catalytic oxidations under realistic conditions. These catalytic oxidations are of both fundamental scientific interest and of practical importance in a variety of contexts, including in particular environmental NO_x remediation, yet fundamental understanding of the coupling between surface structure and composition, reactive environment, particle size, and catalytic reactivity is still in its infancy. In this work we use density functional theory (DFT) models to consider the coupling between catalytic oxidation activity and the transformation of metal to oxide surface, taking as our model CO and NO oxidation on oxygen-covered to oxidized Pt surfaces. We describe DFT-parameterized cluster expansions (CEs) of O on Pt that capture the transition from metal to oxide, spectroscopic signatures of these transformations, and the incorporation of the metal-to-oxide transition into kinetic models of surface reactivity.

9:24AM P36.00004 Effect of substrate-catalyst interaction on Spin-dependent chemical reactions: CO oxidation¹, SHUNFANG LI, Department of Materials Science and Engineering, University of Tennessee; School of Physics, Zhengzhou University, China, YANFEI GAO, Department of Materials Science and Engineering, University of Tennessee; Materials Science and Technology Division, ORNL, ZHENYU ZHANG, Department of Physics and Astronomy, University of Tennessee; ICQD, University of Science and Technology of China, Hefei, Anhui, China — First-principles calculations have been performed to investigate and compare the catalytic reactivity of $\text{Ni}(\text{Pd})_1/\text{TiO}_2(110)$ and $\text{Ni}(\text{Pd})_2/\text{TiO}_2$, for CO oxidation. A recent experiment showed that the catalysis of small $\text{Ni}(\text{Pd})_2$ clusters deposited on rutile $\text{TiO}_2(110)$ surface exhibit very different performance for CO oxidation, compared with the single atom cases, $\text{Ni}(\text{Pd})/\text{TiO}_2(110)$. However, the underlying mechanism of this interesting phenomenon is still unclear. Our calculations show that the catalyst-substrate interaction plays a key role in both the thermodynamic and kinetic process of the catalytic reactions. Particularly, the spin degree of freedom of the complex oxide is found to dominate the reaction rate. Essentially, the oxidation of CO on the single atom cases is a spin-forbidden reaction, while it is spin-permitting for the dimer cases. This work provides valuable guidance for high efficient catalyst design at the atomic scale.

9:36AM P36.00005 Assessing Actinide-Oxygen Covalency by K-edge X-ray Absorption Spectroscopy. , DAVID SHUH, Chemical Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — The development of many essential nuclear technologies requires a comprehensive grasp of the electronic ground and valence states of molecular actinide bonding interactions. Identifying itinerant or delocalized electrons – in molecular nomenclature, ionic or covalent bonds – is a longstanding problem in actinide science. Recent advances have shown that the transition intensities measured by ligand K-edge X-ray absorption spectroscopy (XAS) directly relate to coefficients of covalent orbital mixing. Ligand K-edge XAS has been employed successfully to describe the valence states of materials containing predominantly ionic metal–Cl and metal–S bonds, however, it remains experimentally challenging to obtain quantitative intensity information at the K-edge for light atoms such as C, O, N, and F. Insights regarding the nature and extent of orbital mixing in actinide–O bonds are now within reach through a combination of XAS with a scanning transmission X-ray microscope (STXM) and hybrid density functional theory calculations (DFT). A new effort to employ these techniques for non-conducting molecular systems containing interactions between actinide and oxygen-based ligands will be discussed. Oxygen K-edge XAS measurements and DFT for a series of six structurally related transition metal oxides suggest that metal nd and O 2p orbital mixing increases with increasing Z. The actinyl ions were chosen for the first O K-edge XAS measurements with actinides because they represent the most important high-valent actinide species in the environment. Features in the polarized XAS of the actinyls follow anticipated trends based on the 5f and 6d orbital energies and occupancies. Results from an ongoing collaboration with theorists ties these experimental trends in actinide–O orbital mixing to changes in 3d, 4d, 5d, and 6d/5f valence orbital occupancies.

10:12AM P36.00006 Submonolayers of Au/Pd on the hematite (0001) and magnetite (111) surfaces¹ , ADAM KIEJNA, TOMASZ PABISIAK, TOMASZ OSSOWSKI, Institute of Experimental Physics, University of Wrocław, Poland — Ultra-thin films and nanostructures formed by noble metals on oxide surfaces exhibit enhanced catalytic activity for CO oxidation. We used the spin-polarized density functional theory (DFT) and the DFT+U method, accounting for the strong on-site Coulomb correlations, to study the submonolayer adsorption of Au/Pd atoms on two stable iron-oxide surfaces: hematite (0001) and a magnetite (111). For each surface, adsorption on two terminations has been studied: one terminated with iron and the other with oxygen. Both Au and Pd bind strongly to hematite and magnetite surfaces and induce large changes in their geometry. DFT and DFT+U provide qualitatively similar surface geometries but they differ much in the prediction of the surface energetics and the electronic and magnetic properties of the oxides. Pd binds stronger than Au both to hematite and magnetite surfaces and the Au/Pd bonding to the O-terminated surface is distinctly stronger than that to the Fe-terminated one. For hematite, the DFT+U bonding is by 0.3–0.6 eV weaker than DFT on the Fe-terminated surface and about 2 eV stronger on the O-terminated one. For magnetite, in each case, DFT+U gives stronger bonding than DFT. The differences between DFT and DFT+U results are discussed based on the calculated electronic structure.

10:24AM P36.00007 ABSTRACT WITHDRAWN —

Wednesday, February 29, 2012 8:00AM - 11:00AM —
Session P37 DCMP: CDW Materials - Chalcogenides and other 108

8:00AM P37.00001 Temperature- and pressure-dependent Raman scattering study of phase transitions in ZrTe_3 ¹ , S. GLEASON, S. YUAN, T. BYRUM, S.L. COOPER, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801, C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973 — Pressure-induced superconductivity has been discovered in many classes of materials, such as the iron pnictides and transition metal chalcogenides. ZrTe_3 is a representative member of the latter whose ground state can be tuned between charge density wave and superconducting phases via pressure or intercalation. Microscopic information about the structural evolution of ZrTe_3 in response to applied pressure is lacking at present. In this talk, we describe a temperature- and pressure-dependent Raman scattering study of the structural evolution of ZrTe_3 through its temperature- and pressure-dependent phase transitions.

¹Work supported by the U.S. Department of Energy under Award No. DE-FG02-07ER46453. T.B. supported by an NSF Graduate Fellowship.

8:12AM P37.00002 Ultrafast Dynamics of a Charge Density Wave via Time-Resolved Resonant Diffraction , R.G. MOORE¹, SLAC National Accelerator Laboratory — Understanding the emergence of collective behavior in correlated electron systems remains at the forefront of modern condensed matter physics. The key to such an understanding is unraveling the contributions from the coupling degrees of freedom in exotic many body states. Density waves, both of charge and spin, have been studied for decades and a wealth of information and insight has been gained. However, there are still open questions that need to be solved for a complete description of the phenomena as there are several existing density wave systems that exhibit prototypical behavior while violating traditional theory. Ultrafast dynamics of such a system, TbTe_3 , has been investigated via time-resolved resonant diffraction at the SXR endstation at LCLS. Oscillations of the amplitude mode and coherent phonons have been observed previously in time resolved photoemission and reflectivity measurement but, here we reveal a direct observation of the lattice response via resonant diffraction. Watching dynamics of the two dimensional Te plane density wave diffraction peak at a resonant energy of a bystander Tb atom reveals new insights into the coupling responsible for the formation of the state. Results and comparison with previous time resolved measurements will be discussed.

¹This work represents the efforts of more than 20 authors who will be acknowledged during the presentation.

8:24AM P37.00003 Experimental Observation of Chiral Order in TiSe_2 ¹ , RAYMOND OSBORN, JOHN-PAUL CASTELLAN, STEPHAN ROSENKRANZ, JASPER VAN WEZEL, JACOB RUFF, UTPAL CHATTERJEE, Argonne National Laboratory, GORAN KARAPETROV, Drexel University — Recent STM measurements on TiSe_2 were interpreted as evidence of chirality in the charge-density-wave order parameter, i.e., a rotation in the phase of the three in-plane components of the CDW order from one layer to the next. Recently, J. van Wezel has shown theoretically how a chiral state can arise from the onset of orbital order of the Ti 3d and Se 4p states in conjunction with the charge order at a temperature at or below the CDW transition temperature [arXiv:1106.1930v1 (2011)]. This theory predicts a lowering of the symmetry of the ordered phase from $P3c1$ to $P2$. We present the results of synchrotron x-ray diffraction measurements on a single crystal of TiSe_2 that provide evidence of a second structural phase transition 15K below the CDW transition, consistent with the proposed space group.

¹Supported by U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under contract No. DE-AC02-06CH11357.

8:36AM P37.00004 Pressure-induced CDW suppression in 1T-TiSe₂¹, YOUNG IL JOE, University of Illinois, K. FINKELSTEIN, CHESS, S. YUAN, S.L. COOPER, PETER ABBAMONTE, University of Illinois — 1T-TiSe₂ is a prototypical transition-metal dichalcogenide showing a commensurate CDW phase transition. It has been shown that hydrostatic pressure suppresses the CDW order and induces superconductivity. Here we present a high-pressure x-ray scattering study of the CDW order parameter and its fluctuations in TiSe₂. The integrated intensity at the base temperature as a function of pressure shows a positive curvature, indicating deviation from mean-field behavior. The ratio between the lattice distortion and the critical temperature is pressure-dependent, indicating a cross-over from strong to weak coupling limits. Using a Monte Carlo simulation of the three-component Potts model, we argue that the amount of anisotropy and the effective dimension must be taken into account to explain the properties of the phase transition.

¹This work was supported by DOE grant DE-FG02-07ER46453

8:48AM P37.00005 Chiral charge and orbital order in 1T-TiSe₂¹, JASPER VAN WEZEL, Argonne National Laboratory — Helical arrangements of spins are common among magnetic materials. The first material to harbor a corkscrew pattern of charge density on the other hand, was discovered only very recently [1,2]. The nature of the order parameter is of key relevance, since rotating a magnetic vector around any propagation vector trivially yields a helical pattern. In contrast, the purely scalar charge density cannot straightforwardly support a chiral state. Here we resolve this paradox by identifying the microscopic mechanism underlying the formation of the chiral charge density wave in 1T-TiSe₂. It is shown that the emergence of chirality is accompanied by the simultaneous formation of orbital order [3]. We show that this type of combined orbital and charge order may in fact be expected to be a generic property of a broad class of charge ordered materials and discuss the prerequisites for finding chiral charge order in other materials.

9:00AM P37.00006 Evolution of the Charge Density Wave state in Cu_xTiSe₂¹, MARIA IAVARONE, ROBERTO DI CAPUA², XIN ZHANG, MARYAM GOLALIKHANI, STEVEN MOORE, Physics Department, Temple University, Philadelphia, PA 19122, USA, GORAN KARAPETROV, Physics Department, Drexel University, Philadelphia PA 19104, USA — 1T-TiSe₂ is a quasi two-dimensional CDW material showing a 2x2x2 superlattice modulation below 200 K. Upon Cu doping the CDW is suppressed and superconductivity is induced. We present scanning tunneling microscopy and spectroscopy measurements of the charge-density wave state in 1T-TiSe₂, Cu_{0.05}TiSe₂ and Cu_{0.06}TiSe₂ single crystals. Topography images at 4.2 K reveal that the charge density waves are present in all samples studied, although the amplitude of the charge modulation decreases with the Cu-doping. Moreover, the chiral phase of the charge density wave is preserved also in Cu-doped samples. Tunneling spectroscopy shows that there is only a partial gap in the pure compound, with bands crossing the Fermi surface. In the Cu-doped samples the system becomes more metallic due to the increase of the chemical potential.

9:12AM P37.00007 Effect of dimensionality on charge density wave instabilities in TaS₂ and TaSe₂, YIZHI GE, AMY Y. LIU, Physics Department, Georgetown University — Recent successes in making exfoliated single-layer transition-metal dichalcogenides has brought new interest to these materials, particularly with respect to the effects of dimensionality. As layered bulk materials, the 1T and 2H polymorphs of TaS₂ and TaSe₂ undergo a number of charge-density-wave (CDW) transitions. However, recent experiments have found that the CDW instability does not survive in nanopatches of 2H-TaS₂. Here we present a density-functional theory investigation of the CDW instability in single- and few-layer TaS₂ and TaSe₂, focusing on the role of the interlayer interactions. The effects of dimensionality on structure, electronic structure, and electronic-phonon coupling will be discussed.

9:24AM P37.00008 Disorder Induced Melting of Charge Density Wave Order in doped 2H-NbSe₂ systems, UTPAL CHATTERJEE, STEPHAN ROSENKRANZ, JOHN CASTELLAN, JASPER VAN WEZEL, RAY OSBORN, Argonne National Laboratory, MARIA IAVARONE, Temple University, GORAN KARAPETROV, Drexel University — Using a combination of Angle Resolved Photoemission Spectroscopy (ARPES), X-ray diffraction, transport and Scanning Tunneling Microscopy (STM) measurements on pristine as well as disordered 2H-NbSe₂ samples, we have found that the onset Temperature T_{cdw} for Long Ranged Charge Density Wave (CDW) order gets quickly suppressed with concentration of disorder ions (X) and at certain critical concentration (X_c) it undergoes a quantum melting. Our STM measurements provide the evidence for local CDW ordering in doped samples for temperatures way above T_{cdw}. On the other hand, our ARPES measurements have found evidences for the presence of energy gap for both T > T_{cdw} & X > X_c. We argue, all these experimental observations from completely different probes hint towards phase fluctuations of the order parameter as the mechanism behind the destruction of CDW order in quasi 2-d systems, such as 2H-NbSe₂.

9:36AM P37.00009 Spectroscopic imaging of the charge density wave in 2H-NbSe₂¹, ANJAN SOUMYANARAYANAN, Massachusetts Institute of Technology, MICHAEL M. YEE, YANG HE, Harvard University, DIRK RAHN, KAI ROSSNAGEL, Kiel University, ERIC W. HUDSON, Pennsylvania State University, JENNIFER E. HOFFMAN, Harvard University — Transition metal dichalcogenides are an ideal playground to study the interplay between charge density waves (CDWs) and superconductivity. We perform atomically resolved scanning tunneling microscopy and spectroscopy at cryogenic temperatures on the chalcogenide polytype 2H-NbSe₂ to study the energy, temperature and spatial dependence of the CDW. By comparing our results with a tight-binding model, we disentangle the spectral behavior of the CDW phase in the material.

9:48AM P37.00010 Strong Periodic Lattice Distortion in Transition Metal Dichalcogenides, JIXIA DAI, EDUARDO CALLEJA, YUE CAO, DANIEL DESSAU, KYLE MCELROY, Department of Physics, University of Colorado at Boulder, Boulder, Colorado 80309, USA, HELMUTH BERGER, Department de Physique, EPF Lausanne, CH-1015 Lausanne, Switzerland, XIANGDE ZHU, LIJUN LI, YUPING SUN, Key Laboratory of Materials Physics, Institute of Solid State Physics, CAS, Hefei 230031, China, T. WOLF, Karlsruher Institut für Technologie, Institut für Festkörperphysik, P.O.B. 3640, D-76021 Karlsruhe, Germany — The charge density wave (CDW) instability was initially proposed to be the result of the Peierls mechanism in which a divergence in electronic response function results in a periodic charge redistribution; i.e. the electron gas itself is unstable with respect to the formation of a periodically varying electron charge density. However, the mechanism of CDW in many 2D Transition Metal Dichalcogenide (TMD) is still under debate. Fermi surface nesting was originally believed to act as the driving mechanism of CDW transitions in these materials; however, recent reports from both theoretical and experimental studies are not quite within this simple model. We use Spectroscopic Imaging Scanning Tunneling Microscope (SI-STM) to study the surfaces of 2H-TaSe₂, 2H-TaS₂, and 2H-NbSe₂ at various temperatures from 6K to above 100K. Topographic images and differential conductance data were recorded and analyzed in order to help understanding the underlying physics of CDW phases. Our results shows that Periodic Lattice Distortion (PLD) likely plays a more important role than the charge modulation in 2D TMD.

10:00AM P37.00011 Low frequency resistance fluctuations in nanoribbons of charge density wave (CDW) conductor NbSe₃, ZHENZHONG SHI, ADAM STABILE, Department of Physics, PETER MARLEY, Department of Chemistry, SUJAY SINGH, Department of Physics, SARBAJIT BANERJEE, Department of Chemistry, GANAPATHY SAMBANDAMURTHY, Department of Physics, University at Buffalo, Buffalo, NY 14260. — We investigate finite size effects in the low-frequency ($1 \text{ mHz} < f < 10 \text{ Hz}$) resistance fluctuations of individual nanoribbons of single-crystalline NbSe₃ (cross sections of 10^4 nm^2) across the two CDW transitions ($\sim 59 \text{ K}$ and $\sim 141 \text{ K}$). This ultra sensitive frequency-dependent study of the electrical noise is crucial in improving our understanding of the mechanisms that generate noise around CDW transitions. The power spectral density, S_R , of the resistance noise has a generic form, $S_R \sim 1/f^\alpha$, typical of a diffusive metallic conductor. Below the CDW transition at 59 K , where the CDW is pinned by disorder, S_R (at 1 Hz) shows a non-monotonic behavior with a maximum magnitude around 45 K . A similar peak in S_R is also observed at 125 K , below the second CDW transition. Also, it is well known that the CDW state can be depinned by an application of a high bias voltage or current and S_R is measured as a function of current across the pinning-depinning of CDW. S_R shows a complex, non-monotonic dependence and is extremely sensitive to temperature below the CDW transition. In contrast, S_R is bias independent above the CDW transitions as expected from a metal. The implications of these noise behaviors in understanding the pinning and depinning of CDW in NbSe₃ will be discussed.

10:12AM P37.00012 Extrinsic control of collective transport in quasi-1D materials with end contacts geometry¹, A.F. ISAKOVIC, A. BELKADI, Khalifa University - KUSTAR, Abu Dhabi, UAE, K. EVANS-LUTTERODT, BNL-NSLS, NY, USA — End contacts to mesowires of NbSe₃ and TaS₃ were nanofabricated and tested with transport, noise and X-ray microdiffraction measurements. We measured unusual and unexpected weak dependence of collective current on temperature in the $[70\text{K}, 90\text{K}]$ range, close to $2/3T_{P1}$ point, indicating a modification of CDW condensate transport due to the end contact geometry. This is accompanied with modifications to the temperature dependence of the phase slip voltage. We also report a partial control of the threshold field (E_T) for CDW sliding, below T_{P2} , with the decrease in E_T by as much as one order of magnitude in a limited temperature range below $2/3T_{P2}$. These changes can be also seen in electric field modified X-ray topography images performed with sub-micron focused synchrotron X-rays (X13B beamline at NSLS). The most likely causes of these phenomena when end contacts are applied, are in modifications of: (a) carrier injection efficiency and, (b) the phase loop formation mechanism.

¹The work at BNL-NSLS was supported by US DOE, contract DE-AC02-98CH10886; the sample growth was done in Prof. R. E. Thorne laboratory at Cornell University. A.B. and A.F.I. also acknowledge recent support from ATIC-SRC (2011-KJ-2190) and KUSTAR.

10:24AM P37.00013 Spectroscopic evidence of the Peierls transition in three-dimensional charge density wave solids, BARBARA MANSART, MATHIEU COTTET, THOMAS J. PENFOLD, Ecole Polytechnique Federale de Lausanne, STEPHEN B. DUGDALE, University of Bristol, RICCARDO TEDIOSI, universite de Geneve, MAJED CHERGUI, FABRIZIO CARBONE, Ecole Polytechnique Federale de Lausanne — We studied the ultrafast photoinduced charge-density-wave to metal phase transition in a complex solid, namely Lu₅Ir₄Si₁₀. After melting the charge ordering using infrared laser pulses, the consequent charge redistribution is probed with fs time resolution through the spectral weight analysis of the transient optical response over a broad energy range. The time-dependent spectral weight reveals a signature of the CDW melting and the time-scale of this photo-induced phase transition. This new kind of analysis allows us to show that the charge order remains preserved until the lattice distorts sufficiently to induce the phase transition. These results are completed by ab-initio modeling of the electronic band structure, identifying the orbitals involved in the CDW and the electronic transitions leading to the photo-induced melting of the charge order. This allows us to reveal the Peierls origin of multiple CDW in this three-dimensional solid.

10:36AM P37.00014 Gapped sliding phononic modes in the incommensurate structure of the ladder-chain system Sr₁₄Cu₂₄O₄₁, ADRIAN GOZAR, CHRISTOPHER HOMES, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA, GIRSH BLUMBERG, Department of Physics and Astronomy, Rutgers, The State University of New Jersey, Piscataway, New Jersey 08854, USA, VERNER THORSMOLLE¹, HENRIK RONNOW, Laboratory for Quantum Magnetism, Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015, Switzerland — We report on low energy Raman and infra-red (IR) excitations in Sr₁₄Cu₂₄O₄₁. Two modes are observed starting from room temperature in the 1-2 meV range. One is a fully symmetric Raman mode and the other, observed in c-axis reflectance, is an excitation carrying a dipole moment along the chain/ladder direction. We associate these modes with the gapped c-axis sliding motions of the charged, incommensurate CuO₂ chains and Sr₂Cu₂O₃ ladder layers. This approach is able to quantitatively explain the range and relative energies of these excitations which are sensitive probes of the charge and spin density-wave ordering in the "14-24-41" systems.

10:48AM P37.00015 Dynamics of Sr₁₄Cu₂₄O₄₁ in a transient high intensity THz field, ELSA ABREU, Boston University, Department of Physics, 590 Commonwealth Avenue, Boston MA, USA, RAVI SINGH, University of Warwick, Department of Physics, Coventry CV4 7AL, UK, VERNER THORSMOLLE, Departement de Physique de la matiere condensee, Universite de Geneve, CH-1211 Geneve 4, Switzerland, GEETHA BALAKRISHNAN, University of Warwick, Department of Physics, Coventry CV4 7AL, UK, RICHARD AVERITT, Boston University, Department of Physics, 590 Commonwealth Avenue, Boston MA, USA — Over the past few years new techniques have become available to generate electromagnetic radiation with high electric field values in the THz range [1], allowing the dynamic study of materials whose excitations lie in the far infrared frequency range. This is the case of many charge density wave compounds, which exhibit a collective response due to pinning. Sr₁₄Cu₂₄O₄₁ is a charge density wave compound of particular interest, given its quasi one-dimensional structure consisting of alternating layers of Cu₂O₃ chains and CuO₂ ladders [2]. Understanding the dynamics of Sr₁₄Cu₂₄O₄₁ excitations in the far infrared has the potential not only to shed light onto the complex nature of charge ordering in this material, but also to help provide a better understanding of the nature of superconducting behavior in two-dimensional high temperature superconducting cuprates. In our work, THz pulses generated using a LiNbO₃ crystal interact with single crystal Sr₁₄Cu₂₄O₄₁ samples grown by the traveling solvent floating zone method. We will present preliminary results of a high field THz study of the dynamics of Sr₁₄Cu₂₄O₄₁. [1] Jepsen et al., Laser Phot Rev 5 124 (2011) [2] Gorshunov et al., Phys Rev B 66 060508 (2002)

Wednesday, February 29, 2012 8:00AM - 10:36AM — Session P40 DBIO: Protein Fluctuations and Conformation Changes 156A

8:00AM P40.00001 Atomistic simulations of the MS2 coat protein conformational transition, MATTHEW PERKETT, FRANCESCO PONTIGGIA, MICHAEL HAGAN, Brandeis University — During the replication of many viruses, hundreds to thousands of proteins self-assemble to form a protective protein coat, called a capsid, around the viral nucleic acid. Often these proteins have identical amino acid sequences with slightly different, or quasi-equivalent, conformations, which join in precise spatial arrangements. Although the structure of completed capsids is known to atomic resolution, little is known about the assembly intermediates and how protein conformations are selected during assembly. In this talk, we will use all-atom simulations to investigate how protein-RNA interactions guide conformational transitions of capsid proteins from the single-stranded RNA bacteriophage MS2. Since conformational changes occur on timescales which are not accessible to all-atom simulations, we use enhanced sampling methods to sample probable transition pathways and corresponding free energy profiles. Specifically, we will present free energy profiles associated with the MS2 capsid protein conformation in the presence and absence of RNA.

8:12AM P40.00002 Conformational changes of surface immobilized proteins studied by combined Atomic Force Microscopy and Fluorescence Spectroscopy, DANIEL RIZZO, CRISTIAN STAIL, Physics and Astronomy, Tufts University — Atomic Force Microscopy (AFM) and Fluorescence Spectroscopy techniques have provided unique methods for characterizing conformational changes in proteins. Here we are using a technique called nanografting to immobilize proteins at well defined locations on atomically flat surfaces. In nanografting the AFM tip is used to shave alkanethiol molecules from a prescribed patch on a surface coated with an alkanethiol monolayer. Thiol-linked proteins in the surrounding solution are then able to self assemble on the newly exposed surface patch in a highly ordered array of the order of 100nm. Stable and meta-stable conformations of fluorescently tagged proteins and other molecules assembled in this manner can then be characterized using a combination of AFM and Fluorescent Resonance Energy Transfer (FRET). Due to the high spatial, temporal and force resolution provided by both AFM and FRET, a free energy landscape of the protein may be determined using this technique.

8:24AM P40.00003 The Glassy State of Crambin and the THz Time Scale Fluctuations Related to Protein Function, KRISTINA WOODS, BEDIHA BESER, Carnegie Mellon University — THz experiments have been used to characterize the picosecond time scale fluctuations taking place in the model protein crambin. Using both hydration and temperature as an experimental parameter, we have successfully identified the collective fluctuations ($\leq 200 \text{ cm}^{-1}$) in the protein (Figure 1). Observation of the transition of the protein dynamics in the THz spectrum from both below and above the glass transition temperature (T_g) provides unique insight into microscopic interactions and modes that allow the solvent to couple with the protein dynamics (Figure 2). Our findings suggest that the solvent dynamics on the picosecond time scale not only contribute to the flexibility of the protein but also provides a dynamical parameter that allows the protein to modulate local regions of its structure that are distinct from the protein whole. These distinct dynamical regions of the protein may be important for energy transport and hence, linked with protein function.

8:36AM P40.00004 Stabilization of peptide helices by length and vibrational free energies: *Ab initio* case study of polyalanine, MARIANA ROSSI, VOLKER BLUM, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin — Helices are one of the most abundant secondary structure “building blocks” of polypeptides and proteins. Here, we explore helix stabilization as a function of peptide length and temperature [harmonic approximation to the vibrational free energy (FE)], for the alanine-based peptide, Ac-Ala_n-LysH⁺ $n=4-15$, in the gas phase. For $n=4-8$, we predict the lowest energy structures in density-functional theory, using the van der Waals (vdW) corrected[1] PBE exchange-correlation potential. α -helices become the lowest energy structures at $n \approx 7-8$ on the potential energy surface, but only barely and if including vdW interactions. At finite temperatures, the helices are further stabilized over compact conformers. While the vibrational entropy is the leading stabilizing term at 300 K, also the zero-point-energies favor the helical structures. For $n \geq 8$, the α -helix should be the only accessible conformer in the FE surface at 300 K, in agreement with experiment[2] and with our own comparison[3] of calculated *ab initio* anharmonic IR spectra to experimental IR multiple photon dissociation data for $n=5, 10$, and 15. [1] Tkatchenko and Scheffler, PRL 102, 073055 (2009); [2] Kohtani and Jarrold, JACS 108, 8454 (2004); [3] Rossi et al., JPCL 1, 3465 (2010).

8:48AM P40.00005 A Physics-based Approach of Coarse-graining the cytoplasm of *E. coli*¹, QIAN WANG, MARGARET CHEUNG, University of Houston — We have investigated protein stability in an environment of *E. coli* cytoplasm using coarse-grained computer simulations. To coarse-grain a small slide of *E. coli*'s cytoplasm consisting of over 16 million atoms, we developed a self-assembled clustering algorithm (CGCYTO). CGCYTO uses a tunable resolution parameter (λ , ranging from 0 to 1) to justify the resolution of a cytoplasm, depending on the size of a test protein for the computation of covolumes and the volume of a macromolecule in the cytoplasm. We compared the results from a polydisperse cytoplasm model (PD model) from CGCYTO with two other coarse-grained hard-sphere cytoplasm models: (1) F70 model, macromolecules in the cytoplasm were modeled by homogeneous hard spheres with a radius of 55Å and (2) HS model, each macromolecule in the cytoplasm is modeled by hard spheres of various sizes. It was found that the folding temperature T_f of a test protein (apoazurin) is ~ 5 degrees higher in a PD model than that in a F70 model. In addition, there is a deviation of 1.7 degrees on T_f when an apoazurin is randomly placed at different voids formed by particle fluctuations in a PD model, 0.7 degrees higher than that in a HS model.

9:00AM P40.00006 Investigation of flexibility in Myosin V using a new 3D mechanical model, MAHDI HAGHSHEENAS-JARYANI, Department of Mechanical Engineering, University of Texas at Arlington — This paper presents the development of a three dimensional rigid multibody model for the simulation and analysis of motor protein locomotion. The interesting aspect of this model is that it retains the mass properties, in contrast to the commonly used models which omit mass properties at the nano scale. The disproportionate size of the small mass of Myosin V relative to the large viscous friction forces requires a small integration step size that leads to a long simulation run time; however, the proposed model can be numerically integrated in a reasonable amount of time. This paper discusses modeling flexibility in the protein as an extension of the original rigid body model. Empirical studies have shown that Myosin V's neck domain can be considered as three pairs of tandem elements called IQ motifs which can bending at junctures between them. Therefore, each neck is modeled by three rigid bodies connected by ball-and-socket joints together, rather than single rigid body has been used in the previous works. Euler parameters are used to model the orientation of bodies in order to eliminate singularities in the description of orientation. In order to accomplish this, the equations of motion are reduced to minimal form using changing holonomic and non-holonomic constraints applied to the model which represent the normalization of the Euler parameters as well as contact and impact non-penetration conditions. The differences between the dynamic behavior of the new mechanical model, with flexible neck domains, and the original rigid body model are compared using simulation results.

9:12AM P40.00007 Barrel fluctuation and oxygen diffusion pathways in the monomeric fluorescent proteins, CHOLA REGMI, PREM CHAPAGAIN, YUBA BHANDARI, ILAN CHEMMAMA, BERNARD GERSTMAN, Florida International University — Fluorescent proteins are valuable tools as biochemical markers for studying cellular processes. Improving the photostability of the FPs is highly desirable in biochemical, biomedical and cell biology. Oxygen is necessary for the proper maturation of the chromophore in fluorescent proteins (FPs), but photobleaching of FPs is also oxygen sensitive. The photobleaching of the monomeric variant of RFPs has been attributed to the lack of proper shielding against oxygen or other small molecules, ions or halides. We use molecular dynamics simulation to investigate the protein barrel fluctuations in mCherry, one of the most useful monomeric mFruit variant of RFPs. We also employ oxygen diffusion simulations to search for possible pathways of oxygen to the chromophore. The ultimate goal is to use the results of these calculations to propose amino acid substitutions that will block the oxygen pathways and prevent photobleaching in the engineered proteins.

9:24AM P40.00008 Protein Dynamics Studied by Quasi-elastic Neutron Scattering¹, XIANG-QIANG (ROSIE) CHU, EUGENE MAMONTOV, Oak Ridge National Lab, MARCO LAGI, SOW-HSIN CHEN, MIT, MANAVALAN GAJAPATHY, JOSEPH NG, University of Alabama in Huntsville, KEVIN WEISS, LEIGHTON COATES, Oak Ridge National Lab, EMILIANO FRATINI, PIERO BAGLIONI, University of Florence — The biological function and activities of proteins are intimately related to their structures and dynamics. Nowadays, neutron scattering is one of the most powerful tools to study the protein dynamics. In this study, we use quasielastic neutron scattering (QENS) at the Spallation Neutron Source, ORNL, to study relaxational dynamics of two structurally different proteins — hen egg white lysozyme and an inorganic pyrophosphatase from a hyperthermophile, in the time range of 10ps to 1ns. We experimentally prove that the slow dynamics of globular proteins can be described by the mode-coupling theory (MCT) that was originally developed for glass-forming molecular liquids. The MCT predicts the appearance of a logarithmic decay for a glass-forming liquid. Such dynamic behavior is also observed by recent molecular dynamics (MD) simulations on protein molecules. In addition, we compare the temperature dependence of the dynamics of the two proteins with completely different activity profiles. Our results greatly help understanding the relation between protein dynamics and their biological functions.

¹This research is supported by the U.S. Department of Energy, managed by UT-Battelle, LLC, under contract no. DE-AC05-00OR22725.

9:36AM P40.00009 Intrinsic Mean Square Displacement in Proteins, DERYA VURAL, HENRY R. GLYDE, Department of Physics and Astronomy, University of Delaware — The dynamics of biological molecules is investigated in neutron scattering experiments, in molecular dynamics simulations, and using analytical theory. Specifically, the mean square displacement (MSD), $\langle r^2 \rangle_{exp}$, of hydrogen in proteins is determined from measurements of the incoherent elastic neutron scattering intensity (ENSI). The MSD, $\langle r^2 \rangle_{exp}$, is usually obtained from the dependence of the ENSI on the scattering wave vector Q . The MSD increases with increasing temperature reaching large values at room temperature. Large MSD is often associated with and used as an indicator of protein function. The observed MSD, however, depends on the energy resolution of the neutron spectrometer employed. We present a method, a first attempt, to extract the intrinsic MSD of hydrogen in protein from measurements, one that is independent of the instrument resolution. The method consists of a model of the ENSI that contains (1) the intrinsic MSD, (2) the instrument resolution width and (3) a parameter describing the motional processes that contribute to the MSD. Several examples of intrinsic MSDs $\langle r^2 \rangle$ in proteins obtained from fitting to data in the existing literature will be presented.

9:48AM P40.00010 Scaling Behavior in Twisted, Helical and Undulating Lysozyme Amyloid Fibrils, RAFFAELE MEZZENGA, CECILE LARA, JOZEF ADAMCIK, IVAN USOV, SOPHIA JORDENS, ETH Zurich — We combine atomic force microscopy single-molecule statistical analysis with polymer physics concepts to study the molecular conformations of lysozyme amyloid fibrils. We use different denaturation conditions to yield amyloid fibrils of different types. At 90 °C and pH2, highly laminated twisted and helical ribbons are found, in which as many as 17 protofilaments pack laterally for a total width approaching 180 nm. In the case of 60 °C and pH2, we find thin, wavy fibrils, in which the scaling behavior varies at multiple length scales. We use bond and pair correlation functions, end-to-end distribution and worm-like chain model to identify 3 characteristic length scales. At short length scales there is a first bending transition of the fibrils, corresponding to a bending length L_b . At slightly larger length scales ($>2L_b$), the fibrils become pseudoperiodic and start to undulate. Finally, at length scales larger than the persistence length L_p , the fibrils become flexible and are well described by a 2D self-avoiding random walk. We interpret these results in terms of the periodic fluctuations of the cross-section orientation of the fibrils (twisting) and the impact these have on the area moment of inertia and the corresponding propensity of the fibrils to bend.

10:00AM P40.00011 Probing Volume Changes and the Intracellular Water in Single Erythrocytes, SANGHOON PARK, SILKI ARORA, JENNIFER MAUSER, DEBOPAM CHAKRABARTI, ALFONS SCHULTE, University of Central Florida — In the living cell, water is one of the most abundant substances, and cells have developed very efficient machinery for transporting water in and out. Erythrocytes can undergo large, but reversible, volume changes under hydrostatic pressure and a possible mechanism may involve transport of water. We employ confocal micro-Raman spectroscopy over the frequency range from 150 to 4000 cm^{-1} to probe both the intracellular hemoglobin and water in individual red blood cells under physiological conditions. We investigate changes in the OH stretch bands near 3400 cm^{-1} due to the cellular water. Results of experiments that employ variations in external parameters such as pressure will be presented.

10:12AM P40.00012 Effects of pressure on the protein barrel and the chromophore interactions in mCherry, YUBA BHANDARI, PREM CHAPAGAIN, CHOLA REGMI, BERNARD GERSTMAN, Florida International University — Fluorescent proteins (FP) can be attached to proteins of interest, which makes it possible to study the movement, localization and many other physiological processes of the tagged proteins. A number of fluorescent proteins have been genetically engineered to enhance their intensity, photo-stability, pH-stability etc. The structural fluctuations of FPs determine the ease of access of small molecules like oxygen and may be an important consideration for their fluorescence spectrum and stability. A protein's response to pressure perturbations provides useful insights for understanding their folding and dynamics. Experiments have shown that application of pressure affects both the fluorescence peak as well as the quantum yield of the protein. We report on molecular dynamics computational investigations of the effect of pressure on the fluctuations of the beta barrel and the structure of the chromophore of a well characterized Red Fluorescent Protein, mCherry. We discuss our results on how pressure affects the ability of water and other ions to penetrate the barrel to reach the chromophore, as well as the effect on the time dependent hydrogen bonding network in the chromophore's cavity region.

10:24AM P40.00013 Thermal response of proteins (histone H2AX, H3.1) by a coarse-grained Monte Carlo simulation with a knowledge-based phenomenological potential¹, MIRIAM FRITSCHKE, DIETER HEERMANN, University of Heidelberg, Germany, RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Using a coarse-grained bond fluctuating model, we investigate structure and dynamics of two histones, H2AX (143 residues) and H3.1 (136 residues) as a function of temperature (T). A knowledge based contact matrix is used as an input for a phenomenological residue-residue interaction in a generalized Lennard-Jones potential. Metropolis algorithm is used to execute stochastic movement of each residue. A number of local and global physical quantities are analyzed. Despite unique energy and mobility profiles of its residues in a specific sequence, the histone H3.1 appears to undergo a structural transformation from a random coil to a globular conformation on reducing the temperature. The radius of gyration of the histone H2AX, in contrast, exhibits a non-monotonic dependence on temperature with a maximum at a characteristic temperature (T_c) where crossover occurs from a positive (stretching below T_c) to negative (contraction above T_c) thermal response on increasing T . Multi-scale structures of the proteins are examined by a detailed analysis of their structure functions.

¹This work is supported by the Air Force Research Laboratory.

Wednesday, February 29, 2012 8:00AM - 10:48AM —
Session P41 DFD: Drops, Bubbles and Interfacial Fluid Mechanics 156B

8:00AM P41.00001 The Life and Death of the Air Film Beneath an Impacting Drop , JOHN KOLINSKI, Harvard School of Engineering and Applied Sciences, Cambridge, MA, USA, SHMUEL RUBINSTEIN, Weizmann Institute of Science, Physics of Complex Systems, Rehovot, Israel, L. MAHADEVAN, Harvard School of Engineering and Applied Sciences, Cambridge, MA, USA — Droplet impact is ubiquitous in our everyday experience; yet many mysteries associated with the phenomenon remain, including the role played by air during the impact process. When a liquid meets a solid surface in an atmosphere, it must drain the air beneath it before initiating contact. In spite of the relatively low viscosity of the air, recent experiments and simulations suggest that this drainage dominates the dynamics of drop impact. Here I present recent experimental work, wherein Total Internal Reflection (TIR) microscopy is used to directly observe the thin air films that develop above the impact surface. We find that the formation of the thin air film is insensitive to liquid viscosity over a range of impact velocities, confirming prior theoretical predictions of thin air film formation. Going beyond this, the viscous response of the drop is also found to be important - high viscosity liquids maintain a steep front that progresses outward as the breadth of the air film increases, whereas lower viscosity liquids broaden without a steep front, suggesting a transition in the kinematics of the air liquid interface.

8:12AM P41.00002 Manipulating Leidenfrost temperature with surface modification , HYUK-MIN KWON, Massachusetts Institute of Technology, JACY BIRD, Boston University, KRIPA VARANASI, Massachusetts Institute of Technology — When a drop contacts a surface that is at a sufficiently high temperature, the drop can float on it's own vapor in a process known as the Leidenfrost effect. Although it is known that the critical temperature needed to achieve this effect depends on the properties of the drop and its vapor, often these parameters are fixed for a particular process. Here, we demonstrate a new way to control the critical temperature through the surface structure.

8:24AM P41.00003 Reducing contact time of drops on superhydrophobic surfaces , R. DHIMAN, J.C. BIRD, H. KWON, K.K. VARANASI, Massachusetts Institute of Technology — When water drops impact on to a superhydrophobic surface, the drops can recoil to such an extent that they completely bounce off the solid material. The time it takes for the drop to spread and recoil the contact time scales with the hydrodynamic inertial-capillary timescale. However, there is evidence that the coefficient of this scaling depends on surface-structure interactions, such as pinning. Here we investigate how surface interactions can influence droplet contact time, and we compare our results to existing models. We highlight an assumption in the current theory that imposes a lower-bound on the contact time. By designing around this constraint, we demonstrate novel superhydrophobic surfaces on which water droplets impact with shorter contact times than previously thought possible.

8:36AM P41.00004 Hydrodynamic self-rectification: A novel mechanism for generating uniform static droplet arrays , SIVA VANAPALLI, SWASTIKA BITHI, MENG SUN, Texas Tech University — Microfluidic static droplet arrays are a powerful means to simultaneously monitor many biochemical reactions in individual drops. We report a new mechanism for generating exceptionally monodisperse microfluidic droplet arrays. When a train of surfactant-free confined droplets are introduced into a fluidic network with hydrodynamic traps, the droplets are immobilized in the traps due to collective hydrodynamic resistive interactions. In the event, that an immobilized drop either under-fills or overfills the trap, we find that subsequent drops rectify its volume through coalescence, followed by break-up. This self-rectification mechanism thus yields highly monodisperse static droplet arrays. We map the phase space in terms of drop size, spacing and capillary number and find a broad window where this mechanism operates. Because this mechanism alleviates the need to control drop size and spacing in the train to create arrays, we demonstrate its capability to create static arrays with tuneable drop volumes and variable composition.

8:48AM P41.00005 In Situ Observation of Liquid Capillary Bridges on Superhydrophobic Surfaces , ADAM PAXSON, SUSHANT ANAND, KRIPA VARANASI, MIT — We describe a new technique for observing the dynamic behavior of the contact line of a liquid droplet on a superhydrophobic surface using environmental scanning electron microscopy. We find that on a surface patterned with an array of superhydrophobic micropillars, the receding contact line exhibits discrete hierarchical de-pinning events. As the macroscopic contact line recedes across the pillars, capillary bridges are formed along with microscale contact lines, thus perpetuating a self-similar wetting condition. We are able to measure the local receding angle and find that it follows the Gibbs criterion of depinning. By considering the line density of the microscale features and the pinning strength of each of those features, we relate the macroscopic adhesion force to that derived from a model based on pinning of the capillary bridges.

9:00AM P41.00006 Two particle microrheology of quasi-2D viscous systems in the limit of shallow bulk layer , THIBAUT DIVOUX, Ecole Normale Supérieure de Lyon, 46 allée d'Italie, 69007 Lyon, France, KENNETH DESMOND, JAMES SEBEL, ERIC WEEKS, Department of Physics, Emory University, Atlanta, Georgia 30322, USA — Human serum albumin (HSA) protein molecules at an air-water interface is a model system for which it is difficult to decouple the properties of the 2D interfacial film from those of the 3D fluid. Here we focus on the influence of the bulk confinement (i.e. the thickness of the layer of water) on the dynamics of HSA at an air-water interface. To do so, we have developed a setup which allows us to control the depth of the water layer over which HSA protein molecules are dispersed. In particular, we investigate the limit of shallow layers, for which we report measurements of the spatially correlated motion of colloidal particles embedded at the interface, for different surface viscosities. We describe the influence of the bulk finite size on the behaviour of the spatial correlation functions of the particle motion, and extend the description of the correlation functions in terms of a master curve first obtained for large bulk volumes, to the limit of shallow layers.

9:12AM P41.00007 Measuring interfacial viscosity using macro- and micro-rheology , JAMES SEBEL, KENNETH DESMOND, ERIC R. WEEKS, THIBAUT DIVOUX, Emory University — We measure the viscous moduli of thin films using two different methods. First, we use a magnetic needle viscometer. Our apparatus employs Helmholtz coils to control the position and orientation of the needle in the film. By driving the needle we can produce a response in the film which allows us to probe the bulk viscous properties of the film. Second, we use single particle microrheology to probe the local properties of the film. Tracking the mean-squared displacement of particles as they undergo Brownian motion probes the local viscous properties of any heterogeneous domains. Coupling this technique with the magnetic needle viscometer provides information on the effect local viscous properties have on the bulk properties.

9:24AM P41.00008 Molecular Modeling of Three Phase Contact for Static and Dynamic Contact Angle Phenomena , ATEEQUE MALANI, Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA, MIGUEL AMAT, Department of Chemical and Biological Engineering, Princeton University, Princeton, NJ, ANILKUMAR RAGHAVANPILLAI, E.I. du Pont de Nemours, Wilmington, DE, ERNEST WYSONG, Experimental Section, E.I. du Pont de Nemours, Wilmington, DE, GREGORY RUTLEDGE, Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA — Interfacial phenomena arise in a number of industrially important situations, such as repellency of liquids on surfaces, condensation, etc. In designing materials for such applications, the key component is their wetting behavior, which is characterized by three-phase static and dynamic contact angle phenomena. Molecular modeling has the potential to provide basic insight into the detailed picture of the three-phase contact line resolved on the sub-nanometer scale which is essential for the success of these materials. We have proposed a computational strategy to study three-phase contact phenomena, where buoyancy of a solid rod or particle is studied in a planar liquid film. The contact angle is readily evaluated by measuring the position of solid and liquid interfaces. As proof of concept, the methodology has been validated extensively using a simple Lennard-Jones (LJ) fluid in contact with an LJ surface. In the dynamic contact angle analysis, the evolution of contact angle as a function of force applied to the rod or particle is characterized by the pinning and slipping of the three phase contact line. Ultimately, complete wetting or de-wetting is observed, allowing molecular level characterization of the contact angle hysteresis.

9:36AM P41.00009 Nonlinear electrohydrodynamics of a viscous droplet, PAUL SALIPANTE, PETIA VLAHOVSKA, Brown University — A classic result due to G.I.Taylor is that a drop placed in a uniform electric field adopts a prolate or oblate spheroidal shape, the flow and shape being axisymmetrically aligned with the applied field. We report an instability and transition to a nonaxisymmetric rotational flow in strong fields, similar to the rotation of solid dielectric spheres observed by Quincke in the 19th century. Our experiments reveal novel droplet behaviors such as tumbling, oscillations and chaotic dynamics even under creeping flow conditions. A phase diagram demonstrates the dependence of these behaviors on drop size, viscosity ratio and electric field strength. The theoretical model, which includes anisotropy in the polarization relaxation, elucidates the interplay of interface deformation and charging as the source of the rich nonlinear dynamics.

9:48AM P41.00010 Breakup of Bubbles or Drops by Capillary Waves Induced by Coalescence or Other Excitations, FENG HUA ZHANG, Singapore-MIT Alliance, National University of Singapore, Singapore, PETER TABOREK, Department of Physics and Astronomy, University of California, Irvine, USA, JUSTIN BURTON, James Franck Institute, University of Chicago, Chicago, USA, BOO CHEONG KHOO, Singapore-MIT Alliance, National University of Singapore, Singapore, SIGGI THORODDSEN, King Abdullah University of Science and Technology, Saudi Arabia — Capillary breakup of a bubble or drop by various excitations is ubiquitous in both nature and technology. Examples include coalescence with another bubble or drop, wetting on a solid surface, impact on a solid surface, detachment from a nozzle, or vibrations driven by acoustic, electrical, or magnetic fields. When the excitation ceases, capillary forces on the surface naturally drive the deformed bubble or drop to recover its spherical shape. However, when the viscosity is small, this recovery can lead to nonlinear oscillations of the interface and a singularity in the flow. Here we use high-speed imaging to investigate the coalescence of bubbles and drops of various sizes. In many cases, coalescence leads to pinch-off events and the formation of the satellite and sub-satellite. Our experiments use pressured xenon gas in glycerol/water mixtures so that the density ratio and viscosity ratio can be varied over many orders of magnitude. We characterize the generation, propagation, and convergence of capillary waves, the formation time and sizes of satellites, and the dynamics of two-fluid pinch-off as a function of the density ratio and viscosity ratio. The work shall benefit the wide-spread applications and fulfill the scientific and public curiosities.

10:00AM P41.00011 Thermo-actuated migration in a micro-system, MARIE-CAROLINE JULLIEN, UMR 7083 CNRS ESPCI, BERTRAND SELVA, Unité Mixte Rhodia CNRS 5258, ISABELLE CANTAT, Université de Rennes 1, MMN, LABORATOIRE GULLIVER TEAM, LOF TEAM, INSTITUT DE PHYSIQUE DE RENNES TEAM — Digital microfluidics require element displacement by simple means featuring high integration rates. Within this context, the transport and handling of elements constitutes a problem [Squires and Quake, 2005]. This context has rekindled interest in the Marangoni surface effect, which refers to tangential stresses along an interface. Producing a surface tension gradient by imposing a temperature gradient is especially efficient and easy to control. In a recent paper, we have shown [Selva et al., Phys. Fluids (2011)] that a bubble undergoing a constant temperature gradient is indeed set into motion. However, the direction of motion (toward the cooler side) is in contradiction with experiments performed at the millimetre scale in which bubble migration is driven towards hotter regions. We believe this observation is due to the PDMS deformability. Indeed, PDMS expands when the temperature increases. A temperature gradient inside a microsystem results in a cavity thickness gradient, and thus leads to the bubble travelling towards the thicker part of the cavity. The physical phenomena involved in such a system are multifaceted (PDMS dilation, thermocapillarity, solutocapillarity) and may have either complementary or opposite effects depending on the experimental conditions.

10:12AM P41.00012 Towards an effective surface tension at a foam/water interface¹, HERVE CAPS, ARIANE BRONFORT, CHARLES DUBOIS, GILES DELON, GRASP - University of Liege — Foams are defined as assemblies of gas bubbles immersed into a continuous liquid phase. Depending on the ration between the total volume occupied by the foam and the amount of liquid inside the foam, different rheological behaviors are observed. Beside the numerous studies on the foam's bulk behavior, poor is known concerning the interface between a foam and the liquid bath it has been generated from. This interface is however separating two identical liquids where, one of these, also contained a dispersed phase. Our studies aim in describing this interface in terms of an effective surface tension, while considering the foam as a continuous medium. Monodisperse foams are produced in Hele-Shaw cells and the features of the boundary between the foam and the baliquid pool is studied by means of hydrodynamical instabilities. Namely, Faraday waves, Rayleigh-Taylor instability and Saffmann-Taylor fingering are considered. Among these instabilities, the shearing of the interface is studied within a rotating drum experiment, similarly to the granular case.

¹ESA MAP - FNRS-FRS - Belspo Prodex

10:24AM P41.00013 Continuous dielectrophoretic centering of compound droplets, GREG RANDALL, BRENT BLUE, General Atomics — Compound droplets, or droplets-within-droplets, are traditionally key components in applications ranging from drug delivery to the food industry. Presently, millimeter-sized compound droplets are precursors for foam shell targets in inertial fusion energy work. A key constraint is a uniform foam shell thickness, which in turn requires a centered core in the compound droplet precursor. Previously, Bei et al. (2009, 2010) have shown that compound droplets could be centered in a static fluid using an electric field of 0.7 kV/cm at 20 MHz. To apply centering to existing or future applications, it is imperative to develop a continuous droplet centering process by overcoming the additional complications from motion. Here, we present analysis and experimental data of a continuous droplet centering device that uses an electric field to force a core droplet to the center of a moving compound drop. Our analysis focuses on how interfacial rheology and electrohydrodynamic flows affect the centering dynamics and droplet deformation. Proof-of-principle experiments are performed in a vertical channel using buoyancy to drive a solution of compound droplets stabilized with phospholipid and protein emulsifiers through a kV/cm electric field.

10:36AM P41.00014 The Dynamics of Coupled Droplets Under Gravity Condition, HAIDER HEKIRI, TAKUMI HAWA, School of Aerospace and Mechanical Engineering, The University of Oklahoma — The dynamics of a two-dimensional, incompressible, and two coupled spherical-cap water droplets pinned in a straight channel is investigated under gravity condition through the use of CFD. Since the capillary length is three times as large as the channel width, the effect of gravity is small but not negligible. In this simulations FLUENT with a 2-D pressure based solver is utilized. The suspended droplet states are measured by the location of the center of mass of the droplet. Under no gravity condition we find that there is a critical volume, V_c , where a bifurcation of asymmetric states occurs. However, gravity changes the pitchfork bifurcation diagram of coupled droplets systems into two separate branches of equilibrium states. The primary branch describes a gradual and stable change of the droplet states from symmetric to non-symmetric as V is increased across V_c . The secondary branch appears at a certain modified critical volume, V_{mc} , and describes two additional non-symmetric states for $V > V_{mc}$. CFD demonstrated that the large-amplitude state along the secondary branch is stable whereas the small-amplitude states are unstable.

Session P42 DBIO GSNP: Focus Session: Evolutionary Systems Biology II - From molecules to cells 156C

8:00AM P42.00001 Statistical Physics Approaches to RNA Editing¹ , RALF BUNDSCHUH, Ohio State University — The central dogma of molecular Biology states that DNA is transcribed base by base into RNA which is in turn translated into proteins. However, some organisms edit their RNA before translation by inserting, deleting, or substituting individual or short stretches of bases. In many instances the mechanisms by which an organism recognizes the positions at which to edit or by which it performs the actual editing are unknown. One model system that stands out by its very high rate of on average one out of 25 bases being edited are the *Myxomycetes*, a class of slime molds. In this talk we will show how the computational methods and concepts from statistical Physics can be used to analyze DNA and protein sequence data to predict editing sites in these slime molds and to guide experiments that identified previously unknown types of editing as well as the complete set of editing events in the slime mold *Physarum polycephalum*.

¹This presentation is based on work supported by the National Science Foundation under grant number DMR-0706002.

8:36AM P42.00002 Biophysical Models of Evolution: Application to Transcription Factor Binding Sites in Yeast , MICHAEL MANHART, ALLAN HALDANE, ALEXANDRE MOROZOV, Rutgers University — There has been growing interest in understanding the physical driving forces of evolution at the molecular scale, in particular how biophysics determines the fitness landscapes that shape the evolution of DNA and proteins. To that end we study a model of molecular evolution that explicitly incorporates the underlying biophysics. Using population genetics, we derive a steady-state distribution of monomorphic populations evolving on an arbitrary fitness landscape. Compared to previous studies, we find this result is universal for a large class of population models and fully incorporates both stochastic effects and strong natural selection. This distribution can then be used to infer the underlying fitness landscape from genomic data. This model can be applied to a variety of systems, but we focus on transcription factor binding sites, which play a crucial role in gene regulatory networks. Since these sites must be bound for successful gene regulation, we consider a simple thermodynamic model of fitness as a function of the free energy for binding a transcription factor at the site. Using empirical energy matrices and genome-wide sets of binding sites from the yeast *Saccharomyces cerevisiae*, we use this model to infer the role of DNA-protein interaction physics in evolution.

8:48AM P42.00003 The Fitness of Genomic Order¹ , QIUCEN ZHANG, SAURABH VYAWAHARE, ROBERT AUSTIN, Department of Physics, Princeton University — Most bacteria have a single circular chromosome that can range in size from 160,000 to 12,200,000 base pairs. Considering the typical gene density, i.e. 1 gene per 1,000 base pairs, both the number of genes and the ways to arrange are huge. Intuitively, the arrangement of genes on the circle is not important if all of them can be replicated. However, there is typically one origin of replication, and when bacteria is attacked by genotoxic stress during replication, the whole replication process can not be finished. As a result, which gene is replicated first, which is second, ..., becomes very important. Experimentally, we found a broad increase of DNA copy number near the origin of replication (OriC) of bacteria *E.coli* (~3200 genes) under genotoxic stress. Since the genes near OriC are mostly efflux pump genes, we propose that there is fitness advantage for those rapid stress response genes got replicated first, because they can facilitate the replication of the rest of genome. Similar to bacterial evolution to present genomic order, in the somatic evolution of cancer, genomic shuffling was also frequently observed, especially under genotoxic chemotherapy. Such re-arrangement of genome can be viewed as a journey to optimal point in the rugged fitness landscape of genomic order.

9:00AM P42.00004 Plasticity of metabolic networks and the evolution of C4 photosynthesis , ELI BOGART, CHRIS MYERS, Cornell University — Over 50 groups of plants have independently developed a common mechanism (C4 photosynthesis) for increasing the efficiency of photosynthetic carbon dioxide assimilation. Understanding the high degree of evolvability of the C4 system could offer useful guidance for attempts to introduce it artificially to other plants. Previously, the nonlinear relationship between carbon dioxide levels and rates of carbon assimilation and photorespiration has prevented the application of genome-scale metabolic models to the problem of the evolution of the pathway. We apply a nonlinear optimization method to find feasible flux distributions in a plant metabolic model, allowing us to explore the plasticity of the metabolic network and characterize the fitness landscape of the transition from C3 to C4 photosynthesis.

9:12AM P42.00005 Uncovering principles of cellular decision-making , GUROL SUEL, UT Southwestern — Cells can cope with unpredictable environmental conditions by differentiating into appropriate states. In this talk, I will present our recent attempts to understand the role of genetic circuits in regulating the underlying process of cellular decision-making. Specifically, we are interested in how interactions within and across genetic circuits enable cells to choose among alternative fates. To address this question my laboratory is employing systems and synthetic biology approaches. Our ultimate goal is to uncover possible evolutionary pressures that may have selected for specific gene circuit architectures, dynamics and noise properties.

9:48AM P42.00006 Role of Multisite Phosphorylation in Timing of a Yeast Cell Cycle Event¹ , VOLKAN SEVIM, University of California, San Francisco, XIAOJING YANG, University of California, San Francisco; Peking University, KAI-YEUNG LAU, University of California, San Francisco, CHAO TANG, University of California, San Francisco; Peking University — We study the biochemical network that triggers the S phase in yeast cell cycle. Key components of this network are three proteins: two kinases and an inhibitor. First kinase, Cln1/2-Cdk, acts as an input signal, phosphorylating the inhibitor, Sic1. The second kinase, Clb5/6-Cdk, is sequestered into an inactive complex by Sic1. Clb5/6-Cdk is the output signal of the circuit. Sic1 has nine phosphorylation sites, and phosphorylation of six or more of them causes it to degrade rapidly, leading to a sharp rise of free Clb5/6-Cdk. Our experiments indicate that multisite phosphorylation (MSP) is responsible for the timing robustness of this sharp transition. We study the role of MSP in timing using computer simulations. Preliminary results indicate that, MSP does not bring timing robustness when each kinase can phosphorylate each site with identical specificity. We employ in silico evolution to find the specificity configuration for the phosphorylation sites that leads to most robust timing under extrinsic noise.

10:00AM P42.00007 Precision of sensing, memory and fluctuating environments , GERARDO AQUINO, ROBERT ENDRES, Division of Molecular Biosciences & Centre for Integrated Systems Biology at Imperial College, Imperial College London — Multiple cell types were recently shown to sense their chemical environment with astonishing accuracy, crucial for nutrient scavenging, mating, immune response, and development. It is currently unknown if this sensing near the single-molecule detection limit is due to highly precise single measurements, or due to learning over time. In this work, we analyze if cell memory can allow cells to sense beyond the current estimates of the fundamental physical limit. By merging Bayesian inference with information theoretic concepts, we derive analytical formulas which show that memory improves sensing in correlated fluctuating environments, but not in strongly uncorrelated environments. Despite many analogies with problem solving strategies in engineering, our theory shows fundamental differences in interpreting noisy stimuli in the microscopic and macroscopic world.

10:12AM P42.00008 Rapidly evolving microorganisms with high biofuel tolerance¹, SAURABH VYAWAHARE, QIUCEN ZHANG, WENDY LANG, ROBERT AUSTIN, Department of Physics, Princeton University, Princeton NJ 08544 — Replacing non-renewable energy sources is one of the biggest and most exciting challenges of our generation. Algae and bacteria are poised to become major renewable biofuels if strains can be developed that provide a high, consistent and robust yield of oil. One major stumbling block towards this goal is the lack of tolerance to high concentrations of biofuels like isobutanol. Using traditional bioengineering techniques to remedy this face the hurdle of identifying the correct pathway or gene to modify. But the multiplicity of interactions inside a cell makes it very hard to determine what to modify a priori. Instead, we propose a technology that does not require prior knowledge of the genes or pathways to modify. In our approach that marries microfabrication and ecology, spatial heterogeneity is used as a knob to speed up evolution in the desired direction. Recently, we have successfully used this approach to demonstrate the rapid emergence of bacterial antibiotic resistance in as little as ten hours. Here, we describe our experimental results in developing new strains of micro-organisms with high oil tolerance. Besides biofuel production, our work is also relevant to oil spill clean-ups.

10:24AM P42.00009 A Cahn-Hilliard model of vascularized tumor growth in a complex evolving confinement using a diffuse domain approach¹, YAO-LI CHUANG, University of New Mexico, Dept. Pathology, VITTORIO CRISTINI, University of New Mexico, Dept. Pathology and Dept. Chemical Engineering, YING CHEN, XIANGRONG LI, University of California, Irvine, Dept. Math, HERMANN FRIEBOES, University of Louisville, Dept. Bioengineering, JOHN LOWENGRUB, University of California, Irvine, Dept. Math — Understanding the spatiotemporal evolution of tumor growth is essential for developing effective strategies to treat cancers. Various studies have suggested that spatial heterogeneity during tumors growth is a key factor associated with subsequent tumor invasion and the effectiveness of chemotherapy. Spatial heterogeneity may arise due to morphological instability of the tumors and the complex tissue structure surrounding the tumors. In previous works, we have used a Cahn-Hilliard tumor growth model to study the morphological instability for tumors in non-resisting tissues. However, most tumors are surrounded by complex tissue structures and confined in the capsules of some organs or between certain basement membranes. The capsules and basement membranes may be distorted by interacting with the evolving tumors, affecting the morphological instability. Here we adopt a novel diffuse domain approach to adapt our previous Cahn-Hilliard model for tumor growth in such complex evolving environments. As an example, we apply the model to simulate the evolution of lymphoma in a lymph node, incorporating also the tumor-induced angiogenesis.

10:36AM P42.00010 Emergence of Information Transmission in a prebiotic RNA Reactor, BENEDIKT OBERMAYER, Harvard University, HUBERT KRAMMER, DIETER BRAUN, ULRICH GERLAND, LMU Muenchen — A poorly understood step in the transition from a chemical to a biological world is the emergence of self-replicating molecular systems. We study how a precursor for such a replicator might arise in a hydrothermal RNA reactor, which accumulates longer sequences from unbiased monomer influx and random ligation. In the reactor, intra- and intermolecular base pairing locally protects from random cleavage. Analyzing stochastic simulations, we observe a strong bias towards long sequences with complex secondary structures, which would facilitate the emergence of ribozymes. Further, we find temporal sequence correlations that constitute a signature of information transmission, weaker but of the same form as in a true replicator.

10:48AM P42.00011 Towards molecular evolution with thermal traps, CHRISTOF MAST, Systems Biophysics, SEVERIN SCHINK, Arnold-Sommerfeld-Center, HUBERT KRAMMER, Systems Biophysics, BENEDIKT OBERMAYER, Arnold-Sommerfeld-Center, ULRICH GERLAND, Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoScience, LMU Munich, DIETER BRAUN, Systems Biophysics and Center for Nanoscience, LMU Munich — Live evolves by replication and selection of nucleotide polymers. Our experiments aim to drive molecular replication and selection with physical nonequilibrium boundary conditions. We discuss three approaches. Replication Trap. Molecules are exponentially accumulated by a combination of thermophoresis and convection, driven both by the same thermal gradient [1]. We have shown last year that with the help of a polymerase protein, concurrent replication and accumulation is possible [2]. Convection is melting and annealing the DNA in an oscillatory pattern, doubling the DNA in each cycle. Trapped polymerization. The chemical equilibrium of polymerization is expected to shift in the thermal trap. As the trap accumulates the monomers, polymerization yields longer polymers. However, since the trap is exponentially length selective, distributions beyond exponential tails are predicted. Replication by selective degradation. Replication typically is discussed as template directed polymerization. We showed that selective degradation and a thermal trap leads to replication-like behavior using only non templated polymerization [3]. The progression of information is given by the faster degradation of single stranded over double stranded RNA. [1] PNAS 104, 9346 (2007) [2] PRL 104, 188102 (2010) [3] PRL 107, 018101 (2011)

8:00AM P43.00001 Tissue Refractive Index Fluctuations Report on Cancer Development, GABRIEL POPESCU, University of Illinois at Urbana-Champaign — The gold standard in histopathology relies on manual investigation of stained tissue biopsies. A sensitive and quantitative method for *in situ* tissue specimen inspection is highly desirable, as it will allow early disease diagnosis and automatic screening. Here we demonstrate that *quantitative phase imaging* of entire unstained biopsies has the potential to fulfill this requirement. Our data indicates that the refractive index distribution of histopathology slides, which contains information about the molecular scale organization of tissue, reveals prostate tumors. These optical maps report on subtle, *nanoscale morphological properties* of tissues and cells that cannot be recovered by common stains, including hematoxylin and eosin (H&E). We found that cancer progression significantly alters the tissue organization, as exhibited in our refractive index maps. Furthermore, using the quantitative phase information, we obtained the spatially resolved scattering mean free path and anisotropy factor *g* for entire biopsies and demonstrated their direct correlation with tumor presence. We found that these scattering parameters are able to distinguish between two adjacent grades, which is a difficult task and relevant for determining patient treatment. In essence, our results show that the tissue refractive index reports on the nanoscale tissue architecture and, in principle, can be used as an intrinsic marker for cancer diagnosis.

Session P44 DPOLY: Focus Session: Block Copolymer Micelles and Polymersomes 157C

8:00AM P44.00001 Modeling of Interactions Between Spherical Micelles for Diblock Copolymers in Selective Solvents, RAGHURAM THIAGARAJAN, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota — The self-assembly of spherical micelles formed in systems with a diblock copolymer AB, consisting of a solvent-philic block (B) and a solvent-phobic block (A), in selective solvents (S) is studied here. Effective interactions between spherical micelles for a model system are quantified using self-consistent field modeling in real space, for the dilute regime $\phi_{AB} < 0.2$, as well as using a pseudo-spectral implementation of SCFT, for the concentrated regime $\phi_{AB} > 0.2$. We show that the free energy of BCC, and FCC phases can be described in terms of a single effective pair potential that depends on micelle aggregation number, but the aggregation number changes significantly with concentration as well as temperature.

8:12AM P44.00002 Dissipative particle dynamics study of relationship between wall thickness and size in polymer vesicles¹, MENGYING XIAO, Nanjing University, Institute of Theoretical and Computational Chemistry, Key Laboratory of Mesoscopic Chemistry, RONG WANG, Nanjing University, Department of Polymer Science and Engineering, State Key Laboratory of Coordination Chemistry, DAIQIAN XIE, Nanjing University, Institute of Theoretical and Computational Chemistry, Key Laboratory of Mesoscopic Chemistry — Vesicles and membrane properties have long been thought to be essential for reproducing the natural environment of living cells. By using dissipative particle dynamics method, we have studied the relationship between wall thickness and size of vesicles obtained from A1BnA1 block copolymers, where block A is hydrophilic and block B is hydrophobic. Our findings suggest that, the wall thickness is sensitive to the size of vesicles at a low block length ratio of B/A, but insensitive to the size at a large ratio. It shows both weak and strong effects with a crossover point in between. These behaviors are consistent with the experimental results of Eisenberg and co-workers. Besides, an additional crossover point also has been observed. With the B/A ratio increases, the relationship goes from strong to weak behavior, and this transformation first appears to affect the outer area for large sized vesicles, and then to the inner area for small sized vesicles. These results may also be useful in delivery applications through controlling the hydrophobic membrane and the hydrophilic coronas.

¹This work has been supported by NNSFC (Nos. 20874046, 21074053 and 21133006) and NBRPC (No. 2010CB923303).

8:24AM P44.00003 Effect of Hydrophobic Block Length on Vesicle Formation of Block Copolymers¹, RONG WANG, Nanjing University, Department of Polymer Science and Engineering, State Key Laboratory of Coordination Chemistry, MENGYING XIAO, DAIQIAN XIE, Nanjing University, Institute of Theoretical and Computational Chemistry, Key Laboratory of Mesoscopic Chemistry — Self-assembly of amphiphilic block copolymers result in a wide range of aggregates in aqueous solution, including spheres, rods, lamellae, vesicles, and large compound vesicles with an inverted core-shell structure surrounded by hydrophilic surface. In the work, we carried out a systematic investigation of A1BnA1 triblock copolymers with different hydrophobic block length by using the dissipative particle dynamics (DPD). As the B/A ratio increase further, no well-defined disk-like micelles (bilayer structures) are seen. Spherical micelles rearrange internally and swell the hydrophilic group in the center until vesicles are formed. Because the longer chains appear to drift slowly, it is clear that the rearrangement process becomes slower in the system with longer hydrophobic block, which needs more time to form vesicles. The segregation of A segments (hydrophilic group) leaves in the internal layer when the two small spherical micelles merge into a larger one. We observe that the existence of the two pathways of vesicles formation based on the hydrophobic block length using DPD particle models.

¹This work has been supported by NNSFC (Nos. 20874046, 21074053 and 21133006) and NBRPC (No. 2010CB923303).

8:36AM P44.00004 Nanostructured assemblies from amphiphilic ABC multiblock polymers¹, MARC A. HILLMYER, University of Minnesota — Amphiphilic AB diblock copolymers containing a water compatible segment can self-assemble in aqueous media to give supramolecular structures that include simple spherical micelles and macromolecular vesicles termed polymersomes. Amphiphilic ABA triblocks with hydrophobic end blocks can adopt analogous structures but can also form gels at high polymer concentrations. The structural and chemical diversity demonstrated in block copolymer micelles and gels makes them attractive for applications ranging from drug delivery to personal care products to nanoreactors. The inclusion of a third block in amphiphilic ABC triblock systems can lead to a much wider array of self-assembled structures that depend not only on composition but also on block sequence, architecture and incompatibility considerations. I will present our recent efforts on tuning micelle and gel structure and behavior using controlled architecture ABC triblocks. The combination of diverse polymer segments into a single macromolecule is a powerful method for development of self-assembled structures with both new form and new function.

¹This work was supported primarily by the MRSEC Program of the National Science Foundation under Award Number DMR-0819885.

9:12AM P44.00005 The Morphology of Lipid Aggregates based on the Interplay among Molecular Architectures, Hydrophobic-Hydrophilic and Coulombic Interactions and their Kinetics, MU-PING NIEH, Institute of Materials Science, Department of Chemical, Materials and Biomolecular Engineering, University of Connecticut, Storrs, CT 06269 — Lipids resemble amphiphilic diblock copolymers in the many ways in terms of rich resultant structures, which are controlled by spontaneous curvature and molecular interaction, except that the molecular length scale of interest is smaller. One of the most commonly studied systems is so-called "bicelle" ("bilayered micelle"), which is composed of a long- and a short- chain lipid, spontaneously forming discoidal micelles in aqueous solutions under certain conditions. The lamellae of "bicellar mixtures" have been used as magnetically alignable templates for structural study of membrane-associated proteins since they provide a native bilayered environment for the proteins in study. In this talk, I will summarize how and why a variety of morphology can be obtained from the "bicellar" system based on the molecular architectures (spontaneous curvatures) of the lipids, inter-particle Coulombic interaction and hydrophobic-hydrophilic interaction. Most interestingly, many of these structures are kinetically controlled but have robust formation mechanisms and high stability. Currently, we are particularly interested in how the exchange rate of the lipid molecules affects the kinetics.

9:48AM P44.00006 Phase Behavior and Kinetics of Diblock Copolymer in Selective Solvent¹, JULIAN SPRING, RAMA BANSIL, Boston University — Synchrotron based time-resolved small angle x-ray scattering (SAXS) was used to study the kinetics of the formation of a gyroid phase in solutions of a poly (styrene -isoprene) (SI) diblock copolymer in dimethyl phthalate, a selective solvent for the polystyrene block. Temperature ramp measurements over the range of 70-130C show the transition from hexagonally-packed cylinders (HEX) to Gyroid phase for 75% and 80% (w/v) samples to be 117C and 96C, respectively. Results of temperature jump experiments to different jump depths to examine the kinetics of this transition will be presented. In addition to the Bragg scattering from the ordered phases, we were able to observe the temperature dependence of the diffuse scattering near $q=0$. The temperature dependence of the correlation length shows a crossover from $\sqrt{T}$ near the glass transition for polystyrene to linear in T near the HEX to Gyroid transition. The effect of adding low molecular weight linear homopolymer PS to the samples on the phase behavior will be discussed.

¹This research was supported by NSF-DMR grant no. 0804784.

10:00AM P44.00007 Phase Behavior of Gradient Copolymer Solution, GUNJA PANDAV, University of Texas at Austin, KEITH GALLOW, YUEH-LIN LOO, Princeton University, VENKAT GANESAN, University of Texas at Austin — We study the behavior of amphiphilic linear gradient copolymer chains under poor solvent conditions. Using Bond Fluctuation model and parallel tempering algorithm, we explore qualitative behavior of this class of polymers with varying gradient strength; which is the largest difference in the instantaneous composition along the polymer chain. Under poor solvent conditions, the chains collapse to form micelles. We find a linear dependence of hydrophilic to hydrophobic transition temperature on gradient strength. Systematic analysis of these clusters reveals a strong dependence of micelle properties on gradient strength. Also, we discuss our results with reference to recent experiments on synthesis and cloud point depression in gradient copolymers confirming gradient strength as key parameter in tuning micelle properties.

10:12AM P44.00008 Self-Assembly of Novel Amphiphilic 21-Arm, Star-Like Coil-Rod Diblock Copolymers at Interfaces, ZHIQUN LIN, LEI ZHAO, XINCHANG PANG, CHAOWEI FENG, Georgia Institute of Technology — A series of novel amphiphilic 21-arm, star-like diblock copolymers, poly(acrylic acid)-*b*-poly(3-hexylthiophene) (PAA-*b*-P3HT) based on β -cyclodextrin (β -CD) with well defined molecular architectures and ratio of two chemically distinct blocks were prepared, for the first time, via a combination of quasi-living Grignard metathesis method (GRIM), click reaction, and atom transfer radical polymerization (ATRP). The star-like PAA-*b*-P3HT diblock copolymers consist of hydrophilic coil-like PAA cores and hydrophobic rod-like P3HT shells with narrow molecular weight distribution and controllable molecular weight of each block. Owing to the compact structure, the amphiphilic star-like PAA-*b*-P3HT formed a unimolecular micelle. Vesicles based on these novel amphiphilic star-like, coil-rod diblock copolymers were readily produced at the oil/water interface by crosslinking hydrophilic coil-like PAA cores with a bifunctional crosslinker, ethylenediamine. They also self-assembled into a nanotubular structure at the air/water interface.

10:24AM P44.00009 Formation and Characterization of Anisotropic Block Copolymer Gels, CHYA YAN LIAW, DERK JOESTER, WESLEY BURGHARDT, KENNETH SHULL, Northwestern University — Cylindrical micelles formed from block copolymer solutions closely mimic biological fibers that are presumed to guide mineral formation during biosynthesis of hard tissues like bone. The goal of our work is to use acrylic block copolymers as oriented templates for studying mineral formation reactions in model systems where the structure of the underlying template is well characterized and reproducible. Self-consistent mean field theory is first applied to investigate the thermodynamically stable micellar morphologies as a function of temperature and block copolymer composition. Small-angle x-ray scattering, optical birefringence and shear rheometry are used to study the morphology development during thermal processing. Initial experiments are based on a thermally-reversible alcohol-soluble system that can be converted to an aqueous gel by hydrolysis of a poly(*t*-butyl methacrylate) block to a poly(methacrylic acid) block. Aligned cylindrical domains are formed in the alcohol-based system when shear is applied in an appropriate temperature regime, which is below the critical micelle temperature but above the temperature at which the relaxation time of the gels becomes too large. Processing strategies for producing the desired cylindrical morphologies are being developed that account for both thermodynamic and kinetic effects.

10:36AM P44.00010 Stimuli-responsive block copolypeptides, VENKATA KRISHNA KOTHARANGANNAGARI, University of Fribourg, ANTONI SANCHEZ-FERRER, ETH Zurich, JANNE RUOKOLAINEN, Aalto University, RAFFAELE MEZZENGA, ETH Zurich — Stimuli-responsive polypeptide block copolymers are appealing systems due to the morphological polymorphic states they can exhibit in selective solvents, including micelles, vesicles, fibrils, and more complex supramolecular aggregates. Their morphologies can be engineered a-priori by the relative block lengths, the solvent composition, and their concentration. However controlling the morphology upon external stimuli offers clear benefits, since changes in structure and morphology can be induced on demand. In this talk, we present two examples of stimuli-responsive block copolypeptides: in a first case, a photoresponsive PLGA-PEO diblock is discussed capable to reversibly undergo micellization-dissolution-micellization upon visible or UV light exposure, due to spiropyran units decorating the PLGA block; in the second case a PBLG-PDMS-PBLG triblock copolymer undergoing reversible thermal-induced organogelation is also presented. The changes in morphology are correlated, in both cases to the variations in molecular conformations of the polypeptide blocks.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P45 DPOLY: Surfaces, Interfaces, and Polymeric Thin Films - Surface Instabilities 159

8:00AM P45.00001 Buckling in a particle film, ANDREW CROLL, Department of Physics, North Dakota State University — When a thin rigid plate is adhered to a soft substrate and compressed, the plate will buckle out of plane to accommodate the applied stress. The out of plane bending is resisted by the substrate and the result is a sinusoidal topography (wrinkles). When the plate is replaced by a collection of closely packed particles similar phenomena results – the positions of the particles move out of plane and follow a roughly sinusoidal curve. Due to the similarity of the end state of each system, the same continuum theory is often applied to model the behaviour. Here, we use a carefully constructed experimental system consisting of micron-scale polymer and silica spheres on a PDMS elastomer substrate to demonstrate the physical differences between a continuum plate and a discrete set of particles. In particular, because we can easily track the position of each particle in three dimensions with confocal microscopy, we have access to all of the particle motion. We note that the wrinkling is independent of particle modulus, and highly dependent on particle packing. This leads us to suggest that the underlying physics is granular (and not continuum) in nature. This result may have implications in biology, where elastic continua are often made of discrete building blocks (e.g. cells).

8:12AM P45.00002 Defect induced shape instabilities in textured Membranes, DANIEL A. VEGA, Dep. of Physics, IFISUR, Univ. Nac. del Sur. Conicet, Argentina, MARCÉLO A. VILLAR, Dep. of Chem. Eng. PLAPIQUI, Univ. Nac. del Sur. Conicet, Argentina, ALDO D. PEZZUTTI, Dep. of Physics, IFISUR, Univ. Nac. del Sur. Conicet, Argentina — We study the dynamics of defect annihilation and quasi-equilibrium configurations in flexible textured membranes suffering a symmetry breaking phase transition. The phase separation process and relaxational properties are described through a Brazovskii-Helfrich-Canham Hamiltonian. Topological defects favor the development of local curvature to geometrically screen out the intrinsic stress field generated by the perturbations to the low symmetry phase. While in hexagonal systems the unbinding of dislocations and Carraro-Nelson interactions between disclinations slow down the dynamics, in smectic systems we found a wrinkled state where the bending forces are balanced by the out-of-plane hoop stretching generated by positive disclinations. The wrinkled configuration found in the smectic systems show features that resemble those found in flexible thin films under small external loads.

8:24AM P45.00003 Dewetting Dynamics from Polymer Interfaces, ANDREI FLUERASU¹, Brookhaven National Laboratory, LAURENCE LURIO², Department of Physics, Northern Illinois University, JYOTSANA LAL³, Argonne National Laboratory — The dewetting dynamics from metastable polymer/polymer interfaces is studied using X-ray Photon Correlation Spectroscopy (XPCS). In addition to more “usual” situations where XPCS correlation functions are used to measure out-of-plane height fluctuations (e.g. capillary waves), we show how this novel method can be used to measure in-situ in-plane motion of the dewetting film. The experimental correlation functions associated with this motion are fitted remarkably well by a simple model considering the growth of dewetting rims in the beam footprint.

8:36AM P45.00004 Nanoscale Confinement Induced Control of Polymer Thin Film Instabilities, DIYA BANDYOPADHYAY, ARVIND MODI, ALAMGIR KARIM, Department of Polymer Engineering, The University of Akron, Akron, OH 44325 — Control of stability and wettability of polymer thin films is invaluable to a range of functional coatings with applications from electronics to biomedical coatings, yet simple non-chemical modification strategies to accomplish this are generally lacking. We demonstrate a novel route to effectively control instabilities in model polystyrene films on partially wetting and non-wetting solid substrates that would otherwise lead to film dewetting. The method involves top down confining capillary force lithography at various length scales. Systematic experimental studies on silicon and silicon oxide substrates supported by analytical theory shows that for confining pattern wavelengths less than ~ 10 times film thickness, stabilizing surface tension forces dominate the overall energy balance of the system giving rise to stable films under confinement. Interestingly, thermal annealing at elevated temperatures after removal of confinement does not revert to growth of longer instability modes and stability of PS films is retained. These results pave the way for important new technological applications of otherwise unstable polymer films.

8:48AM P45.00005 The influence of the solid/liquid interface on the dewetting of ultra thin polymer films, MATTHIAS LESSEL, MISCHA KLOS, Experimental Physics, Saarland University, OLIVER BAEUMCHEN, Dept. of Physics & Astronomy, McMaster University, KARIN JACOBS, Experimental Physics, Saarland University — In recent years, many studies showed that a thin liquid film on a solid surface in air bears more complexity than expected from a simple three-layer-system: e.g. a highly mobile surface layer in case the liquid is an unentangled polystyrene (PS) melt (Yang et al., *Science* 2010; Seemann et al., *J. of Polym. Sci.* 2006) or the PS melt can slip over the solid substrate (Baumchen et al., *PRL* 2009). Our study focuses on such phenomena and explores their influence on dewetting (speed, morphology, etc.). We use hydrophilic and -phobic Si wafer (either covered by a highly ordered silane layer or by a thin layer of an amorphous fluoropolymer, AF 1600). On each of the substrates, one expects for a certain set of parameters spinodal dewetting for the PS melt. Yet experimentally, a much higher hole density is observed for both types of hydrophobic wafers than is theoretically expected. Moreover, the two hydrophobic coatings induce different dewetting speeds: the PS melt dewets faster on the silane covered Si wafer. The difference is attributed to slip (silane) or to no slip (AF 1600) conditions at the PS/substrate interface, which is also observable in the type of liquid front profile, which in turn changes the dewetting morphology.

9:00AM P45.00006 Viscoelastic properties of ultrathin polystyrene films by dewetting from liquid glycerol¹, JINHUA WANG, GREGORY MCKENNA, Department of Chemical Engineering, Texas Tech University, Lubbock, Texas, 79409 — There is considerable interest in studying the behaviors of polymers at the nanoscale. A liquid dewetting device originally proposed by Bodiguel and Fretigny^[1] was built in our lab to study the size effect on the viscoelastic behaviors of ultrathin polystyrene (PS) films. PS with molecular weight of 278 kg/mol and 984 kg/mol and various thermal treatments were examined. The glass transition temperature (T_g) reduction and film stiffening were observed in films less than 20 nm in thickness and the properties of ultrathin PS films are different from the bulk PS. The value of the plateau compliance changes linearly with film thickness. No molecular weight effect was found on the liquid dewetting behaviors of these PS films. Interestingly, even though the dewetting occurs on liquid glycerol, the apparent T_g reductions are less than observed in SiO₂ substrate supported films.

9:12AM P45.00007 Evolution of non-equilibrium entanglement networks in spincoat thin polymer films, KARI DALNOKI-VERESS, JOSHUA MCGRAW, PAUL FOWLER, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — Measuring the rheology of non-equilibrium thin polymer films has received significant attention recently. Experiments are typically performed on thin polymer films that inherit their structure from spin coating. While the results of several rheological experiments paint a clear picture, details of molecular configurations in spincoat polymer films are still unknown. Here we present the results of crazing measurements which demonstrate that the effective entanglement density of thin polymer films changes as a function of annealing toward a stable equilibrium value. The effective entanglement density plateaus with a time scale on the same order as the bulk reptation time.

9:24AM P45.00008 Evolution of Chitosan Film Thickness Profiles During Spincoating, CHRISTOPHER MURRAY, Lakehead University Orillia, MAXIMILIANO GIULIANI, JOHN DUTCHER, University of Guelph — Many hygroscopic biopolymers can be processed using aqueous solutions. For example, biopolymer films can be prepared by spincoating from dilute biopolymer solutions. We have spincoated ultrathin films of chitosan onto silicon substrates under controlled relative humidity (RH) using acetic acid solutions. Since the solvent is much less volatile than organic solvents that are typically used to spincoat thin films of synthetic polymers, the dynamics associated with the spincoating process can be several orders of magnitude slower. Because of the slow evaporation of the solvent, it is possible to control the thickness by controlling the RH value in the spincoating chamber. To gain insight into the spincoating process, we have collected images of the film during spincoating using a high-speed camera. This has allowed us to determine the evolution of the radial profile of the chitosan film thickness, which can be correlated with the final film thickness values measured using ellipsometry. We compare the measured film thickness profiles with those predicted by theoretical models of spincoating.

9:36AM P45.00009 Spreading of polymer droplets on thin polymer films, SARA L. CORMIER, JOSHUA D. MCGRAW, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — We present experimental results of small ($r \sim 10 \mu\text{m}$) polystyrene droplets spreading on thin polystyrene films. Previous experimental work has extensively explored droplets spreading on various types of solid substrates. However, to our knowledge, micron-sized liquid droplets spreading on the same liquid substrate have not been previously studied due to the difficulty of preparing such a geometry. Initially a glassy droplet is placed atop a glassy thin film and a distinct interface exists, upon heating the interface heals quickly. During spreading we must thus consider not only the flow of the polymer droplet but also that of the supporting film. This droplet-on-liquid geometry is fundamentally different from previous studies and allows us to probe the nanorheology of thin polymer films. We observe a characteristic power law spreading that is dependent on the size of the droplet as well as the height of the substrate film. The preparation and study of such samples provides many opportunities because the droplet and supporting film may be of the same polymer, the same polymer but differing molecular weight, or two different polymers.

9:48AM P45.00010 Experimental Study of Particle Behavior on a Curved Polymer Interface¹

KATHLEEN MCENNIS, CHUAN ZENG, BENNY DAVIDOVITCH, ANTHONY D. DINSMORE, THOMAS P. RUSSELL, University of Massachusetts Amherst — A spherical particle bound to an anisotropically curved liquid interface, such as a cylinder or catenoid, cannot maintain a constant contact angle without deforming the interface. Theory predicts that because of this deformation, individual particles will experience a capillary force toward lower negative Gaussian curvature. To test this prediction, particles are deposited from suspension onto interfaces of non-uniform shape. Melted polystyrene (PS) confined on chemically patterned surfaces creates semi-cylinders a few hundred microns in diameter. Microscopic catenoids are created by placing a melted PS film in an electric field. After cooling, PS vitrifies and the particles are frozen in place. The location of particles is observed by optical, scanning electron, and scanning force microscopy (SFM). Particles are observed to migrate to the rims of the catenoids while particles on semi-cylinders cluster, but show no preference for location. At these size scales and particle concentrations, the predicted single-particle behavior is not observed. SFM is used to determine the validity of the assumed constant contact angle boundary condition at the particle's surface. The implication of these results on curvature induced particle assembly will be discussed.

¹We acknowledge support from NSF-supported MRSEC on Polymers at UMass (DMR- 0820506), NSF CBET-0967620, and the U.S. DOE Office of Basic Energy Sciences (DE-FG02-96ER45612).

10:00AM P45.00011 Tension amplification in branched macromolecules

ALEXANDRU BACANU, JAMES BROCK, University of North Carolina at Chapel Hill, SERGEY PANYUKOV, P. N. Lebedev Physics Institute, MICHAEL RUBINSTEIN, University of North Carolina at Chapel Hill — A molecule's topology can greatly affect the distribution of tension within its bonds. Pom-pom molecules consist of a short linear spacer linking two star polymers, each containing z long arms. The striking ability of this molecular architecture to magnify spacer tension in solution by several orders of magnitude, from the pN to the nN level is due to the steric repulsion between densely packed side chains. In fact, the tension can increase to values that significantly alter the molecule's chemical properties, or even initiate the scission of a carbon-carbon covalent bond in the spacer chain. We study the tension distribution in the spacer and in side branches using molecular dynamics simulations and scaling theory. The dependences of observables such as spacer tension and root-mean-square spacer length on the number of side chains, chemical spacer length, and length of side branches have been quantified. Scaling models are used to explain the interrelated phenomena of tension amplification and spacer elongation and to interpret the results of molecular dynamics simulations.

10:12AM P45.00012 Viscous memory effects on the generation of hierarchical morphologies at an emulsified oil/water interface

MELANIE L. MORRIS, MICHAEL C. GROSS, ASMI PANIGRAHI, RYAN M. DEACON, PATRICK CHAN, JASON J. BENKOSKI, Johns Hopkins University Applied Physics Laboratory — A defining feature of biological materials is their fractal morphology. Cancellous bone, pulmonary alveoli, small intestine villi, neural networks, and bladder epithelium are just a few examples of biological structures with hierarchically organized topographies spanning multiple length scales. Herein we present a self-assembly method that faithfully reproduces the topographic features of these biomaterials. The system consists of a photocurable monomer and water. To this quasi-two-component system we add surfactants that sculpt the interface into the desired shape. The resulting structures are then solidified by crosslinking with UV light. Drawing from the rich phase behavior of oil/water/surfactant systems, we demonstrate complex fractal morphologies over many length scales ranging from several mm down to 100 nm. Quantitative image analysis reveals fractal morphologies with at least four distinct levels of hierarchy. Increasing viscosity, in particular, shows a strong correlation with the number of hierarchical levels.

10:24AM P45.00013 Effect of Molecular Architecture on the Wetting Properties of Polymers¹

EMMANOUIL GLYNOS, BRADLEY FRIEBERG, PETER GREEN, University of Michigan, Ann Arbor — We show that the wetting properties of star-shaped polystyrene (PS) macromolecules possessing sufficiently high functionality, f higher than 4, differ significantly from their linear analogues of otherwise identical chemical structure. The equilibrium contact angles of macroscopic droplets composed of star-shaped macromolecules on silicon oxide substrate, are as much as one order of magnitude smaller than their linear analogues, provided that f is equal to or greater than 8 and the degree of polymerization per arm length, N_{arm} , is sufficiently small. The corresponding line tensions of the star polymers are as much as two orders of magnitude smaller. The dewetting characteristics of the linear and star polymers also differ. Linear PS chains dewet leaving an adsorbed layer of nanoscopic dimensions; this layer is also structurally unstable and breaks up into nano-droplets, leaving a precursor layer at the boundary of the macroscopic droplets. The thickness of this layer is consistent with expectations based on the shape of the effective interface potential. The corresponding nanoscopic layer of star-shaped polymers, of sufficiently large f and sufficiently small N_{arm} , remains structurally stable. These effects are discussed in terms of the role of molecular architecture and entropic effects on the structure and dynamics of macromolecules at interfaces.

10:36AM P45.00014 Surface Segregation of Well-Defined Comb Polymers¹

BOXI LIU, RODERIC QUIRK, MARK FOSTER, The University of Akron, DAVID WU, Colorado School of Mines — Blending polymers with different chain architectures may prove useful in controlling interfacial properties by controlling interfacial segregation. A linear response theory by Wu *et al.* predicts that a long-chain branched polymer blended with its linear analog will be preferentially segregated to the surface and interface of the blend film. The comb architecture is particularly promising for achieving substantial surface segregation. In particular, its high degree of branching provides a substantial driving force for surface segregation when chain ends prefer the surface. Comb polystyrenes with well-defined architectural details were prepared by living anionic polymerization via the "grafting-through" approach. Neutron reflectivity (NR) and secondary ion mass spectrometry (SIMS) analyses reveal that the comb polymers that are still miscible with linear analogs in the bulk segregate so strongly to the surface that the surface concentration is nearly 100 vol%. The effect on the surface segregation of bulk concentration and chain end chemistry will be discussed.

10:48AM P45.00015 Size Dependent Nucleation of Confined 2-Decanol

SAMUEL AMANUEL, HILLARY BAUER, ALEXANDREA SAFIQ, JARGALSAIKHAN DULMAA, AMER KHRAISAT, Department of Physics and Astronomy, Union College, Schenectady, NY 12308, DEPARTMENT OF PHYSICS AND ASTRONOMY, UNION COLLEGE, SCHENECTADY, NY 12308 TEAM — We have studied freezing and melting of physically confined 2-decanol in nano porous silica using a Differential Scanning Calorimeter (DSC). Both melting and freezing temperatures are suppressed for physically confined 2-decanol. In the presence of bulk, freezing of the confined system is triggered by freezing of the bulk where nucleation is heterogeneous. There is, however, a cutoff size between 100 nm and 300 nm where phase transition is no longer initiated through heterogeneous nucleation. Below the cutoff size, nucleation is homogeneous where the confined system has to be supercooled further before any phase transition can occur. Melting of the confined system, on the other hand, is not influenced by the presence or absence of the bulk.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P46 DPOLY: Invited Session: DNA-Programmable Particle Assembly 160AB

8:00AM P46.00001 Self-Replication of Nanoscale tiles and patterns , PAUL CHAIKIN, New York University —

We want to make a “non-biological” system which can self-replicate. The idea is to design particles with specific and reversible and irreversible interactions, introduce seed motifs, and cycle the system in such a way that a copy is made. Repeating the cycle would double the number of offspring in each generation leading to exponential growth. Using the chemistry of DNA either on colloids or on DNA tiles makes the specific recognition part easy. In the case of DNA tiles we have in fact replicated the seed at least to the third generation. The DNA linkers can also be self-protected so that particles don't interact unless they are held together for sufficient time – a nano-contact glue. Chemical modification of the DNA allows us to permanently crosslink hybridized strands for irreversible bonds and a new type of photolithography. We have also designed and produced colloidal particles that use novel “lock and key” geometries to get specific and reversible physical interactions.

With Tong Wang, Ruojie Sha, Remi Dreyfus, Mirjam E. Leunissen, Corinna Maass, David J. Pine, and Nadrian C. Seeman.

8:36AM P46.00002 Inverse Problem in Self-assembly¹ , ALEXEI TKACHENKO, Brookhaven National Laboratory —

By decorating colloids and nanoparticles with DNA, one can introduce highly selective key-lock interactions between them. This leads to a new class of systems and problems in soft condensed matter physics. In particular, this opens a possibility to solve inverse problem in self-assembly: how to build an arbitrary desired structure with the bottom-up approach? I will present a theoretical and computational analysis of the hierarchical strategy in attacking this problem. It involves self-assembly of particular building blocks (“octopus particles”), that in turn would assemble into the target structure. On a conceptual level, our approach combines elements of three different brands of programmable self assembly: DNA nanotechnology, nanoparticle-DNA assemblies and patchy colloids. I will discuss the general design principles, theoretical and practical limitations of this approach, and illustrate them with our simulation results. Our crucial result is that not only it is possible to design a system that has a given nanostructure as a ground state, but one can also program and optimize the kinetic pathway for its self-assembly.

9:12AM P46.00003 Structural flexibility of DNA-Nanoparticle Assemblies¹ , DMYTRO NYKYPANCHUK, Brookhaven National Laboratory —

Encoding interactions between nanoparticles using DNA allows for creation of new classes of materials in which particles arrange in superlattices with the structure mainly defined by particle geometry and interactions between DNA shells. The phase behavior in these systems quite often can be rationalized using the interaction energy maximization argument for DNA provided key-lock recognition. However, a polymeric nature of DNA connections can bring about an unexpected phase behavior with structures typically not observed for non-directional interactions. In addition, DNA sensitivity to various specific and non-specific stimuli provides for precise lattice tunability within a given phase. We will provide several examples of phase change in systems of DNA interacting nanoparticles, where unusual, low dimensional structures form due to collective behavior of DNA chains. We will also discuss various ways to dynamically change superlattice parameters using physical variables such as electrostatic interactions or external osmotic pressure for continuous lattice tunability or using DNA machinery to program a step-wise change in the lattice parameter of the assemblies.

¹Research was supported by the U.S. DOE Office of Science and Office of Basic Energy Sciences under contract No. DE-AC-02-98CH10886.

9:48AM P46.00004 Nanoparticle Superlattice Engineering with DNA , CHAD MIRKIN, Northwestern University —

Recent developments in strategies for assembling nanomaterials have allowed us to draw a direct analogy between the assembly of solid state atomic lattices and the construction of nanoparticle superlattices. Herein, we present a set of six design rules for using DNA as a programmable linker to deliberately stabilize nine distinct colloidal crystal structures, with lattice parameters that are tailorable over the 25-150 nm size regime. These rules are analogous to those put forth by Pauling decades ago to explain the relative stability of lattices composed of atoms and small molecules. It is ideal to use DNA as a nanoscale bond to connect nanoparticles to achieve colloidal superlattice structures in this system, since its programmable nature allows for facile control over nanoparticle bond length and strength, and nanoparticle bond selectivity. This assembly method affords simultaneous and independent control over nanoparticle structure, crystallographic symmetry, and lattice parameters with nanometer scale precision. Further, we have developed a phase diagram that predicts the design parameters necessary to achieve a lattice with a given symmetry and lattice parameters a priori. The rules developed in this work present a major advance towards true materials by design, as they effectively separate the identity of a particle core (and thereby its physical properties) from the variables that control its assembly.

10:24AM P46.00005 Real-space crystallography and transformations of DNA-directed particle superlattices , JOHN CROCKER, University of Pennsylvania —

DNA is a versatile tool for directing the controlled self-assembly of nanoscopic and microscopic objects. The interactions between microspheres due to the hybridization of DNA strands grafted to their surface have been measured and can be modeled in detail, using well-known polymer physics and DNA thermodynamics. Knowledge of the potential, in turn, enables the exploration of the complex phase diagram and self-assembly kinetics in simulation. In experiment, at high densities of long grafted DNA strands, and temperatures where the binding is reversible, these system readily form colloidal crystals having a diverse range of symmetries. For interactions that favor alloying between two same-sized colloidal species, our experimental observations compare favorably to a simulation framework that predicts the equilibrium phase behavior, crystal growth kinetics and solid-solid transitions. We will discuss the crystallography of the novel alloy structures formed and address how particle size and heterogeneity affect nucleation and growth rates.

Wednesday, February 29, 2012 8:00AM - 11:00AM —

Session P47 DPOLY: Biopolymers: Molecules, Solutions, Networks, and Gels 160C

8:00AM P47.00001 Sub-nm porous membrane based on cyclic peptide nanotubes¹ , CHEN ZHANG, RAMI HOURANI, CHANGYI LI, University of California at Berkeley, BRETT HELMS, The Molecular Foundry, Lawrence Berkeley National Laboratory, TING XU, University of California at Berkeley —

Porous thin films containing subnanometer channels oriented normal to surface exhibit unique transport and separation properties and can serve as selective membranes for different applications. Generating flexible nanoporous films with densely packed vertical channels over large areas remains a significant challenge. We developed a new approach where the growth of cyclic peptide nanotubes can be directed in a structural framework set by the self-assembly of block copolymers. Conjugating polymers to cyclic peptides enables the nanotube subunits be selectively solubilized in one copolymer microdomain. Conjugated polymers mediate nanotube-polymer interaction to guide nanotube growth. This led to subnanometer porous membranes containing high-density arrays of through channels. In parallel, we also studied how to modify the interior of nanotubes with controlled geometry. Artificial amino acid is introduced in the primary sequence of cyclic peptide with a functional group presented in the nanotube interior without disrupting the high aspect ratio nanotubes. The new design of such a cyclic peptide enables one to modulate the nanotube growth process to be compatible with the polymer processing window, hence opening a viable way of fabricating polymeric membranes for different application

8:12AM P47.00002 Gel-on-Brush Model of Airway Surface of the Lung: its Predictive Role in Chronic Pulmonary Disease¹, LIHENG CAI, BRIAN BUTTON, CAMILLE EHRE, RICHARD BOUCHER, MICHAEL RUBINSTEIN, University of North Carolina at Chapel Hill — Clearance of mucus is the primary defense mechanism that protects airways from inhaled infectious and toxic agents. The current two-layer Gel-on-Liquid model in which a gel-like mucus is propelled on top of a “watery” periciliary layer (PCL) surrounding the cilia does not adequately describe efficient mucociliary clearance in health nor properly predict failure of mucus clearance in disease. We propose and provide evidence for a qualitatively different Gel-on-Brush model with a gel-like mucus layer in contact with a “brush-like” periciliary layer, composed of macromolecules tethered to the airway surface. The relative osmotic moduli of the mucus layer to the “brush-like” PCL layer explain both the stability of mucus clearance in health and its failure in airway disease. Our Gel-on-Brush model of airway surface layer opens important new directions for treatments of airway disease.

8:24AM P47.00003 Experimental and Computational Analysis of Structural and Mechanical Properties of Fibrin Gels, OLEG KIM, ZHILIANG XU, Department of Applied and Computational Mathematics and Statistics, University of Notre Dame, IN, ALISA WOLBERG, Department of Pathology and Laboratory Medicine, University of North Carolina, USA, ELLIOT ROSEN, Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, USA, MARK ALBER, Department of Applied and Computational Mathematics and Statistics, University of Notre Dame, IN. — An important area in coagulation research is the study of the structural stability of a blood clot, which has important medical consequences. The stability of clots is closely related to the fibrin networks, which provides the structural support for a blood clot. We synthesized, studied, and compared fibrin networks, with and without cells, formed under wild type and hemophilic conditions. The 3D structure of each fibrin network was reconstructed from z-stacks of 2D confocal microscopy sections by implementing novel image analysis algorithms. These 3D images were utilized to establish microstructure-based models for studying the relationship between the structural features and the mechanical properties of the fibrin networks. The mechanical properties were assessed by analyzing the networks' responses to uniaxial tensile and shear stresses, simulating the impact of blood flow on the fibrin network. We will show in this talk that the elasticity of the fiber network predicted by the model agrees well with prior experimental data for small networks. We will also show that a nonlinear worm-like chain model correctly predicts both the alignment of the fibers and the elastic properties of the networks as the clot sample is stretched.

8:36AM P47.00004 Block copolymer self-assembly for the responsive reinforcement of injectable protein hydrogels, M.J. GLASSMAN, Massachusetts Institute of Technology, S. LI, J. CHAN, California Institute of Technology, B.D. OLSEN, Massachusetts Institute of Technology — Shear-thinning injectable protein hydrogels are emerging as important biomaterials for the minimally-invasive implantation of scaffolds for tissue engineering and drug delivery. In this work, responsive block copolymer self-assembly is employed to trigger nanostructure formation in hydrogels made from artificial associative proteins, producing hydrogels with resistance to shear-thinning post injection, reduced erosion rate, higher toughness, and dramatically reduced creep compliance. Polymer-protein-polymer triblock copolymers have been synthesized by conjugating poly(N-isopropylacrylamide) to either end of a protein midblock decorated with self-associating pentavalent sticker domains. Self-assembly at elevated temperatures introduces a second physical network into the protein hydrogel with an independent and tunable relaxation time. The phase behavior of these dual-network hydrogels has been explored, revealing the ability to access nanostructured morphologies, and the effect of self-assembled polymer domains on the linear mechanics and toughness of injectable hydrogels has been investigated.

8:48AM P47.00005 Electrophoresis of DNA-protein conjugates: hydrodynamic end effects and electrostatic interactions, MYKYTA V. CHUBYNSKY, GARY W. SLATER, Department of Physics, University of Ottawa, Canada — DNA fragments can be separated by length in free solution by attaching them to neutral or positively charged “drag-tags” (e.g., proteins), a technique known as end-labeled free-solution electrophoresis (ELFSE). We first extend a previous theory of ELFSE for neutral drag-tags to the case of weakly charged drag-tags. The simplest variant of the theory assumes that all parts contribute equally to the mobility (no end effects) and that both the DNA and the drag-tag are fully flexible and do not interact. We analyze the influence of these assumptions. We obtain the exact (within the Kirkwood-Riseman approximation) form of the function describing the end effects for flexible polymers. The main significance of the end effects is the $N^{-3/4}$ (instead of N^{-1}) form of the correction to the mobility for large DNA lengths N . We also show that the end effects are weaker for semiflexible and stiff polymers. Using a simple model, we study how the conformation of the drag-tag changes due to the electrostatic interaction with the DNA and how this influences the mobility.

9:00AM P47.00006 The local dynamics of unfolded versus folded tRNA in comparison to synthetic polyelectrolytes and the role of electrostatic interactions, JOON HO ROH, University of Maryland and Johns Hopkins University, MADHU TYAGI, NIST Center for Neutron Research and University of Maryland, ROBERT M. BRIBER, University of Maryland, SARAH A. WOODSON, Johns Hopkins University, ALEXEI SOKOLOV, University of Tennessee — The local dynamics of RNA is strongly coupled to biological functions such as ligand recognition and catalysis. We have used quasielastic neutron scattering spectroscopy to follow the local motion of RNA and a synthetic polyelectrolyte as a function of Mg^{2+} concentration. We have observed that increasing Mg^{2+} concentration increases the picosecond to nanosecond dynamics of hydrated tRNA while stabilizing the tRNA folded structure. Analyses of the atomic mean-squared displacement, relaxation time, persistence length, and fraction of mobile atoms showed that unfolded tRNA is more rigid than in the folded state. This same behavior was observed for sulfonated polystyrene indicating that the increased dynamics in arises from charge screening of the polyelectrolyte rather than specific interactions. These results are opposite to what is observed for proteins for the relationship between the unfolded/folded states and the internal dynamics where the folded state is observed to be more rigid than the unfolded state. We conclude that the local dynamics for both bio- and synthetic polymers are strongly influenced by the electrostatic environment.

9:12AM P47.00007 Physical Structure of Methylcellulose Hydrogels, JOSEPH LOTT, JOHN MCALLISTER, SARA ARVIDSON, FRANK BATES, TIMOTHY LODGE, University of Minnesota — Methylcellulose (MC) is a chemically modified polysaccharide in which there is a partial substitution of hydroxyl groups with methoxy moieties. This results in a polymer that is water soluble at low temperatures and displays lower critical solution temperature (LCST) phase behavior at elevated temperatures. As such, aqueous solutions of MC have long been employed and studied due to their ability to form gels as temperature is increased. Currently, there is no consensus on the detailed mechanism of the gelation process, so a precise determination of the physical structure present in these materials may lead the way to new mechanistic understanding. Transmission electron microscopy (TEM) performed under cryogenic conditions is a powerful tool for the study of hydrogels as it allows direct imaging of the network while preserving the structure in the gel. Cryo-TEM investigations suggest that the hydrogel is composed of fibril-like aggregates comprising multiple polymer chains. Small-angle neutron scattering (SANS) provides a complimentary method to establish the detailed structure of the hydrogel network. We will report the effects of molecular weight, concentration, and temperature on the resultant physical structures within the gel.

9:24AM P47.00008 Mesoscopic Simulations of Free Solution Electrophoresis of Polyelectrolytes with Finite Debye Length, GARY SLATER, OWEN HICKEY, TYLER SHENDRUK, University of Ottawa — The mobility of charged oligomers results from a complex interplay between electrostatic and hydrodynamic interactions leading to a competition between counter-ion condensation and cooperative shearing within the diffuse layer. Simulations of polyelectrolytes that include explicit ions are computationally expensive, while algorithms that couple infinitely thin Debye layers to mesoscopic fluid models are only useful in the long chain limit because they fail to predict the rise and non-monotonicity of the mobility. We present a hybrid mesoscale simulation technique that utilizes multi-particle collision dynamics (MPCD) to simulate surrounding solvent molecules and the Debye-Hückel approximation to assign effective charge to the MPCD particles. This hybrid scheme can capture the electro-hydrodynamics without having to explicitly include counter-ions or make costly electrostatic calculations. This MPCD-MD Debye-Hückel method shows great potential for simulating electrophoretic behavior of polyelectrolytes in novel microfluidic devices.

9:36AM P47.00009 Interfacial adsorption and aggregation of amphiphilic proteins, DAVID CHEUNG, University of Warwick — The adsorption and aggregation on liquid interfaces of proteins is important in many biological contexts, such as the formation of aerial structures, immune response, and catalysis. Likewise the adsorption of proteins onto interfaces has applications in food technology, drug delivery, and in personal care products. As such there has been much interest in the study of a wide range of biomolecules at liquid interfaces. One class of proteins that has attracted particular attention are hydrophobins, small, fungal proteins with a distinct, amphiphilic surface structure. This makes these proteins highly surface active and they recently attracted much interest. In order to understand their potential applications a microscopic description of their interfacial and self-assembly is necessary and molecular simulation provides a powerful tool for providing this. In this presentation I will describe some recent work using coarse-grained molecular dynamics simulations to study the interfacial and aggregation behaviour of hydrophobins. Specifically this will present the calculation of their adsorption strength at oil-water and air-water interfaces, investigate the stability of hydrophobin aggregates in solution and their interaction with surfactants.

9:48AM P47.00010 Viscoelastic and poroelastic relaxations of polymer-loaded gels, EDWIN CHAN, National Institute of Standards and Technology, BLESSING DEEYAA, University of Maryland, PETER JOHNSON, CHRISTOPHER STAFFORD, National Institute of Standards and Technology — Gel layers are prevalent in many applications including water purification, fuel cells, tissue engineering and drug delivery. In these materials, their performance is closely linked to controlling transport of solutes such as solvent or polymer. Thus, understanding the critical time- and length-scale that regulate solute transport will enable development of membrane materials with the desired performance. In this contribution, we present the Poroelastic Indentation Relaxation (PRI) approach in quantifying the viscoelastic and poroelastic relaxations of geometrically-confined hydrogel layers. We demonstrate this indentation-based measurement approach in characterizing several materials properties including diffusion coefficient, shear modulus, and average pore dimensions of the hydrogel independent of the extent of geometric confinement. Additionally, we present a relaxation model that accounts for the viscoelastic and poroelastic contributions to the total relaxation process. Finally, we show that the PRI approach can quantify diffusion of solvent and polymer solution in a single test simply by changing the extent of deformation.

10:00AM P47.00011 Mechanical Characterization of Photo-crosslinkable Hydrogels with AFM¹, ALYSSA MCKENNA, Mount Holyoke College, MYUNGHWAN BYUN, RYAN HAYWARD, University of Massachusetts Amherst, KATHERINE AIDALA, Mount Holyoke College — Stimuli-responsive hydrogel films formed from photo-crosslinkable polymers are versatile materials for controlled drug delivery devices, three-dimensional micro-assemblies, and components in microfluidic systems. For such applications, it is important to understand both the mechanical properties and the dynamics responses of these materials. We describe the use of atomic force microscope (AFM) based indentation experiments to characterize the properties of poly(*N*-isopropylacrylamide) copolymer films, crosslinked by activation of pendent benzophenone units using ultraviolet light. In particular, we study how the elastic modulus of the material, determined using the Johnson, Kendall, and Roberts model, depends on UV dose, and simultaneously investigate stress relaxation in these materials in the context of viscoelastic and poroelastic relaxation models.

¹Support was provided by UMass Center on Polymers, DMR-0820506.

10:12AM P47.00012 Tough hydrogels from hydrophobically associating polymers¹, ROBERT WEISS, JINKUN HAO, University of Akron — Physical gels can be formed by interchain associations involving hydrophobic interactions. The viscoelastic and mechanical behavior of physically crosslinked copolymer hydrogels synthesized from *N*, *N*-dimethylacrylamide (DMA) and 2-(*N*-ethylperfluorooctane sulfonamido) ethyl acrylate (FOSA), with varying FOSA content, were studied by rheology and static tensile testing. The strong hydrophobic association of the FOSA moieties in an aqueous environment produced core-shell nanodomains (6 nm diameter) that provided the physical crosslinks. The PDMA-FOSA hydrogels exhibited excellent mechanical properties: modulus of 80 – 130 kPa, elongation at break of 1000 – 1600 %, tensile strength of 500 kPa, and toughness of 4 –6 MPa, depending on the FOSA concentration. The physical hydrogels were much more efficient at dissipating stress than the chemical hydrogels. Dynamic viscoelastic and stress relaxation experiments of the physical hydrogels and a chemically crosslinked PDMA hydrogel showed that the physical gel was more viscous than chemical gel and displayed much greater stress relaxation. That result was attributed to the extra energy dissipation mechanism provided by the reversible, hydrophobic crosslinks.

¹This research was partially supported by a grant from the Polymer Program of the National Science Foundation (Grant DMR- 0960461)

10:24AM P47.00013 Characterization of the Interfacial Adhesion for Responsive Hydrogels on Substrates, CHANDLER BENJAMIN, JOHN SPRINGMANN, SHAHZAD CHINDHY, WENDY CRONE, University of Wisconsin-Madison, CRONE LAB TEAM — In recent years a growing collection of responsive hydrogels have been developed which are capable of reversibly responding to a range of stimuli. These hydrogels operate in a hydrated environment and respond with significant volumetric reversible transformation through absorption or release of water within the polymeric network. Polymeric hydrogels in this class of shape memory materials have been successfully implemented in microfluidic and biomedical devices as components such as microchannels, micro-orifices, microvalves, micropumps and microcompressors. In practice, the hydrogel component is often polymerized on a substrate or within the confines of a channel in order to create responsive components. It is well known that the adhesion of a swelling hydrogel with its substrate varies with substrate properties. We show an experimental method to quantify the interfacial adhesion of responsive hydrogels with a substrate. This work provides a valuable method and theoretical basis for characterizing and optimizing the adhesion of responsive hydrogels.

10:36AM P47.00014 Resilient Synthetic PEG/PDMS Hydrogels Inspired by Natural Resilin¹, JUN CUI, MELISSA LACKEY, GREGORY TEW, ALFRED CROSBY, University of Massachusetts Amherst — Novel synthetic hydrogels are developed by incorporating hydrophobic polydimethylsiloxane (PDMS) into hydrophilic poly(ethylene glycol) (PEG)-based network using thiol-norbornene chemistry. The properties of these hydrogel are comparable to natural resilin, which is an elastic protein, existing in many insects, such as the tendons of flea and the wings of dragonfly, with extraordinary ability of mechanical energy storage. The energy storage efficiency (resilience) of the hydrogels is more than 97% even at tensile strains up to 170%. In addition, the Young's modulus of the hydrogels ranges from 3 kPa to 300 kPa by increasing the volume fraction of the PDMS in the network. These unique properties are attributed to the well-defined network and negligible secondary structure, provided by the versatile and efficient chemistry.

10:48AM P47.00015 pH-dependent and pH-independent self-assembling behavior of surfactant-like peptides, LEONID GUREVICH, PETER FOJAN, Aalborg University, BIOPHYSICS GROUP TEAM — Self-assembly of amphiphilic peptides designed during the last years by several research groups leads to a large variety of 3D-structures that already found applications in stabilization of large protein complexes, cell culturing systems etc. In this report, we present synthesis and characterization of two novel families of amphiphilic peptides KA_n and KA_nW ($n=6,5,4$) that exhibits clear charge separation controllable by pH of the environment. As the pH changes from acidic to basic, the charge on the ends of the peptide molecule varies eventually leading to reorganization of KA_n micelles and even micellar inversion. On contrary, the bulky geometry of the tryptophan residue in KA_nW limits the variation of the surfactant parameter and hence largely prevents assembly into spherical or cylindrical micelles while favouring flatter geometries. The studied short peptide families demonstrate formation of ordered aggregates with well-defined secondary structure from short unstructured peptides and provide a simple system where factors responsible for self-assembly can be singled out and studied one by one. The ability to control the shape and structure of peptide aggregates can provide basis for novel designer pH sensitive materials including drug delivery and controlled release systems.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P48 DPOLY: Focus Session: Crystallization in Single-, Multicomponent, and Hybrid Systems II 161

8:00AM P48.00001 Shear-induced homogeneous crystallisation in confined columns of polymer, JESSICA L. CARVALHO, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — In previous work, we have studied the crystallisation of a system of dewetted poly(ethylene oxide) (PEO) droplets. We have shown that this defect-free system nucleates homogeneously within the droplet volume. By capping this droplet system, a parallel plate geometry is obtained with the droplets forming isolated PEO columns (a capillary bridge) between the substrate and the cap. With this geometry we are able to investigate how the application of an oscillatory shear mediates the crystal nucleation step in small, defect-free volumes of material. These studies are typically carried out in bulk systems which are dominated by heterogeneous defects, here we will present our first results on the effect of shear on homogeneous nucleation.

8:12AM P48.00002 Chain Folding in Polymer Crystals Detected by Solid-state NMR¹, TOSHIKAZU MIYOSHI, The University of Akron — Polymer crystallization induces transitions from random coils in the melt states to bilayer structures consisting of chain-folded crystals and disordered amorphous regions. Although the concept of chain folding is well recognized, there have been continuous debates about adjacent re-entry fractions of polymer chains crystallized at different physical conditions. To understand chain-folding structures in complex systems, spatial selectivity to access short-range polymer-polymer interactions is necessary. In this talk, we will propose a novel approach using solid-state NMR and selective isotope labeling for characterizing chain-folding of polymer chains. Spatial selectivity in double quantum NMR reveals adjacent re-entry fractions in the bulk crystals at different conditions.

¹NSF-DMR1105829

8:24AM P48.00003 Forming hierarchically ordered hybrid materials using polymer crystallization, CHRISTOPHER LI, BIN DONG, TIAN ZHOU, WENDA WANG, Department of Materials Science and Engineering, Drexel University, Philadelphia, PA 19104 — Hierarchically ordered hybrid materials are of great interest for next generation advanced materials research. In this presentation, we will present our recent results on employing polymer single crystals (PSC) to template nanoparticle assembly, leading to hierarchically ordered hybrid materials. Tailor-made, free-standing NP frames and wires containing single or multiple types of NPs have been obtained by using an in-situ polymer crystallization method. End functionalized poly(ethylene oxide) and polycaprolactone single crystals were used as the templates. Gold and magnetite NPs were successfully patterned as evidenced by transmission electron microscopy experiments. Interaction between NPs, free polymer chain as well as PSC has been systematically monitored using Surface Plasmon Resonance. It has been found that NP-free polymer chain interaction holds the key to forming ordered NP patterns in solution.

8:36AM P48.00004 Understanding Molecular Epitaxial Mechanism of the γ -form Crystal and Chain Tilt in the α -form Single Crystal of Isotactic Polypropylene, YAN CAO, RYAN VAN HORN, GUOLIANG ZHANG, HAO-JAN SUN, The University of Akron, KWANG-UN JEONG, Chonbuk National University Jeonju, FINIZIA AURIEMMA, CLAUDIO DE ROSA, Università di Napoli "Federico II", BERNARD LOTZ, Institut Charles Sadron (CNRS-Université de Strasbourg), STEPHEN CHENG, The University of Akron — We attempt to investigate how the epitaxial domination of the crystal morphologies takes place in the γ -form of the chain-folded crystals using high molecular weight isotactic polypropylene (i-PP) samples with a controlled number of stereodefects. Two different morphologies were identified *via* transmission electron and atomic force microscopies (TEM and AFM). One is needle-like and the other is "flat". Based on the tilted selected area electron diffraction (SAED) results from TEM, the microscopic formation mechanism of the "needle" and "flat" morphology was discussed and it revealed that in the "flat" γ -form crystal, the initial α -form single crystal had to have a stem orientation tilted away from the thin film normal within the ac-plane around the b-axis. Elongated α_2 -form lath-like single crystals were grown from thin film melt at $T_x = 145^\circ\text{C} - 155^\circ\text{C}$ using commercial sample. SAED experimental results show that the stems in these lath-like single crystals were tilted at an unusual 17° angle around the b-axis. This 17° -stem tilt in the α_2 -form single crystals favors the $(10\bar{2})$ fold surface and appears to depend upon both conformational and chain folding constraints.

8:48AM P48.00005 Kinetic Control of the Halogen Distribution in Crystals of Precisely Substituted Polyethylenes, RUFINA ALAMO, PAPATYA KANER, CAROLINA RUIZ-ORTA, FAMU-FSU College of Engineering, Tallahassee, Florida 32312, EMINE BOZ, KENNETH B. WAGENER, University of Florida, Department of Chemistry, Gainesville, FL 32611 — Isothermally crystallized polyethylenes with precise chlorine substitution on each and every 21, 19, 15 or 9 backbone carbon display a drastic change in crystalline structure in a narrow interval of crystallization temperatures. The structural change occurs within one degree of undercooling and is accompanied by a change in WAXD patterns, a sharp increase in melting temperature, an increase in TG conformers and a decrease in SAXS periodicity. These changes correlate with a different distribution of Cl atoms in the crystallites. Under fast crystallization kinetics, the Cl distribution in the crystallites is disordered, while slower crystallization rates favor intermolecular staggering of chlorines and a herringbone structure. The drastic change in morphology is enabled by the precise halogen placement in the chain and driven by the selection of the nucleus stem in the initial stages of the crystallization. Exquisite kinetic control of the crystallization in novel polyolefins of this nature allows strategies for generating nanostructures at the lamellar and sub-lamellar level not feasible in classical branched polyethylenes.

9:00AM P48.00006 On the Width of the Crystallization Process, ANDREW OCHOA, MIRCEA CHIPARA, The University of Texas Pan American — Differential Scanning Calorimetry (DSC) is the most frequently used experimental techniques for the study of crystallization process in polymers and polymer-based nanocomposites. The experimental data are discussed within various theoretical approaches. Isothermal crystallization studies are typically discussed within the Avrami theory of phase change. However, the as recorded experimental data represent the time dependence of the derivative of the crystallinity degree (versus time) rather than the crystallinity degree. From the experimental point of view, the DSC parameters that are considered are the DSC peak position, the area under the DSC curve, and an empirical not very well defined onset temperature. However, all experimental data points are involved in the Avrami analysis after integration (in the Avrami analysis of the dependence representing the degree of crystallinity versus time). However, no effort has been done to understand the significance of the width of the as recorded DSC spectrum. A detailed analysis of the significance of the width of the DSC spectrum is presented. The connection between the width of the DSC spectrum and the exponent of the Avrami equation is analyzed in detail for the case in which nucleation is negligible. Tentatively, the as obtained results are extended to non-isothermal crystallization kinetics, recorded for various heating rates and to the Ozawa treatment of crystallization of polymers in non isothermal conditions.

9:12AM P48.00007 Crystallization and Ordering of Giant Molecules based on Nano-atoms, STEPHEN Z.D. CHENG, Department of Polymer Science, College of Polymer Science and Polymer Engineering, The University of Akron — To create new functional materials for advanced technologies, control over their hierarchical structures and orders is vital for obtaining the desired properties. We utilized and functionalized fullerene (C60) and polyhedral oligomeric silsesquioxane (POSS), and assembled these particles with polymers to form those hierarchical structures. The structures of these assemblies along with the resulting ordered structures were analyzed to determine their structure-property relationships. One of the most illustrating examples is a series of novel giant surfactants and lipids possessing a well-defined amphiphilic head and polymeric tails. Various architectures of this class of materials have been constructed and their self-assembly processes in solution, in the condensed bulk and thin films have been investigated. Another set of examples are “nano-atoms.” These classes of molecules are designed to possess features of molecular Janus particles with various symmetry breakings. When specific interactions are introduced, these “nano-atoms”: are functioned as building blocks to construct different amplified molecules and further to self-assemble into hierarchical ordered structures. Their thermodynamic phase diagrams and kinetic pathways are explored to understand this new class of materials and their potential applications in modern technologies.

9:48AM P48.00008 Morphologies in Semi-Crystalline Precise Acid- and Ion-Containing Polymers, KAREN WINEY, University of Pennsylvania — For over a decade we have endeavored to quantify the morphologies in ion-containing polymers using a combination of X-ray scattering and electron microscopy methods. We are motivated by the promise that when we know the polymer physics connecting chemical structure, nanoscale morphology, and physical properties, new strategies for improving polymer properties will be evident. This is particularly challenging in semi-crystalline polymers. Recently, we have been exploring the morphologies in precise acid copolymers and in the ionomers made neutralizing these precise copolymers. The precise copolymers are synthesized by Prof. K. Wagener's group at the University of Florida using acyclic diene metathesis and have functional groups attached to every 9th, 15th or 21st carbon along a linear polyethylene molecule. The precision of these molecules gives rise to well-defined hierarchical structures including acid-decorated polyethylene lamellae and acid or ionic aggregates arranged on cubic lattices. The temperature dependence of these polyethylene-based copolymers is dominated by the crystallization of the polymer. Stretching these materials can induce anisotropy that has facilitated our determination of these hierarchical morphologies and plans are underway to initiate in situ tensile deformation and X-ray scattering to probe the dynamic morphology.

10:24AM P48.00009 Nanohybrid shish kebab paper: Crystal growth and film properties¹, ERIC D. LAIRD, BING LI, SHAN CHENG, BIN DONG, RANJITA K. BOSE, KENNETH K.S. LAU, CHRISTOPHER Y. LI, Drexel University — Polyethylene single crystals were uniformly grown heterogeneously from carbon nanotubes (CNTs) in solution, forming the nanohybrid shish kebab (NHSK) structure. We demonstrate that highly uniform, free-standing nanohybrid buckypaper with high CNT contents (13-70%) could be produced from vacuum-filtrated polymer single crystal-decorated CNTs. In this way, polymer crystals served as unique spacers for CNTs so that uniform hybrid buckypaper films could be obtained without CNT agglomeration. Wetting techniques, thermal analysis, and scanning electron microscopy were used to elucidate the effect of polymer single crystals on the resultant structure. Surface roughness of NHSK paper could be controlled by tuning the polymer single crystal size (CNT separation distance). Superhydrophobic NHSK papers were obtained with high surface adhesion, which mimics the rose petal effect. Conductivity of the NHSK papers also varied with polymer crystal size. Great enhancement of important properties could be achieved through the formation of ternary hybrids. To that end, initiated- and oxidative chemical vapor deposition methods extend NHSK buckypaper applicability by providing functional polymer surfaces. NHSK papers may find applications in sensors, electrochemical devices and coatings.

10:36AM P48.00010 Role of lamellar thickness in the kinetics of polymer crystal growth¹, WENBING HU, State Key Laboratory of Coordination Chemistry, School of Chemistry and Chemical Engineering, Nanjing University — The lamellar thickness of polymer crystals reflects their thermodynamic metastability and meanwhile decides the linear crystal growth rates on their lateral sides. The traditional theories about the growth kinetics of polymer crystals, like Lauritzen-Hoffman theory and Sadler-Gilmer theory, attributed the effect of lamellar thickness to the free energy barrier at the lateral growth front, in order to explain the slower growth of thicker crystals observed at higher temperatures. We studied the linear growth rates of flat-on-oriented polymer crystals in ultra-thin films, by means of dynamic Monte Carlo simulations of lattice polymers. We found that at the same temperatures, the thicker crystals are actually growing faster. The effect of lamellar thickness has no relation with the free energy barrier; rather, it is only related with the driving force for crystal growth. On the basis of the intramolecular crystal nucleation model, we discussed a reasonable microscopic image on the growth kinetics of polymer crystals.

10:48AM P48.00011 Isothermal crystallization kinetics of Poly (lactic acid) studied by ultrafast chip calorimeter¹, JING JIANG, WEI JIANG, ZIJIE HUANG, DONGSHAN ZHOU, GI XUE, Nanjing University, DONGSHAN ZHOU TEAM — Poly (lactic acid) (PLA) is a biocompatible, biodegradable polymer which has attracted much attention. The crystallization ability, as one of the most factors influencing the physical properties of the biomaterials such as thermal, mechanical, and biodegradable properties, has been widely studied mainly by differential scanning calorimeters. However, although the crystallization of PLA is relatively slow, it's difficult to avoid the crystallization from the nuclei or the structure reorganization of the metastable crystalline formed during the annealing process when we use the normal DSC with the heating rate on the level of tens of K/min. With the chip calorimeter whose scanning rate can go up to 1000 K/s, we can avoid the structure reorganization of metastable crystalline during the heating. In this case we annealed the PLA sample in the 80-120°C temperature range and found the relationship between the onset the melting temperature T_m and crystallization temperature T_c is $T_m = 0.53T_c + 213.5$ and the equilibrium melting temperature is $T_{m,f} = 179.6^\circ\text{C}$.

Wednesday, February 29, 2012 8:00AM - 10:48AM –

Session P49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Interfaces and Contacts 162A

8:00AM P49.00001 Charge transfer and polarization at interfaces with conjugated molecules, NORBERT KOCH, HU-Berlin & HZB — The function and efficiency of organic electronic devices is determined to a significant extent by the electronic properties of organic/organic heterojunctions and interfaces between electrodes and organic semiconductors. The energy level alignment between metal electrodes and active organic layers can be adjusted over wide ranges by employing interlayers of strong molecular acceptors and donors that undergo charge transfer reactions with the metal. It will be shown that such interlayers lead to lower charge injection barriers than pristine metals, even when the work function is the same. It is argued that the molecularly modified electrodes are electronically more rigid than their pristine metal counterparts, i.e., the electron spill-out at the organic-terminated surface is less pronounced compared to metal surfaces. The energy levels at organic/organic heterojunctions comprising donors and acceptors as used in organic photovoltaic cells are essentially independent of deposition sequence, as long as supporting electrodes do not induce energy level pinning. When a high work function electrode is used, the energy levels may become Fermi-level pinned and an electric field drops right at the heterojunction. This effect is exemplified for the donor diindenoperylene and the acceptor C60. The electric field distribution within an organic opto-electronic device may thus be adjusted locally by employing interfacial energy level pinning, even at weakly interacting organic/organic interfaces.

8:36AM P49.00002 Tuning Contact Recombination and Open-Circuit Voltage in Polymer Solar Cells via Self-Assembled Monolayer Adsorption, HE WANG, ENRIQUE GOMEZ, Department of Chemical and Biological Engineering, Princeton University, ZELEI GUAN, Department of Electrical Engineering, Princeton University, CHERNO JAYE, DANIEL FISCHER, National Institute of Standards and Technology, ANTOINE KAHN, Department of Electrical Engineering, Princeton University, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — We adsorbed fluoro-alkyl and hydrogenated-alkyl phosphonic acid derivatives onto indium tin oxide (ITO) for forming self-assembled monolayers (FSAMs and HSAMs, respectively) to tune the open-circuit voltage (V_{oc}) of polymer solar cells. The adsorption of FSAM and HSAM alters the work function of ITO from 4.3 eV to 5.5 eV and 4.0 eV, respectively, as verified by ultraviolet photoemission spectroscopy. Polymer solar cells having FSAM-, HSAM-treated ITO, and bare ITO as anodes display V_{oc} of 0.58V, 0.48V, and 0.31V, respectively. Yet, the hole injection barrier from the anode to the active layer is the same for all three devices. Inverse photoemission spectroscopy measurements indicate that the energy barrier for minority carrier transport to the anode is largest for solar cells comprising FSAM-treated ITO and lowest for devices with bare ITO as anode. Since a high energy barrier for minority carrier transport results in lower contact recombination at the anode, it is this energy barrier that is responsible for differences in the V_{oc} s observed in polymer solar cells having anodes that have been pre-treated with SAMs.

8:48AM P49.00003 Electronic Structure of Organic-Metal Interfaces¹, SUNG-YOUNG HONG, PO-CHUN YEH, JERRY DADAP, RICHARD M. OSGOOD, Columbia University — Organic self-assembled monolayers (SAMs) are important to the understanding of molecular electronics as well as the study of charge transfer in photovoltaic applications. We use two-photon photoemission (2PPE) to investigate the interfacial electronic structure of SAMs on metals. In particular we study the unoccupied states of thiolates and fluorinated thiolates on Cu(111) as a function of molecular coverage using both monochromatic and time-resolved bichromatic 2PPE. While accurate measurements have been made on mostly full monolayer systems, similar effort on detailed coverage-dependence has not yet been reported. We track the formation of the interfacial dipole layer as well as the emergence of intermediate and final states vs. coverage.

¹Work is supported by DOE EFRC grant CU08-9796

9:00AM P49.00004 Fermi level pinning by integer charge transfer at electrode-organic semiconductor interfaces, DENIZ CAKIR, MENNO BOKDAM, GEERT BROCKS, University of Twente — The atomic structure of interfaces between conducting electrodes and molecular organic materials varies considerably. Yet experiments show that pinning of the Fermi level, which is observed at such interfaces, does not depend upon the structural details. In this work [1], we develop a general model to explain Fermi level pinning, and formulate simple expressions for the pinning levels, based upon integer charge transfer between the conductor and the molecular layer. In particular, we show that DFT calculations give good values for the pinning levels.

[1] Appl. Phys. Lett 98, 113303 (2011).

9:12AM P49.00005 Analysis of interface states in blend of polythiophene and polyselenophene: experiments and theory, HELENE ANTAYA, MACIEJ SAKOWICZ, CARLOS SILVA, MICHEL COTE, University of Montreal — Organic photovoltaic devices are presently the subject of intense research since they could eventually propose solar energy solutions at a much reduced cost compared to inorganic devices. Presently, electron transport in organic photovoltaic devices is achieved with a fullerene derivative (PCBM) but this solution has some disadvantages. First, the ratio of PCBM to polymer has to be quite high to assume good electronic transport, and second, the relatively high cost of PCBM is not ideal with the goal to reduce the cost of the device. For these reasons, a replacement for PCBM is desirable and an all polymer device solution is viewed as the best avenue. Since polythiophene (P3HT) is ideal for hole transport, its isovalent polyselenophene (P3HS) where sulfur atoms are replaced with selenium atoms might offer an interesting alternative to PCBM. The physical processes in organic devices are quite different from those of inorganic devices. Charge separation in organic devices is achieved by forming an interface between two organic materials with type 2 level alignment. However, because of the large binding energies observed in organic compounds, there is often the presence of H-aggregate states at the junction between the two organic materials. In this presentation, we will report the results of interface states in a blend of polythiophene and polyselenophene. Photoluminescence spectra will be presented along with calculations of these states with the help of the time-dependent density-functional theory.

9:24AM P49.00006 Controlling Side Chain Density of Electron Donating Polymers for Improving V_{OC} in Polymer Solar Cells, B.J. KIM, K.H. KIM, C.H. CHO, H. KANG, KAIST, S.C. YOON, KRIST — The ability to tune the LUMO/HOMO levels of electroactive materials in active layer of polymer solar cells is critical in controlling their optical and electrochemical properties because the HOMO and LUMO offsets between the polymer donor and the electron acceptor strongly affect charge separation and the open circuit voltage (V_{OC}) of a solar cell. Here, we developed two series of electroactive materials for improving V_{OC} in polymer solar cells. First, we enable facile control over the number of solubilizing groups ultimately tethered to the fullerene by tuning the molar ratio between reactants from 1:1 to 1:3, thus producing *o*-xylenyl C₆₀ mono-, bis-, and tris-adducts (OXCMA, OXCBA, and OXCTA) as electron acceptors with different LUMO levels. As the number of solubilizing groups increased, V_{OC} values of the P3HT-based BHJ solar cells increased from 0.63, 0.83, to 0.98 V. Second, we present a series of novel poly[3-(4-*n*-octyl)phenylthiophene] (POPT) derivatives (POPT, POPTT, and POTQT) as electron donors with different side-chain density. As a result of lower HOMO levels by decrease in the side-chain density of the polymers, the devices consisting of POPT, POPTT, and POTQT with PCBM showed increased V_{OC} values of 0.58, 0.63, and 0.75 V, respectively.

9:36AM P49.00007 Charge Injection Mechanism at Carbon Nanotube-Organic Semiconductor Interface¹, BIDDUT K. SARKER, Nanoscience Technology Center and Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, Department of Physics, and School of Electrical Engineering and Computer Science, University of Central Florida — One of the major challenges in the fabrication of high performance organic electronic devices is to overcome the inefficient charge injection from metal electrodes into organic semiconductors caused by large interfacial contact barrier. One potential key step of improving the charge injection is to employ single-walled carbon nanotubes as electrodes. Towards this end, we fabricated pentacene field effect transistor using densely aligned carbon nanotube array electrodes with open-ended and parallel tips. The room temperature electronic transport measurements of the devices show excellent transistor properties with field effect mobility of up to 0.65 cm²/Vs and current on-off ratio of up to 1.7×10⁶, which are higher than that of the control devices fabricated with gold electrodes. The high-performance of the devices is attributed to lower charge injection barrier at carbon nanotubes and pentacene interface. In order to find the direct evidence of the low injection barrier, we carry out low temperature electron transport measurement of our devices. We will present the detailed analysis of the low temperature data.

9:48AM P49.00008 Does Organic Field Effect Transistors (OFETs) Device Performance using Single-walled Carbon Nanotubes (SWNTs) Depend on the Density of SWNT in the Electrode?¹, NARAE KANG, BIDDUT K. SARKER, Nanoscience Technology Center, and Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, and Department of Physics, and School of Electrical Engineering and Computer Science, University of Central Florida, — Carbon nanotubes as an electrode material for organic field effect transistors (OFETs) have attracted significant attention. One open question is that whether the density of the Single-walled carbon nanotubes (SWNTs) in the electrode has any influence in the device performance of OFETs. In order to address this issue, we fabricated OFETs using SWNT aligned array electrode, where we varied the linear density of the nanotubes in the array of the electrodes during dielectrophoretic assembly of high quality surfactant free and stable aqueous SWNT solution. The source and drain of SWNT electrodes have been formed by electron beam lithography (EBL) and oxygen plasma etching. The OFETs were fabricated by depositing a thin film of poly (3-hexylthiophene) on the SWNT electrodes. We will present detailed result of our study.

10:00AM P49.00009 Work function recovery of air exposed molybdenum oxide thin films with vacuum annealing, IRFAN IRFAN, University of Rochester, ALEXANDER TURNISKE, University of Wisconsin, ZHENAN BAO, Stanford University, YONGLI GAO, University of Rochester — We report substantial work function (WF) recovery of air exposed molybdenum oxide thin films with vacuum annealing. The high WF (~6.8 eV) of thermally evaporated MoO_x thin film was observed to decrease sharply to ~5.6 eV with an air exposure of one hour. The drop in the WF was accompanied with a very thin layer of oxygen rich adsorbate on the MoO_x film. The WF of the exposed MoO_x film started to gradually recover with increasing annealing temperature in a vacuum chamber having base pressure of 8 × 10⁻¹¹ torr. The saturation in the WF recovery was observed around 460 °C, with WF ~6.4 eV. The adsorb layer was found to be removed after the vacuum annealing. We further studied the interface formation between the annealed MoO_x and copper phthalocyanine (CuPc). The highest occupied molecular orbital (HOMO) level of CuPc was observed to be almost pinned to the Fermi level, strongly suggesting an efficient hole injection through the vacuum annealed MoO_x film.

10:12AM P49.00010 Ab-initio calculation of energy level alignment and vacuum level shift at CuPc/C60 interfaces¹, NA SAI, XIAOYANG ZHU, JAMES CHELIKOWSKY, University of Texas at Austin, KEVIN LEUNG, Sandia National Laboratory — The alignment of the donor and acceptor energy levels is of crucial importance for organic photovoltaic performance. We investigate the interfacial electronic structure and energy level alignment of copper phthalocyanine (CuPc)/fullerene (C60) using ab-initio density functional theory calculations including van der Waals interactions and hybrid density functionals. We show that energy level alignment critically depends on the standing-up and lying-down orientation of the CuPc molecules relative to C60 at the interface. We calculate the magnitude of the interface dipole at different molecular orientations and compare them to the vacuum level shift observed in photoemission spectroscopy. The validity of existing theoretical models which invoke charge transfer on this organic interface will be discussed in light of our predictions. Sandia National Laboratories is a multiprogram laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

¹This work is supported as part of the program “Understanding charge separation and transfer at interfaces in energy materials”, an Energy Frontier Research Center funded by the U.S. DOE Office of Basic Energy Sciences under Award number DE-SC0001091.

10:24AM P49.00011 Solution based cathode deposition for polymer light emitting devices, MARIAN TZOLOV, STEPHEN SWIONTEK, Department of Physics, Lock Haven University of PA — We report on a method for deposition of cathodes for polymer light-emitting devices (PLEDs), which is fundamentally different than the widely used thermal evaporation of metals. The thermal evaporation is well established in the industry but is very different than the solution processing of the rest of the PLEDs. It requires much more sophisticated equipment and much longer processing time than the solution processing. The metal evaporation requires temperatures around 1000°C with all following requirements for materials handling. Proposing a method alternative to the already well-established thermal evaporation technique is a challenging task, and we are demonstrating only the principal feasibility of a solution based deposition of the cathodes. It is based on electroless deposition of silver. The process is compatible with the solution processing of the rest of the device and allows to finalize the entire device using solution based processes. We demonstrate the most representative current-voltage characteristics, emission spectra, stability tests, and microstructure of the newly developed electrode. These initial experiments demonstrate the feasibility of the proposed method and point avenues for further improvement.

10:36AM P49.00012 Organic solar cells: How can the theory guide the experience?, NICOLAS BERUBE, VINCENT GOSSELIN, HUGO LEPAGE, MICHEL COTE, Universite de Montreal — Research in organic photovoltaic applications are receiving a great interest in the last few years as they offer an environmentally clean and low-cost solution to the world's rising energy needs. One of the main problems limiting the efficiency of an organic solar cell device is the strong binding energy of the excitons, typically of a few hundreds of meV, which is ten to one hundred times more than in inorganic devices. Another limiting factor, persistent in P3HT:PCBM devices, can be the misalignment of the the HOMO (Highest Occupied Molecular Orbital) and the LUMO (Lowest Unoccupied Molecular Orbital) energy levels of the different components of the solar cell. Scharber's model (Scharber, M.C., Adv. Mater. 18, 789) is a simple yet interesting approach for predicting the efficiency of those devices, mainly based on the values of the HOMO and the LUMO and reasonable assumptions for the exciton binding energy. In this presentation, we will discuss how theoretical calculations based on density-functional theory can provide a guide to find promising polymers for photovoltaic cells. The accuracy, limits and possible expansions of Scharber's model will be examined, and a number of interesting polymer candidates to reach and perhaps break the well-known 10 % efficiency will be presented.

Wednesday, February 29, 2012 8:00AM - 11:00AM –

Session P50 DPOLY: Focus Session: Dynamics of Polymers: Phenomena due to Confinement; Glass Transition 162B

8:00AM P50.00001 Theoretical prospects for understanding the glass transition in polymer thin films, SCOTT MILNER, Penn State University — Observations of confinement effects on the glass transition in thin polymer films remain vexing to theorists. Many experiments at sufficiently low frequencies consistently find that the free surfaces of many polymer films, whether freely suspended or supported, have anomalously low glass transition temperatures. This surface effect appears to be independent of molecular weight, and persists 10-20nm into the film. In contrast, freely suspended films have been observed by ellipsometry and other bulk-sensitive techniques to have anomalously low film-averaged T_g values, depending strongly on both film thickness and molecular weight for Mw above about 4×10^5 g/mol. The dependence on Mw persists to astonishingly large values ($\sim 10^7$ g/mol). Recent work of Pye and Roth strongly suggests the presence of two distinct mechanisms in these films, one operative at the free surface and Mw-independent, one depending on Mw and giving a weak second glass transition at considerably lower temperatures. In this talk, I will review the status of various theoretical proposals we have explored for explaining some of these disparate phenomena, including the effects of interrupted percolation at the free surface and the “sliding mechanism” originally suggested by de Gennes for Mw-dependent lowering of T_g . I will describe the present prospects for a successful theory, as well as suggest some potentially helpful experiments and analysis.

8:36AM P50.00002 Cooperative Length Scale and Fragility of Polystyrene under Confinement, CHUAN ZHANG, YUNLONG GUO, RODNEY PRIESTLEY, Princeton University — While thin films are an attractive model system to investigate the impact of confinement on glassy behavior, extending studies beyond thin films to geometries of higher dimensionalities is vital from both scientific and technological viewpoints. In this talk, we present the impact of confinement on the characteristic length at the glass transition as well as the fragility for confined polystyrene (PS) nanoparticles under isochoric conditions. We measure the glass transition temperature (T_g), fictive temperature (T_f) and isochoric heat capacity of silica-capped PS nanoparticles as a function of diameter via differential scanning calorimetry. From the measurement of T_f , we obtain the isochoric fragility, and via the fluctuation formula, the characteristic length at the glass transition. We illustrate that confinement under isochoric conditions for PS nanoparticles leads to a significant increase in the isochoric fragility while the characteristic length is reduced with size. At the minimum the results demonstrate a relationship between fragility and the characteristic length of isochorically-confined polymer that is not intuitive from the Adam-Gibbs theory.

8:48AM P50.00003 Impact of systematic chain architecture changes on the glass transition and modulus of thin polymer films, BRYAN VOGT, University of Akron, JESSICA TORRES, Intel, CHRISTOPHER STAFFORD, NIST, RICHARD REGISTER, Princeton University, DAVID UHRIG, Oak Ridge National Laboratory — We will discuss two systems that significantly impact the thin film behavior with minor changes in chemistry and chain architecture. First, two polymers based on 5-(2-phenylethyl)norbornene are examined. Depending on the polymerization route chosen, the resulting polymer backbone is comprised of either bicyclic (norbornyl) units, which leads to a relatively rigid polymer with a high bulk T_g , or monocyclic (cyclopentyl) units, which leads to a more flexible structure with a lower bulk T_g . The modulus and T_g of the rigid bicyclic polymer is thickness independent down to <10 nm, whereas the modulus of the more flexible monocyclic polymer decreases with decreasing thickness. By hydrogenation of the pendant phenyl ring to the cyclohexyl counterpart, we illustrate that minor changes in the relative flexibility of the side chain do not impact the observed thin film behavior. Second, a series of polystyrene with controlled branching including linear, comb, 6-arm star and centipede. Based upon the molecular mass of the arms, the comb polymer has a significantly larger persistence length and interestingly exhibits only a modest decrease in T_g (9 K) at 5 nm, while the moduli is thickness independent.

9:00AM P50.00004 A Direct Relationship between Enhanced Surface Mobility and Tg Reduction in Thin Polymer Films, ZAHRA FAKHRAAI, Department of Chemistry, University of Pennsylvania, JAMES A. FORREST, DONGPING QI, Department of Physics and Astronomy, University of Waterloo — Cooling rate dependent Tg measurements of thin polymer films show a strong correlation between the cooling rate and the confinement effects. It is observed that the Tg is more strongly dependent on the cooling rate as the film thickness is decreased. The confinement effects also become weaker at higher cooling rates and it appears that both for thick films and high cooling rates the confinement effect vanishes. The results can be plotted on an Arrhenius plot by assuming that the cooling rate is inversely related to the relaxation time as the temperature that the system falls out of equilibrium (Tg). The surface relaxation times can be independently measured using nano-hole relaxation and nanoparticle embedding techniques and the results can be plotted on the same Arrhenius plot. It is observed that the surface relaxation has much weaker temperature dependence, with an activation energy that matches the limit of zero film thickness for the rate-dependent Tg measurements. The strong correlation between surface properties obtained by direct mechanical measurements with the Tg measurements obtained by ellipsometry suggest that these two phenomena are from the same origin and one cannot be explained without the other.

9:12AM P50.00005 Reduced Glass Transition Temperatures of Thin Polymer Films - Confinement Effect or Artifact?, OLIVER BAEUMCHEN, JOSHUA D. MCGRAW, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1, JAMES A. FORREST, Department of Physics and Astronomy and Guelph-Waterloo Physics Institute, University of Waterloo, Waterloo, ON, Canada, N2L 3G1, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — For two decades there have been reports of measurements of reduced glass transition temperatures (T_g) in polymer, and in particular poly-styrene, films. These results have motivated theoretical models and a variety of sophisticated experiments probing interfacial polymer properties. While the much larger reductions in T_g for free standing films have suggested the importance of the free surface, a significant concern has been raised about a possible correlation between anomalous dynamics and incomplete equilibration of the sample. Here, we present new ellipsometry measurements which unambiguously address this concern. The glass transition in free standing and supported films can be changed by many 10's of degrees by manipulating the interfacial properties. Taken together with previous work the results clearly reveal the importance of free interfaces as we transition from two, to one, to zero free interfaces.

9:24AM P50.00006 Confinement in thin polymer films near Tg leads to factors of 10 to 1000 reductions in dye translational diffusion, JOHN TORKELOSON, HUI DENG, MANISH MUNDRA, Northwestern University — A breakthrough time/fluorescence resonance energy transfer method is used to measure out-of-plane translational diffusion coefficients of small-molecule dyes in thin polymer films near the glass transition temperature, Tg. The bulk translational diffusion coefficient is a strong function of dye size, increasing by a factor of 100 in polystyrene when dye molecular volume decreases by 25%. Reduction in PS film thickness below 500 nm leads to a factor of 1000 decrease in Disperse Red 1 diffusion coefficient while reduction below 140 nm leads to slightly more than a factor of 10 decrease in decacyclene diffusion coefficient. At a thickness less than 100 nm, the diffusion coefficients for the two dyes are identical within error. Similar effects have been observed in poly(methyl methacrylate) and polysulfone films at $T_g + 3$ K. These effects are not directly correlated with the Tg-confinement effect in these polymers as the length scales for confinement effects are much smaller in the case of Tg and in some of the polymers both diffusivity and Tg decrease with confinement.

9:36AM P50.00007 Measuring the glass transition of polymer nanodroplets, CHAD DALEY, JAMES FORREST, University of Waterloo — Despite almost 2 decades of measuring the glass transition temperature (T_g) in thin polymer films, there is no consensus on the magnitude (or even the existence) of observed T_g reductions. Recent suggestions that reduced T_g values in thin polystyrene films may be nothing more than a complicated artifact of sample preparation must be taken very seriously. Reduced T_g values are reported only for polymer films prepared on a non-wetting substrate where the film is unstable with respect to dewetting. In all cases only kinetic metastability allows one to measure a T_g value. The fundamental problem is that an unambiguous measure of T_g can only be obtained as the sample is cooled from the equilibrium liquid. No experiments involving thin polymer films have yet satisfied this condition. Our approach is to use samples prepared in the equilibrium state atop a non-wetting substrate (a collection of spherical caps). Since the droplets are already in the equilibrium state, they can be annealed for arbitrarily large times without evolution of the structure. We describe dilatometric measurements of T_g for nanometer sized spherical caps of polystyrene. This technique can be used to investigate the effect of annealing history and to extend the studies of T_g in high surface area to volume systems beyond polymers and into other molecular glass forming materials.

9:48AM P50.00008 Molecular motion in polymer thin films exhibits fast and slow subpopulations., KEEWOOK PAENG, MARK EDIGER, University of Wisconsin-Madison — The reorientation of dilute fluorescent probes in thin polymer films was studied using a photobleaching technique. The existence of two subsets of probe molecules with different dynamics was revealed by temperature-ramping and isothermal anisotropy measurements. For freestanding polystyrene films, the slow subset shows bulk-like dynamics while the more mobile subset reorients 4 orders of magnitude faster at $T_g - 5$ K. The difference in dynamics becomes larger as temperature decreases and disappears as temperature approaches T_g . We interpret the fraction of the sample with fast dynamics as a high mobility layer at the film surfaces. The thickness of this mobile surface layer increases with temperature and does not depend on the molecular weight of the polymer and total film thickness. The mobile surface layer exists in various freestanding polymer thin films including polystyrene and poly(methyl methacrylate) and is also present in supported films of these polymers.

10:00AM P50.00009 Confinement Effects of Neighboring Polymer Domains on the T_g s of Infinitely Dilute Blend Components and Ultrathin Film Layers, CHRISTOPHER EVANS, ROBERT SANDOVAL, JOHN TORKELSON, Northwestern University — Using fluorescence, we study the glass transition temperature (T_g) of a polymer species near the limit of infinite dilution. In blends with very dilute polystyrene (PS), intrinsic (unlabeled) and extrinsic dye-labeled fluorescence exhibit quantitative agreement for PS component T_g s. Dilute (0.1 wt%) PS T_g is strongly perturbed towards the matrix T_g ; e.g., 38 C in PnBMA and 119 C in PMMA. These dilute component T_g s yield a range of self-concentrations (0.18-0.47) in the framework of the Lodge-McLeish model. We also study multilayer, nanoconfined films with neighboring polymer domains by fluorescence. For PS supported on a bulk underlayer, the T_g of sub-100 nm PS is perturbed towards the underlayer T_g . For example, the 45 C T_g of a 14-nm PS layer on bulk PnBMA approaches the T_g for 0.1 wt% PS in PnBMA. These results underscore the role of neighboring polymer domains on the dynamics of an infinitely dilute species or an ultrathin polymer film layer and indicate that T_g -confinement effects in blends and thin films can be viewed as variations of the same physical phenomenon.

10:12AM P50.00010 Molecular Weight Dependent and Independent Glass Transition Temperature Reductions Coexisting in High MW Free-Standing Polystyrene Films, JUSTIN PYE, CONNIE ROTH, Dept of Physics, Emory University — Using transmission ellipsometry, we have measured the thermal expansion of ultrathin, high molecular weight (MW), free-standing polystyrene films over an extended temperature range. For two different MWs, we observed two distinct reduced glass transition temperatures (T_g s), separated by up to 60 K, within single films with thicknesses h less than 70 nm. The lower transition follows the previously seen MW dependent, linear $T_g(h)$ behavior, while we also observe the presence of a much stronger upper transition that is MW independent and exhibits the same $T_g(h)$ dependence as supported and low MW free-standing films. This represents the first experimental evidence indicating that two separate mechanisms can act simultaneously on thin free-standing polymer films to propagate enhanced mobility from the free surface into the material. The change in thermal expansion through the transitions indicate that $\sim 90\%$ of the film (matrix) solidifies at the upper transition with only $\sim 10\%$ of the material remaining mobile, freezing in at the lower transition. Surprisingly, when we compare our results to the existing literature, and especially the low MW free-standing film data, we conclude that the upper transition encompasses the free surface region and associated gradient in dynamics. This leaves open the question about where the small ($\sim 10\%$) fraction of material that has ultrafast, MW dependent dynamics resides within the film.

10:24AM P50.00011 Glass Transition and Physical Aging in Thin Polymer Films: A Unified Picture of Confinement, CONNIE ROTH, Dept. of Physics, Emory University — The effect of confinement on the glass transition, structural relaxation, and other material properties has garnered a great deal of attention during the past two decades. Despite the common misperception, there is considerably more agreement than disagreement (or "controversy") of the phenomena in the existing literature. This talk will summarize current experimental findings in the field, focusing on the author's recent work that links physical aging in thin polymer films to T_g changes near a free surface. We also demonstrate that the intricate molecular weight dependence of the film thickness dependent T_g reductions in free-standing films result from two separate mechanisms acting simultaneously on the films. From these results a universal picture is starting to emerge with some effects common to colloidal and small molecule glasses as well.

Wednesday, February 29, 2012 8:00AM - 11:00AM —

Session P51 DCMP DFD: Colloids III: Shear and Hydrodynamics Boston Convention Center 154

8:00AM P51.00001 Confined colloidal suspensions under simple shear, XINLIANG XU, STUART RICE, AARON DINNER, James Franck Institute, University of Chicago — Here we report a study of a simple model system, a colloidal suspension of near hard spheres in an otherwise Newtonian fluid using Stokesian Dynamics (SD) simulations in combination with Non-Equilibrium Umbrella Sampling (NEUS) techniques. The suspension is confined by an external potential in the y direction and is driven far out of equilibrium with a simple shear flow. At moderate shear rate, the suspension forms layers normal to the flow gradient direction, in contrast to equilibrium. In addition to that, novel anisotropic structures (strings in vorticity direction at low density for example) are observed within each layer. We use Non-Equilibrium Umbrella Sampling to explore the relationship between this string structure and the strength of the layer formation. Furthermore we have also studied the relationship between the non-Newtonian behavior of the suspension and the strength of the layer structure.

8:12AM P51.00002 The nonlinear structural response of colloidal suspensions under large amplitude oscillatory shear, NEIL Y.C. LIN, XIANG CHENG, ITAI COHEN, Physics Department, Cornell University — When a colloidal suspension is under oscillatory shear, the particle configuration has a flow-induced anisotropy. While these structural rearrangements have been intensively studied in the linear regime where the amplitude of the applied shear is small, the nonlinear structural response of suspensions under large amplitude oscillatory shear is poorly understood. Using a shear cell coupled to a fast confocal microscope, we directly measured the microscopic structure of colloidal suspensions under large amplitude oscillatory shear. To quantify the structural response, we integrated the pair correlation function over all contact positions; this quantity is proportional to the entropic stress of the suspension. We investigated the structural/stress response of colloidal suspensions systematically with increasing shear amplitudes. We observed strong nonlinear responses in both dense and dilute suspensions under large amplitude oscillatory shear. At even higher amplitudes, we found an overshoot of the stress response in dense suspensions. Our results provide insight on the microscopic structural origin of the nonlinear response of sheared colloidal suspensions.

8:24AM P51.00003 Imaging the microscopic structure of shear thinning and thickening colloidal suspensions, XIANG CHENG, Cornell University, JONATHAN MCCOY, Colby College, JACOB ISRAELACHVILI, University of California Santa Barbara, ITAI COHEN, Cornell University — The viscosity of colloidal suspensions can vary by orders of magnitude depending on how quickly they are sheared. Although this non-Newtonian behavior is believed to arise from the arrangement of suspended particles and their mutual interactions, microscopic particle dynamics in such suspensions are difficult to measure directly. Here, by combining fast confocal microscopy with simultaneous force measurements, we systematically investigate a suspension's structure as it transitions through regimes of different flow signatures. Our measurements of the microscopic single-particle dynamics unambiguously show that shear thinning results from the decreased relative contribution of entropic forces and that shear thickening arises from particle clustering induced by inter-particle hydrodynamic lubrication forces. Furthermore, we explore out-of-equilibrium structures of sheared colloidal suspensions and report a novel string phase, where particles link into log-rolling strings normal to the plane of shear. Our techniques illustrate an approach that complements current methods for determining the microscopic origins of non-Newtonian flow behavior in complex fluids.

8:36AM P51.00004 Shear induced diffusion in hard sphere glasses, NICK KOUMAKIS, GEORGE PETEKIDIS, FORTH & Univ. of Crete, Greece, JOHN BRADY, Chemical Engineering, Caltech, USA, FORTH TEAM, CALTECH TEAM — The response of dense hard sphere suspensions is examined during the application of steady and non-linear oscillatory shear using Brownian Dynamics (BD) simulations and experimental Light Scattering echo coupled with rheology. At rest, volume fractions around the glass transition exhibit long or infinite relaxation times. However, non-linear shear induces out of cage motions of comparable time scale to the applied rates. We found two distinct regimes in terms of stresses and dynamic response under shear. One regime for lower rates or frequencies of oscillation, governed by Brownian activated diffusion, and a second for higher rates related to shear activated diffusion. A linear dependence with rate was found for the diffusivity in the high rate regime, mirroring the viscous loss due to shear activated particle rearrangements, while diffusivities in the Brownian activated regime showed a power law exponent of less than unity. The exponent was found to increase with volume fraction. For applied rates inducing diffusivities above the in-cage diffusivity at rest, we find a time window of super-diffusive behavior, between the short time (in-cage) and long time (out-of cage) diffusivities under shear, a signature of a dynamic breaking and reforming of the cage.

8:48AM P51.00005 Diffusion in sheared athermal soft-particle suspensions: the role of inertia and dissipation mechanism, CRAIG MALONEY, KAMRAN KARIMI, Carnegie Mellon — We perform numerical simulations to study diffusion in a model bi-disperse frictionless athermal soft-particle suspension of disks in two dimensions (2D). To model athermal shear, we damp the motion of a particle *either* with respect to the globally imposed flow *or* with respect to its near neighbors. We study shear flows at various rate $\dot{\gamma}$, system size L , and damping strength b at packing fractions well above the random close packing point. At low $\dot{\gamma}$, we find a quasi-static effective transverse diffusion co-efficient, D_{eff} , which has very weak dependence on ϕ , b , or the damping mechanism yet has a pronounced linear dependence on L in agreement with what is observed in conventional models of bulk metallic glasses. Away from the quasi-static regime, D_{eff} no longer depends on L , and b has a profound impact on the scaling behavior of D_{eff} with $\dot{\gamma}$.

9:00AM P51.00006 Shear thinning in soft particle suspensions, PANAYIOTIS VOUDOURIS, Eindhoven University of Technology (a) Department of Mechanical Engineering, Materials Technology (b) Institute for Complex Molecular Systems, BERCO VAN DER ZANDEN, Eindhoven University of Technology - Department of Mechanical Engineering, DANIEL FLOREA, ZAHRA FAHIMI, HANS WYSS, Eindhoven University of Technology (a) Department of Mechanical Engineering, Materials Technology (b) Institute for Complex Molecular Systems — Suspensions of soft deformable particles are encountered in a wide range of food and biological materials. Examples are biological cells, micelles, vesicles or microgel particles. While the behavior of suspensions of hard spheres - the classical model system of colloid science - is reasonably well understood, a full understanding of these soft particle suspensions remains elusive. The relation between single particle properties and macroscopic mechanical behavior still remains poorly understood in these materials. Here we examine the surprising shear thinning behavior that is observed in soft particle suspensions as a function of particle softness. We use poly-N-isopropylacrylamide (p-NIPAM) microgel particles as a model system to study this effect in detail. These soft spheres show significant shear thinning even at very large Peclet numbers, where this would not be observed for hard particles. The degree of shear thinning is directly related to the single particle elastic properties, which we characterize by the recently developed Capillary Micromechanics technique. We present a simple model that qualitatively accounts for the observed behavior.

9:12AM P51.00007 Anisotropic Diffusion of Colloidal Particles in a Shear Flow, BRIAN LEAHY, DESMOND ONG, XIANG CHENG, ITAI COHEN, Cornell University — Asymmetrically-shaped particles show anisotropic diffusive behavior along different particle axes. This anisotropic diffusion, however, is averaged out on long time scales due to the rotational diffusion of the particles. Here we report on an experimental study of anisotropic colloidal dimers suspended in an oscillatory shear flow. A preferred orientation of the dimers arises due to the applied oscillatory shear. This results in anisotropic particle diffusion that is persistent at long time scales. We compare our results to a simple model of diffusing particles in a shear flow, and comment briefly on the possibility of using this result for assembling out-of-equilibrium colloidal structures.

9:24AM P51.00008 Pattern formation in colloidal explosions: Theory and experiment, ARTHUR STRAUBE¹, Humboldt University of Berlin, Germany, ARD LOUIS COLLABORATION², JÖRG BAUMGARTL, CLEMENS BECHINGER COLLABORATION³, ROEL DULLENS COLLABORATION⁴ — We study the nonequilibrium pattern formation that emerges when magnetically repelling colloids, trapped by optical tweezers, are abruptly released, forming colloidal explosions [EPL 94, 48008 (2011)]. For multiple colloids in a single trap, we observe a pattern of expanding concentric rings. For colloids individually trapped in a line, we observe explosions with a zigzag pattern that persists even when magnetic interactions are much weaker than those that break the linear symmetry in equilibrium. Theory and computer simulations quantitatively describe these phenomena both in and out of equilibrium. An analysis of the mode spectrum allows us to accurately quantify the nonharmonic nature of the optical traps. Colloidal explosions provide a new way to generate well-characterized nonequilibrium behavior in colloidal systems.

9:36AM P51.00009 Universal Scaling Law of Diffusion and Hydrodynamic Corrections in Colloidal Monolayers¹, XIAO-GUANG MA, Hong Kong University of Science and Technology, WEI CHEN, Fudan University, Shanghai, China, ZIREN WANG, YUAN PENG, YILONG HAN, PENG TONG, Hong Kong University of Science and Technology — Using dense monolayers of colloidal particles and the techniques of optical microscopy and particle tracking, we tested the universal scaling law of the diffusion constant of colloidal particles as a function of excess entropy. By varying the area fraction of the colloidal monolayer, we measured the diffusion constant and the corresponding pair correlation function of the colloidal particles, from which the excess entropy can be calculated. It is found that the universal scaling law applies to a monolayer of latex suspensions at an air-water interface when the inter-particle repulsions are dominant over the hydrodynamic interactions. For colloidal monolayers of hard spheres at the air-water interface and near a solid wall, the universal scaling law starts to deviate from its original form as the short-ranged hydrodynamic interactions increase.

9:48AM P51.00010 Long Range Hydrodynamic Correlations in Quasi-One-Dimensional Circular and Linear Geometries, EKATERINA KOSHELEVA, Harvard Univ., BRIAN LEAHY, Cornell Univ., HAIM DIAMANT, Tel Aviv Univ., STUART A. RICE, BINHUA LIN, Univ. of Chicago — We report the results of studies of the collective and pair diffusion coefficients of particles in two quasi-one-dimensional geometries: straight 2 mm long channels and rings with radii between 3 and 35 μm . We investigate, for both geometries, the observed density dependence in the collective diffusion coefficient as predicted by Frydel and Diamant (Phys. Rev. Letts. 104, 248302 (2010)). The origin of this density dependence is the nonvanishing $q = 0$ component of the Green's function of the linearized one-dimensional hydrodynamic equation, which is indicative of the hydrodynamic coupling resulting from collective motion of particles in periodic or infinite quasi-one-dimensional geometries.

10:00AM P51.00011 Using artificial microswimmers for particle separation, VYACHESLAV R. MISKO, University of Antwerp, Belgium, WEN YANG, Taiyuan University of Science and Technology, P.R. China, KWINTEN NELISSEN, University of Antwerp, Belgium, MINGHUI KONG, Institute of Plasma Physics, Hefei, P.R. China, FRANCOIS M. PEETERS, University of Antwerp, Belgium — Microscopic self-propelled swimmers capable of autonomous navigation through complex environments provide appealing opportunities for localization, pick-up and delivery of micro- and nanoscopic objects. Inspired by motile cells and bacteria, man-made microswimmers have been created, and their motion was studied experimentally in patterned surroundings [1]. We propose to use artificial microswimmers – Janus spheres [2] illuminated by light – as “driving agents” that move through a binary mixture of colloidal particles. We demonstrated [3] that binary mixtures can be effectively separated in this way. We analyzed the main features of the particle separation and explained mechanisms of different regimes including the one with a velocity inversion. Our finding can be readily verified in experiments with colloidal binary mixtures and could be of use for various biological and medical applications.

10:12AM P51.00012 Diffusion in Dense Inhomogeneous Colloid Suspensions in Narrow Channels, BINHUA LIN, EMILY WONDER, STUART A. RICE, Univ. of Chicago — We report the results of a study of single particle diffusion in dense colloid fluids confined in a ribbon channel geometry that is intermediate between quasi-one-dimensional (q1D) and quasi-two-dimensional (q2D). In all of the systems studied the colloid density distribution transverse to the ribbon channel is stratified with peak amplitudes that depend on the colloid density. Although the virtual walls that confine a stratum are structured with a scale length of the colloid diameter, that structure does not have an apparent influence on the single particle diffusion, which shows the characteristic features of diffusion in a q1D channel with smooth walls. We find that for all channel widths and packing fractions studied the single particle transverse diffusion coefficient in a stratum is smaller than the single particle longitudinal diffusion coefficient in the same stratum, and that the single particle longitudinal diffusion coefficient varies very little from stratum to stratum, being only slightly smaller in the dense strata next to the walls than in central strata. The lack of variation of the longitudinal diffusion coefficient with apparent stratum density is explained by application of the Fischer-Methfessel approximation to the local density in an inhomogeneous liquid. The ratio of the transverse to longitudinal diffusion coefficients varies very slowly with ribbon width, implying a very slow transition from q1D to q2D behavior.

10:24AM P51.00013 Flow of concentrated emulsion in a microchannel: walls effects and roughness impact, VINCENT MANSARD, ANNIE COLIN, LOF, Universite de Bordeaux, LYDÉRIC BOCQUET, LPMC, Université Lyon 1 — Soft glassy materials have ubiquitous rheological properties. At small stress they deform elastically. For stress above a threshold they flow like liquids. At microscale, they are composed of highly disordered particles caged by the neighborhood. Flow happens by successive cage-jumps -or rearrangement. We study concentrated emulsion as a model fluid. When it flows in confined geometry, the viscosity does not correspond to the rheometer measurements but obeys to a non-local relation (Goyon-2008) due to rearrangement's correlation. As they impose viscosity's boundary conditions, walls modify the flow. We study carefully the conditions imposed by the walls and the impact of the roughness. In a microchannel, we create a Poiseuille flow. Using a fast confocal microscope we visualize the droplets and measure the velocity with high spatial resolution. At high stress, we observe one or two discontinuities of the velocity at respectively one and two droplets' diameters. They are due to stratification of the first droplets' layers. Far from them the non-local model remains valid. We create roughness by adding controlled size patterns. The roughness modifies the apparition of the stratifications and the limit conditions on the viscosity. We will compare these results with theory.

10:36AM P51.00014 Non-equilibrium dynamics in particle-interface systems, ANNA WANG, School of Engineering and Applied Sciences, Harvard University, RYAN MCGORTY¹, University of California, San Francisco, DAVID M. KAZ², University of California, Berkeley, VINOTHAN N. MANOHARAN³, School of Engineering and Applied Sciences, Harvard University — When a particle is at equilibrium at a fluid-fluid interface, its position can be calculated with Young's law (which has been used since 1805). The non-equilibrium behavior of particles at fluid-fluid interfaces, however, is only just beginning to be studied. In this talk, we will discuss the behavior of colloidal particles as they approach and meet an oil-water interface. A variety of different systems, such as approach from both the aqueous and oil phases and using aqueous phases of various salt concentrations will be compared. The motion of the polymer microspheres is captured using digital holographic microscopy in real time. As the holograms are simply two-dimensional images, the frame rate is limited only by the CMOS sensor and frame rates of up to 2000fps are used in this study. We then analyze the high frame rate data to recover the three-dimensional trajectory and fluctuations of the particles.

10:48AM P51.00015 Granular Fluid Kinetics Approach to Modeling Soft Colloid and Polymer Materials¹, DIMITER PETSEV², JHOAN TORO-MENDOZA³, University of New Mexico, FRANK VAN SWOL⁴, University of New Mexico and Sandia National Laboratories — The objective of this study is to understand the fundamental laws governing the Brownian motion of viscoelastic particles suspended in solvent at macroscopic equilibrium. Our hypothesis is that the internal degrees of freedom of the particles couple to their translational Brownian motion and affect their mean square displacement. Our system is similar to granular fluids with the important distinction that the energy absorbed by the particles during a collision is returned back thus maintaining a global thermodynamic equilibrium. We propose a new Molecular Dynamics model system that consists of tracer Brownian particles, solvent, and a virtual third component that serves as a thermal bath. The energy that is lost in an inelastic collision between Brownian and solvent particles is returned to the bath. The bath particles are undergoing elastic collisions among themselves and also with the solvent and Brownian particles. This provides a mechanism to restore and maintain an overall thermal equilibrium in the whole system. We report data on the effect of particle inelasticity on the translational diffusion.

Wednesday, February 29, 2012 8:00AM - 11:00AM –
Session P52 GSNP DFD: Focus Session: Extreme Mechanics - Structures for Form and Function 153C

8:00AM P52.00001 Soft Robots: Manipulation, Mobility, and Fast Actuation, ROBERT SHEPHERD, FILIP ILIEVSKI, WONJAE CHOI, ADAM STOKES, STEPHEN MORIN, AARON MAZZEO, REBECCA KRAMER, Harvard, CARMEL MAJIDI, Carnegie Mellon, ROB WOOD, GEORGE WHITESIDES, Harvard — Material innovation will be a key feature in the next generation of robots. A simple, pneumatically powered actuator composed of only soft-elastomers can perform the function of a complex arrangement of mechanical components and electric motors. This talk will focus on soft-lithography as a simple method to fabricate robots—composed of exclusively soft materials (elastomeric polymers). These robots have sophisticated capabilities: a gripper (with no electrical sensors) can manipulate delicate and irregularly shaped objects and a quadrupedal robot can walk to an obstacle (a gap smaller than its walking height) then shrink its body and squeeze through the gap using an undulatory gait. This talk will also introduce a new method of rapidly actuating soft robots. Using this new method, a robot can be caused to jump more than 30 times its height in under 200 milliseconds.

8:12AM P52.00002 Low-Dimensional Generalized Coordinate Models of Large-Deformation Elastic Joints¹, LAEL ODHNER, AARON DOLLAR, Department of Mechanical Engineering, Yale University — In the field of robotics, it is increasingly common to use elastic elements such as rods, beams or sheets to allow motion between the rigid links of a robot, rather than conventional sliding mechanisms such as pin joints. Although these elastic joints are simpler to manufacture, especially at meso- and micro-scales, representational simplicity is sacrificed. It is far easier to compute the Lagrangian of a robot using joint angles as generalized coordinates, rather than by considering the large-deformation continuum behavior of elastic joints. In this talk, we will discuss our work toward finding accurate, low-dimensional discretizations of elastic joint mechanics, suitable for use in generalized coordinate models of robot kinematics and dynamics. We use modally parameterized backbone curves to describe the kinematic configuration of the elastic joints, and compute the energy associated with deformation using rod and shell theory. In the plane, only three smooth deformation modes are sufficient to describe Euler-Bernoulli bending of 90 degrees to within 1 percent. Parametric models for the three-dimensional motion of sheet hinges are more complex, but can be simplified significantly using boundary conditions and constraints imposed by ruled surface assumptions.

¹This work is supported by National Science Foundation grant IIS-0952856.

8:24AM P52.00003 Liquid-Embedded Elastomer Electronics, REBECCA KRAMER, Harvard University, CARMEL MAJIDI, Carnegie Mellon University, YONG-LAE PARK, JAMIE PAIK, ROBERT WOOD, Harvard University — Hyperelastic sensors are fabricated by embedding a silicone rubber film with microchannels of conductive liquid. In the case of soft tactile sensors, pressing the surface of the elastomer will deform the cross-section of underlying channels and change their electrical resistance. Soft pressure sensors may be employed in a variety of applications. For example, a network of pressure sensors can serve as artificial skin by yielding detailed information about contact pressures. This concept was demonstrated in a hyperelastic keypad, where perpendicular conductive channels form a quasi-planar network within an elastomeric matrix that registers the location, intensity and duration of applied pressure. In a second demonstration, soft curvature sensors were used for joint angle proprioception. Because the sensors are soft and stretchable, they conform to the host without interfering with the natural mechanics of motion. This marked the first use of liquid-embedded elastomer electronics to monitor human or robotic motion. Finally, liquid-embedded elastomers may be implemented as conductors in applications that call for flexible or stretchable circuitry, such as robotic origami.

8:36AM P52.00004 Extreme Mechanics in Soft Pneumatic Robots and Soft Microfluidic Electronics and Sensors, CARMEL MAJIDI, Carnegie Mellon University — In the near future, machines and robots will be completely soft, stretchable, impact resistance, and capable of adapting their shape and functionality to changes in mission and environment. Similar to biological tissue and soft-body organisms, these next-generation technologies will contain no rigid parts and instead be composed entirely of soft elastomers, gels, fluids, and other non-rigid matter. Using a combination of rapid prototyping tools, microfabrication methods, and emerging techniques in so-called “soft lithography,” scientists and engineers are currently introducing exciting new families of soft pneumatic robots, soft microfluidic sensors, and hyperelastic electronics that can be stretched to as much as 10x their natural length. Progress has been guided by an interdisciplinary collection of insights from chemistry, life sciences, robotics, microelectronics, and solid mechanics. In virtually every technology and application domain, mechanics and elasticity have a central role in governing functionality and design. Moreover, in contrast to conventional machines and electronics, soft pneumatic systems and microfluidics typically operate in the finite deformation regime, with materials stretching to several times their natural length. In this talk, I will review emerging paradigms in soft pneumatic robotics and soft microfluidic electronics and highlight modeling and design challenges that arise from the extreme mechanics of inflation, locomotion, sensor operation, and human interaction. I will also discuss perceived challenges and opportunities in a broad range of potential application, from medicine to wearable computing.

9:12AM P52.00005 Macrocomposite mechanical design, modeling, and behavior of physical models of bioinspired fish armor , ASHLEY BROWNING, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, CHRISTINE ORTIZ, Department of Materials Science and Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, MARY C. BOYCE, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 — The macrocomposite design of flexible biological exoskeletons, consisting of overlapping mineralized armor units embedded in a compliant tissue, is a key determinant of their mechanical function (e.g penetration resistance and biomechanical flexibility). Here, we investigate the role of macrocomposite structure, composition, geometric orientation, and spatial distribution in a flexible model natural armor system present in the majority of teleost fish species. Physical multi-material composite models are fabricated using a combination of 3-D printing and molding methods. Mechanical experiments using digital image correlation enable measurement of both the macroscopic response and underlying deformation mechanisms during various loading scenarios. Finite element-based mechanical models yield detailed insights into the roles and the tradeoffs of the composite structure providing constraint, shear, and bending mechanisms to impart protection and flexibility.

9:24AM P52.00006 Periodic Structural Solids: Mechanics and Multifunctional Applications , LIFENG WANG, Clarkson University — Triply periodic minimal surfaces have been of great interest to mathematicians, physical scientists, material scientists, and biologists. Close physical approximations to triply periodic minimal surfaces arise in a few material systems, such as block copolymers, nanocomposites, and biological exoskeletons. Here, we demonstrate the potential to design and fabricate two-component periodically ordered structures which correspond to the level set structures associated with triply periodic minimal surfaces. These structures are shown to have a unique combination of stiffness, strength, and energy absorption, as well as damage tolerance. The results provide guidelines for engineering and tailoring the nonlinear mechanical behavior and energy absorption of cocontinuous composites for a wide range of applications and further creating multifunctional materials. For example, polymeric materials which can change shape and material properties in response to external stimuli (temperature or electric field) can provide additional functionality when used as one of the phases, such as 3D shape memory. The periodic and multiphase nature of the structures also enables mechanically tunable band gap (phononic or photonic) materials, and tunable sensors in tissue engineering.

9:36AM P52.00007 Honeycombs with hierarchical organization¹ , AMIN AJDARI, BABAK HAGHPANAH JAHROMI, JIM PAPADOPOULOS, ASHKAN VAZIRI, Northeastern University — We investigated the mechanical behavior of two-dimensional hierarchical honeycomb structures using analytical, numerical and experimental methods. Hierarchical honeycombs were constructed by replacing every three-edge vertex of a regular hexagonal lattice with a smaller hexagon. Repeating this process builds a fractal-appearing structure. The resulting isotropic in-plane elastic properties (effective elastic modulus and Poisson's ratio) of this structure are controlled by the dimension ratios for different hierarchical orders. Hierarchical honeycombs of first and second order can be up to 2.0 and 3.5 times stiffer than regular honeycomb at the same mass (i.e., same overall average density). The Poisson's ratio varies from nearly 1.0 (when planar "bulk" modulus is considerably greater than Young's modulus, so the structure acts "incompressible" for most loadings) to 0.28, depending on the dimension ratios. The work provides insight into the role of structural organization in regulating the mechanical behavior of materials, and new opportunities for developing low-weight cellular structures with tailorable properties.

¹This work was supported in part by the U.S. Air Force Office of Scientific Research under AFOSR YIP grant award, #FA 9550-10-1-0145 and in part by the U.S. Department of Homeland Security under Award Number 2008-ST-061-ED0001.

9:48AM P52.00008 Buckling-induced Tunable Chirality in Rationally-Designed Surface-Attached Cellular Structures¹ , SICONG SHAN, SUNG HOON KANG, WIM NOORDUIN, School of Engineering and Applied Sciences, Harvard University, MUGHEES KHAN, Wyss Institute for Biologically Inspired Engineering, KATIA BERTOLDI, JOANNA AIZENBERG, School of Engineering and Applied Sciences, Harvard University — Chirality is crucial in understanding and controlling the behavior of living and non-living systems since the presence or absence of chirality in the structures plays important roles in their interactions with molecules, enzymes, light, and mechanical stress. Processes that induce chirality have been extensively studied at the molecular and macroscopic scales, but are relatively unexplored at the mesoscale. By rational design based on modeling, we experimentally demonstrate the controlled reversible switching between achiral and chiral configurations using swelling/de-swelling of surface-attached cellular structures. Importantly, the buckling patterns and the associated symmetry reduction of the initially achiral centrosymmetric structures could be tuned, simply by changing their dimensions. This approach opens the way to deterministically select to select the appearance of either mixed (racemic) or chiral phases. In the case of chiral transformations, spontaneous symmetry breaking resulted in the formation of large uniform areas of structures of single handedness. The fundamental understanding of this process provides a general route to designing deterministically deformable structures with dynamically switchable mechanical and/or optical properties.

¹Materials Research Science and Engineering Center under NSF Award No. DMR-0820484

10:00AM P52.00009 Buckling-induced Planar Chirality of Porous Elastic Structure , JONGMIN SHIM, SICONG SHAN, SUNG H. KANG, PAI WANG, Harvard University, BETH R. CHEN, University of Michigan, Ann Arbor, JOANNA AIZENBERG, KATIA BERTOLDI, Harvard University — We present two periodic elastomeric structures which develop planar chirality induced by buckling under uniaxial/biaxial loading. The geometry of the structure comprises a 2-D plate patterned with a regular array of circular voids. Two specific circular void arrangements are obtained by investigating buckling-induced pattern transformations for void closure. Beyond the critical load, the thin ligaments between two adjacent voids buckle leading to a cooperative buckling cascade within the 2-D plate. Both micro-scale swelling experiments and finite element simulations are used to explore the underlying mechanics in detail and to show a proof of concept of the proposed structures. During swelling, the initial non-chiral pattern of the circular voids is transformed to a deformed pattern which exhibits planar chirality through buckling-induced symmetry breaking. In order to explore the effect of planar chirality, we perform an acoustic band structure calculation at different level of deformation. The planar chirality is found to strongly affect the in-plane phononic band gaps, providing opportunities for tunable phononic band structures.

10:12AM P52.00010 Anisotropy-induced wave steering in periodic linear and nonlinear lattices , FILIPPO CASADEI, JULIAN RIMOLI, MASSIMO RUZZENE, Georgia Institute of Technology — Structural lattice configurations can be designed with tailored topologies which provide them with unusual behaviors, such as negative bulk modulus, negative Poisson's ratios, or extreme anisotropy¹. The latter is of particular relevance to explore the inherent anisotropic behavior of periodic lattices as a design paradigm for wave guiding and steering applications. The equivalent material anisotropy of square and skew periodic lattices is investigated through the application of Bloch's theorem² to the finite element discretization of the representative unit cell. The in-plane directions of wave propagation are determined through detailed analysis of the longitudinal and shear wave velocities, and verified through full-field wave propagation simulations. Similar wave behaviors are investigated analytically and experimentally for multilayer composite panels with anisotropic lay-ups in order to demonstrate the feasibility of micro structural design as an effective approach for wave management.

²Bloch F., *Z. Physik* **52**, 555 (1928)

10:24AM P52.00011 2-D Phononic Crystals – Unraveling the Effect of Void Distribution in Porous Structures, PAI WANG, JONGMIN SHIM, KATIA BERTOLDI¹, Harvard University, KATIA'S GROUP TEAM² — Phononic crystals are periodic materials consisting of different constituents with the capability to control the propagation of elastic waves. In this study, the dispersion relations of two-dimensional phononic crystals with *circular voids* are investigated using Bloch-wave analysis. Porous patterns are derived from the *Laves tilings*, which are duals of the eleven *convex uniform tilings* of the *Euclidean plane*. Numerical simulations are performed on the microstructures using finite element method. Frequency band-gaps are calculated and compared among different geometric configurations, void-volume fractions, and material properties, providing valuable insight into the behavior of phononic crystals. The predictive technical procedure developed here offers opportunities for the design of mechanical wave filters that have many potential applications such as noise-cancelling devices, acoustic wave guides and vibration isolators.

10:36AM P52.00012 Guiding of High Amplitude Stress Waves Through Stress-Induced Domain Switching in Multiphase Materials, JULIAN RIMOLI, LUCA GUIDONI, BRETT REICHARD, MASSIMO RUZZENE, Georgia Institute of Technology — Periodic and graded Multiphase Materials (MMs) are of great interest to scientists and engineers because of their unique static and dynamic mechanical properties, and the design flexibility they provide. In the linear range operation, MMs can be designed to attenuate vibrations over wide frequency bands and in specified directions, as defined by topology, geometry and material of the unit cell. Similarly, unit cell design and topology can be selected to obtain a desired anisotropy in the material, which can be exploited to alter the path of propagation of elastic and high amplitude stress waves. Specifically, steering of waves in preferential directions can be achieved through the proper arrangement of periodic hard inclusions within a matrix. Such a capability is extremely important for the design of materials capable of guiding stress waves to propagate along specified paths. In the present work, we explore the use of periodic metamaterials for wave management in force protection applications. We define topologies which adapt to high amplitude mechanical inputs, and study through numerical simulations and experiments local and global instabilities which lead to adaptive mechanical behavior through topological and structural modifications.

10:48AM P52.00013 Soft Modes and Deformations of Three-Dimensional Isostatic Periodic Lattices, ANTON SOUSLOV, Georgia Institute of Technology, T.C. LUBENSKY, University of Pennsylvania — Each particle in a three-dimensional isostatic lattice is connected by springs on average to six nearest neighbors, a condition obtained by J.C. Maxwell for marginal stability. The cubic and pyrochlore lattices satisfy this condition. By calculating the dispersion relations and the density of states for phonons in these lattices, we expand on previous studies of isostatic periodic structures [1], which have largely been focused on the simpler two-dimensional cases. The low energy phonon spectrum of these lattices exhibits features common to isostatic systems in any dimension, such as the presence of floppy modes and the scaling of a divergent length and a vanishing critical frequency. However, the allowed symmetries of an elasticity theory and the number of floppy modes depend on dimension and play a crucial role in the structure of the low-frequency response. We relate these findings to the isostatic transition in systems of close-packed athermal spheres and look at an analogy with three-dimensional crystals with zeolite structure.

Wednesday, February 29, 2012 8:00AM - 11:00AM – Session P53 GSNP: Disordered Systems: Packing 153B

8:00AM P53.00001 Analytical Construction of A Dense Packing of Truncated Tetrahedra and Its Melting Properties, YANG JIAO, SALVATORE TORQUATO, Princeton University — Dense polyhedron packings are useful models of a variety of condensed matter and biological systems and have intrigued scientists and mathematicians for centuries. Here, we analytically construct the densest known packing of truncated tetrahedra with a remarkably high packing fraction $207/208=0.995\ 192$, which is amazingly close to unity and strongly implies its optimality. This construction is based on a generalized organizing principle for polyhedra that lack central symmetry that we introduce here. The packing characteristics and equilibrium melting properties of the putative optimal packing as the system undergoes decompression are discussed.

8:12AM P53.00002 Packing fraction of dimers and anisotropic objects, TAISHAN ZHU, YULIANG JIN, HERNAN A MAKSE, Levich Institute and Physics Department, the City College of New York, New York, NY 10031, USA, MAXIMILIEN DANISCH, ENS, Cachan, ADRIAN BAULE, School of Mathematical Sciences Queen Mary, University of London — We present a statistical theory and computer simulations for the calculation of the average volume in jammed assemblies of dimer shaped objects and other anisotropic particles like spherocylinders. The theory predicts the volume fraction as a function of the coordination number of the particles.

8:24AM P53.00003 Statistical Mechanics of Athermal Packings: Incorporating Basin Volumes, ASHWIN S. S., Departments of Mechanical Engineering & Materials Science and Physics, Yale University, JERZY BLAWZDZIEWICZ, Mechanical Engineering, Texas Tech University, COREY S. O'HERN, Departments of Mechanical Engineering & Materials Science and Physics, Yale University, MARK D. SHATTUCK, Benjamin Levich Institute and Physics Department, The City College of the New York — We present a first principles formalism for the statistical mechanics of athermal packings subject to driving beyond the weak limit. Edwards hypothesized a statistical mechanics of flat measure associated with packings explored at fixed density. This ensemble has been found to work well in the limit of very weak (but non-zero) driving. Beyond the weak driving limit, the probability measures associated with jammed states become proportional to the volume of basins of attractions associated with the packings on the density landscape. We propose here, a statistical mechanics which takes into consideration the volume of basins of attraction under certain approximations. Further, the statistical mechanics takes into account the protocol by writing the partition function in terms of an integral over protocol dependent generalized coordinates. This will allow an extremum principle to determine states, in these out of equilibrium systems.

8:36AM P53.00004 Polydisperse sphere packing in high dimensions, a search for an upper critical dimension, PETER MORSE, Department of Physics: University of Oregon, MAXIME CLUSEL, Laboratoire Charles Coulomb UMR 5221, CNRS and Université Montpellier 2, F-34095, Montpellier, France, ERIC CORWIN, Department of Physics: University of Oregon — The recently introduced granocentric model for polydisperse sphere packings has been shown to be in good agreement with experimental and simulational data in two and three dimensions. This model relies on two effective parameters that have to be estimated from experimental/simulational results. The non-trivial values obtained allow the model to take into account the essential effects of correlations in the packing. Once these parameters are set, the model provides a full statistical description of a sphere packing for a given polydispersity. We investigate the evolution of these effective parameters with the spatial dimension to see if, in analogy with the upper critical dimension in critical phenomena, there exists a dimension above which correlations become irrelevant and the model parameters can be fixed *a priori* as a function of polydispersity. This would turn the model into a proper theory of polydisperse sphere packings at that upper critical dimension. We perform infinite temperature quench simulations of frictionless polydisperse sphere packings in dimensions 2-8 using a parallel algorithm implemented on a GPGPU. We analyze the resulting packings by implementing an algorithm to calculate the additively weighted Voronoi diagram in arbitrary dimension.

8:48AM P53.00005 Constraint percolation on hyperbolic lattices , JORGE LOPEZ, J.M. SCHWARZ, Physics Department, Syracuse University — Constraint percolation models include constraints on the occupation of sites to, for example, better understand the onset of glassiness in glass-forming liquids. The dynamical glass transition in the Fredrickson-Andersen model simplifies to the study of the percolation transition in k -core percolation where every occupied site must have at least k occupied neighbors. Other constraint percolation models, such as force-balance percolation, have been introduced to begin to account for mechanical equilibrium on each particle arising during the onset of jamming. To study a mean-field-like version of force-balance percolation in which the directionality of forces becomes important, we consider clusters with occupied particles satisfying the $k = 3$ -core condition and lying inside a triangle determined by three of its occupied neighbors. The model is constructed on a tessellation of the Poincaré disk, thus, bearing a hyperbolic structure. Models on such spaces exhibit mean-field-like behavior and also play an important role in generating geometric frustration in glassy systems. We analytically investigate the conditions under which there exists a transition as well as the underlying nature of the transition. We also present numerical results to compare with our analytical results.

9:00AM P53.00006 Cavity method for Edwards ensemble of jammed matter , HERNAN MAKSE, LIN BO, YULIANG JIN, the City College of New York, CHAOMING SONG, Northeastern University, SOFT MATTER AND COMPLEX SYSTEMS LAB TEAM — Two theoretical frameworks have emerged to investigate the problem of random close packings: the Edwards statistical mechanics and the cavity method for glassy systems. Here we propose a model that combines both approaches into a single Hamiltonian imposing force balance constraints and minimization of the volume of the system. The formalism can be put into the framework of constraint optimization problems as recently proposed. The cavity method then solves the problem of force balance providing a prediction of the coordination number of the jammed packing. The model can be applied to spherical frictionless and frictional particles as well as non-spherical particles providing a prediction of the coordination number as a function of the aspect ratio of the particles.

9:12AM P53.00007 Glass Transition and Random Close Packing above Three Dimensions¹ , PATRICK CHARBONNEAU, Duke University, ATSUSHI IKEDA, Universite Montpellier 2, GIORGIO PARISI, Sapienza Universita di Roma, FRANCESCO ZAMPONI, Ecole Normale Supérieure — Motivated by a recently identified severe discrepancy between a static and a dynamic theory of glasses, we numerically investigate the behavior of dense hard spheres in spatial dimensions 3 to 12. Our results are consistent with the static replica theory, but disagree with the dynamic mode-coupling theory, indicating that key ingredients of high-dimensional physics are missing from the latter. We also obtain numerical estimates of the random close packing density, which provides new insights into the mathematical problem of packing spheres in large dimension.

¹NSF Support No. DMR-1055586

9:24AM P53.00008 Packing Squares in a Torus¹ , DONALD BLAIR, CHRISTIAN SANTANGELO, JON MACHTA, University of Massachusetts Amherst — We study the densest packings of N unit squares in a torus (i.e., using periodic, square boundary conditions in 2D) using both analytical methods and simulated annealing. We find a rich array of dense packing solutions: density-one packings when N is the sum of two square integers, a family of “gapped bricklayer” Bravais lattice solutions with density $N/(N+1)$, and some surprising non-Bravais lattice configurations – including lattices of holes, as well as a configuration for $N=23$ in which not all squares share the same orientation. We assess the entropy of some of these configurations, as well as the frequency and orientation of density-one solutions as N goes to infinity.

9:36AM P53.00009 Characterization of Basin Volumes in Mechanically Stable Packings¹ , MARK D. SHATTUCK, Benjamin Levich Institute and Physics Department of The City College of New York, S.S. ASHWIN, Departments of Mechanical Engineering & Material Science and Physics, Yale University, JERZY BLAWZDZIEWICZ, Department of Mechanical Engineering, Texas Tech University, COREY S. O’HERN, Departments of Mechanical Engineering & Material Science and Physics, Yale University — There are a finite number of distinct mechanically stable (MS) packings in granular systems composed of frictionless particles. For typical packing-generation protocols employed in experimental and numerical studies, the probabilities with which the MS packings occur are highly nonuniform and depend strongly on preparation protocol. Despite intense work, it is extremely difficult to predict *a priori* the MS packing probabilities. We describe a novel computational method for calculating the MS packing probabilities by directly measuring the volume of the MS packing ‘basin of attraction’, which we define as the collection of initial points in configuration space at *zero packing fraction* that map to a given MS packing by following a particular dynamics in the density landscape. We show that there is a small core region with size l_c surrounding each MS packing in configuration space in which all initial conditions map to a given MS packing. However, we find that the MS packing probabilities are not strongly correlated with l_c and thus they are determined by complex geometric features of the landscape that are distant from the MS packing.

9:48AM P53.00010 ABSTRACT WITHDRAWN —

10:00AM P53.00011 Hierarchical freezing in a lattice model with a nonperiodic ground state¹ , JOSHUA E.S. SOCOLAR, TRAVIS BYINGTON, Duke University — A recent result in tiling theory provides a two-dimensional lattice model with nearest and next-nearest neighbor interactions that has a limit-periodic ground state. During a slow quench from the high temperature, disordered phase, the ground state emerges through an infinite sequence of phase transitions, all related by renormalizations of the temperature scale with the sequence of critical temperatures approaching zero. As the temperature is decreased, sublattices with increasingly large lattice constants become ordered. Quenching at any finite rate eventually results in glass-like state due to kinetic barriers created by simultaneous freezing on sublattices with different lattice constants.

10:12AM P53.00012 Degenerate Quasicrystal of Hard Triangular Bipyramids Stabilized by Entropic Forces , AMIR HAJI-AKBARI, MICHAEL ENGEL, SHARON GLOTZER, University of Michigan — The assembly of hard polyhedra into novel ordered structures has recently received much attention. Here we focus on triangular bipyramids (TBPs)- i.e. dimers of hard tetrahedra- which pack densely in a simple triclinic crystal with two particles per unit cell [1]. This packing is referred to as the TBP crystal. We show that hard TBPs do not form this densest packing in simulation. Instead, they assemble into a different, far more complicated structure, a dodecagonal quasicrystal, which, in the level of monomers, is identical to the quasicrystal recently discovered in the hard tetrahedron system [2], but the way that tetrahedra pair into TBPs in the nearest neighbor network is random, making it the first degenerate quasicrystal reported in the literature [3]. This notion of degeneracy is in the level of decorating individual tiles and is different from the degeneracy of a quasiperiodic random tiling arising from phason flips [4]. The $(3.4.3^2.4)$ approximant of the quasicrystal is shown to be more stable than the TBP crystal at densities below 79.7%.

10:24AM P53.00013 A Novel Decomposition of the Structure of Jammed Packings¹, MARK KANNER, MARK SHATTUCK, CUNY Graduate Center and the Benjamin Levich Institute and Physics Department of the City College of New York, CORY O'HERN, Departments of Mechanical Engineering and Physics, Yale University — We use simulations of 2D bidisperse disks to determine the properties of jammed packings and investigate the statistical mechanics of these systems. We have created a novel method for classifying structural subunits of a packing, using the structures to calculate relevant physical quantities. The classification scheme is based on a 20 type decomposition of the Delaunay triangles extracted from the centers of the particles in the packing. We find that the distribution of each type has a universal form, independent of total number of particles N in the packing for $N=8-10,000$, and that the parameters describing this form saturate as N is increased beyond $N=20$. We measure the distribution of the particle connections, the area distributions of the different structures, and nearest neighbor distributions. We explore the extent to which the nearest-neighbor distributions can predict the properties of the entire packing.

10:36AM P53.00014 8x8 and 10x10 Hyperspace Representations of SU(3) and 10-fold Point-Symmetry Group of Quasicrystals¹, ALEXANDER ANIMALU², Emeritus Professor of Physics — In order to further elucidate the unexpected 10-fold point-symmetry group structure of quasi-crystals for which the 2011 Nobel Prize in chemistry was awarded to Daniel Shechtman, we explore a correspondence principle between the number of (projective) geometric elements (points[vertices] + lines[edges] + planes[faces]) of primitive cells of periodic or quasi-periodic arrangement of hard or deformable spheres in 3-dimensional space of crystallography and elements of quantum field theory of particle physics [points (particles, lines (particles, planes (currents] and hence construct $8 \times 8 = 64 = 28 + 36 = 26 + 38$, and $10 \times 10 = 100 = 64 + 36 = 74 + 26$ hyperspace representations of the SU(3) symmetry of elementary particle physics and quasicrystals of condensed matter (solid state) physics respectively. As a result, we predict the Cabibbo-like angles in leptonic decay of hadrons in elementary-particle physics and the observed 10-fold symmetric diffraction pattern of quasi-crystals.

10:48AM P53.00015 Competition of Bergman-type approximants with other packing motifs in the Cu-Zr system, FENG ZHANG, MIN JIN, X.W. WANG, CAI-ZHUANG WANG, M.J. KRAMER, M.I. MENDELEV, KAI-MING HO, Ames Laboratory, US DOE, and Iowa State University — Knowledge about the topological and chemical ordering in metallic liquids and glasses is essential in predicting phase selection and understanding glass formation dynamics. Taking the Cu-Zr system as an example, previous studies have established Bergman-type medium-range ordering (MRO) from a structural analysis with cluster alignment methods [1]. In this study, we examine the thermodynamic stability of a crystalline approximant of Bergman-type quasicrystals [2] against packing geometries existing in other intermetallic compounds for a wide range of Cu compositions. The most stable structures for each structural motif at each Cu composition are obtained using an efficient genetic-algorithm search. Our results show that the Bergman-type approximant structure is thermodynamically favored over other packing geometries at the glass-forming region with Cu compositions around 65%, reaffirming the Bergman-type MRO is the lowest energy in Cu-Zr glasses.

8:00AM P54.00001 Magnetic field scaling of the specific heat of $\text{La}_{1.92}\text{Sr}_{0.08}\text{CuO}_4$ up to 30 Teslas¹, JONATHON KEMPER, NHMFL-Florida State University — The catalogue of experimental data on cuprate superconductivity has thoroughly characterized multiple different energy scales. Despite this, the complicated relationships between these energy scales remain poorly understood. New specific heat data on the underdoped cuprate $\text{La}_{1.92}\text{Sr}_{0.08}\text{CuO}_4$, performed in magnetic fields up to 30 Teslas demonstrates how the specific heat scaling behavior evolves as the cyclotron energy approaches the thermal energy at the superconducting transition temperature, T_c , and the mean-field calculated upper critical field, known as H_{c2} . This scaling behavior gives new insight into the complicated relationship of the various energy scales of the cuprate superconductor in the vortex state.

8:12AM P54.00002 High Magnetic Field Specific Heat in Cuprate Superconductors, SCOTT RIGGS, Stanford University, OSKAR VAFEK, JON BETTS, FEDOR BALAKIREV, ALBERT MIGLIORI, National High Magnetic Field Lab, DOUG BONN, WALTER HARDY, RUIXING LIANG, UBC, GREG BOEBINGER, National High Magnetic Field Lab — We present new high magnetic field specific heat results for both underdoped YBCO 6.51 and overdoped LSCO. With these measurements we show that across different families of cuprates and across the superconducting-doping phase diagram, 45T does very little to suppress the d-wave superconducting gap. We discuss possible interpretations of the specific heat data through the use of bandstructure, previous high field magnetization measurements, and proposed Fermi surface reconstruction scenarios.

8:24AM P54.00003 Evolution of the phase diagrams in the pseudoternary system $\text{Pr}_{1-x}\text{Nd}_x\text{Os}_4\text{Sb}_{12}$ ¹, P.-C. HO, Physics/California State University, Fresno, R.B. BAUMBACH, L. SHU, M.B. MAPLE, Physics/University of California, San Diego, S. ZHAO, D.E. MACLAUGHLIN, Physics/University of California, Riverside, T. YANAGISAWA, Hokkaido University, Japan — The pseudo ternary system $\text{Pr}_{1-x}\text{Nd}_x\text{Os}_4\text{Sb}_{12}$ has been used as a model system to investigate the effect of ferromagnetism (FM) on the unconventional superconductivity (SC), the high field ordered phase (HFOP), and quantum critical behavior [1], that was observed in $\text{PrOs}_4\text{Sb}_{12}$. SC in this system disappears near the Nd concentration $x \sim 0.58$. Between $x \sim 0.33$ and ~ 0.58 , weak FM, confirmed by the μSR experiments [2], was found to coexist with SC. In order to further inspect the possible quantum critical behavior, a power-law analysis of the temperature dependence of the electrical resistivity data was performed. Upon suppression of SC, for samples in the range $0.33 < x < 0.58$, the power-law exponent decreases from ~ 1.8 toward 1 in the temperature region below 2.5 K, resembling non-Fermi liquid behavior. Detailed T-x, H-x, and H-T phase diagrams for various x will be discussed.

8:36AM P54.00004 Resonant Ultrasound study of underdoped single crystal YBCO cuprates, ARKADY SHEKHTER, VICTOR FANELLI, NHMFL, Pulsed Field Facility, LANL, Los Alamos, NM, SCOTT RIGGS, Stanford University, Stanford, CA, YOKO SUZUKI, JON B. BETTS, ALBERT MIGLIORI, NHMFL, Pulsed Field Facility, LANL, Los Alamos, NM, GREG BOEBINGER, NHMFL, FSU, Tallahassee, FL, BRAD RAMSHAW, RUIXING LIANG, WALTER HARDY, DOUG BONN, UBC, Vancouver, Canada — We measure elastic constants and ultrasound attenuation in ultra-high quality underdoped YBCO cuprate single crystal samples. We observe a phase transition at the pseudogap temperature and reveal additional phase structure inside the pseudogap phase.

8:48AM P54.00005 A Pre-Formed Pair Approach to the Dynamical (THz) Complex Conductivity in the Cuprates, DAN WULIN, VIVEK MISHRA, KATHRYN LEVIN, University of Chicago — In this talk we present a theory for $\sigma(\omega) = \sigma_1(\omega) + i\sigma_2(\omega)$ in the underdoped cuprates. Our work presumes that the pseudogap is associated with preformed pairs. We demonstrate how the puzzling extended range of finite $\sigma_2(\omega)$ above T_c (implying a “dynamical superfluid density”) arises from a new form of pair breaking contribution to $\sigma_2(\omega)$. This is only present in these moderately clean superconductors because of stronger than BCS attraction (BCS-BEC). Sum rule compatibility and good semiquantitative agreement with experiment is found.

9:00AM P54.00006 Origin of multiple quantum oscillation frequencies from single carrier nodal pocket in the underdoped cuprate superconductor YBCO, SUCHITRA E. SEBASTIAN, G.G. LONZARICH, University of Cambridge, N. HARRISON, M.M. ALTARAWNEH, NHMFL, Los Alamos, R. LIANG, D.A. BONN, W.N. HARDY, University of British Columbia — Quantum oscillations are measured in the underdoped high T_c cuprate superconductor $\text{YBa}_2\text{Cu}_3\text{O}_{6+x}$, revealing multiple frequencies. An extended study over a broad angular range and magnetic field range up to 95 T accompanied by detailed harmonic analysis is presented, establishing the multiple frequencies to arise from Fermi surface reconstruction yielding a single carrier nodal pocket. Scenarios are presented for the origin of multiple frequencies from this nodal pocket.

9:12AM P54.00007 ABSTRACT MOVED TO L21.00008 —

9:24AM P54.00008 Synthesis, $P - T$ phase diagram, and T_c of $R_2\text{Ba}_4\text{Cu}_7\text{O}_{15}$ ($R = \text{Dy}, \text{Y}, \text{DyY}, \text{GdY}$)¹, SEYED AHMAD SABOK-SAYR, BOGDAN DABROWSKI, STANISLAW KOLESNIK, Department of Physics, Northern Illinois University — The oxygen pressure - temperature phase diagrams of $R_2\text{Ba}_4\text{Cu}_{15}$ ($R = \text{Dy}, \text{Y}, \text{Er}, \text{DyY}, \text{GdY}, \text{and EuY}$) superconductors have been investigated in the temperature range between 850 and 1025°C and the pressure range between 1 and 50 atm. O_2 . The relative fraction of the phases: 123, 124, and 247, was determined by studying the intensity of the x-ray diffraction peaks of each phase. The condition at which the phase pure 247 exists was determined to be $P = 10 \text{ atm}$ and $T = 1025^\circ\text{C}$. Under these conditions samples with larger size $R = \text{LaY}, \text{NdY}, \text{SmY}, \text{and Eu}$ fail to form pure 247 phase. Annealing at $P = 200 \text{ atm. O}_2$ and 400°C was used to increase oxygen content of the as-synthesized materials and to induce superconductivity. The highest transition temperatures of 70K were observed for $R = \text{Y}$ compositions.

9:36AM P54.00009 Pseudogap temperature along the Widom line of a first-order transition in doped Mott insulators, GIOVANNI SORDI, Institut Laue-Langevin, Grenoble, France, PATRICK SEMON, Universite de Sherbrooke, K. HAULE, Rutgers University, A.-M. S. TREMBLAY, Universite de Sherbrooke and Canadian Institute for Advanced Research — A state of matter with unusual physical properties, dubbed “the pseudogap”, appears below a characteristic temperature T^* in hole-doped high-temperature superconductors. In many cases, it is not even clear whether T^* is a crossover or a phase transition. We construct the normal-state phase diagram of the two dimensional Hubbard model using cellular dynamical mean-field theory. We find that T^* is a crossover line above the critical endpoint of a first-order phase transition between two metallic phases, one with a pseudogap and one without. Thus T^* appears in a new light: it is an unexpected example of a phenomenon observed in fluids, namely a sharp crossover between different dynamical regimes along a line of thermodynamic anomalies that appears above a first-order phase transition, the Widom line. Our findings thus suggest that the critical point of a first-order transition, and not a quantum critical point, can be the organizing principle for the rich behavior of the normal state of the cuprates. 11:15AM Q2.00001 Magnons, Spin Current and Spin Seebeck Effect, SADAMICHI MAEKAWA, Japan Atomic Energy Agency — When metals and semiconductors are placed in a temperature gradient, the electric voltage is generated. This mechanism to convert heat into electricity, the so-called Seebeck effect, has attracted much attention recently as the mechanism for utilizing wasted heat energy. [1]. Ferromagnetic insulators are good conductors of spin current, i.e., the flow of electron spins [2]. When they are placed in a temperature gradient, generated are magnons, spin current and the spin voltage [3], i.e., spin accumulation. Once the spin voltage is converted into the electric voltage by inverse spin Hall effect in attached metal films such as Pt, the electric voltage is obtained from heat energy [4-5]. This is called the spin Seebeck effect. Here, we present the linear-response theory of spin Seebeck effect based on the fluctuation-dissipation theorem [6-8] and discuss a variety of the devices.

11:51AM Q2.00002 Spin Wave Transport in Microscopic Magnetic Structures¹, HELMUT SCHULTHEISS, Materials Science Division, Argonne National Laboratory, and Department of Physics and Research Center OPTIMAS, University of Kaiserslautern — The coherent transport of spin information is one of the great challenges in condensed matter physics and is of fundamental importance for the development of spintronic devices. Spin waves carry angular momentum and can be utilized to transport spin information over distances much larger than the spin diffusion length in metals. Recent experiments showing that spin waves can be manipulated via spin currents and vice versa due to spin torque, spin pumping, spin Hall and spin Seebeck effects have drawn great attention to the transport properties of spin waves. Fundamental topics are spin-wave propagation characteristics in microstructures with reduced dimensionality^{2,3}, realization of spin-wave transport in two-dimensional waveguides, including directional changes along the spin-wave propagation path⁴, and the effect of nonlinear damping mechanisms when spin waves are spatially confined in microstructures. We use phase- and time-resolved Brillouin light scattering microscopy to address these topics in micron-sized spin-wave conduits made from permalloy. These experiments allow us to develop a simple model for calculating dispersion relations in spin-wave conduits. This model can be applied to understand how spin waves are transported in conduits with broken translation symmetry and how nonlinear damping via four-magnon-scattering is enhanced due to spatial confinement.

12:27PM Q2.00003 Using magnons to probe spintronic materials properties¹, ROBERT MCMICHAEL, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD — For many spin-based electronic devices, from the read sensors in modern hard disk drives to future spintronic logic concepts, the device physics originates in spin polarized currents in ferromagnetic metals. In this talk, I will describe a novel “Spin Wave Doppler” method that uses the interaction of spin waves with spin-polarized currents to determine the spin drift velocity and the spin current polarization [1]. Owing to differences between the band structures of majority-spin and minority-spin electrons, the electrical current also carries an angular momentum current and magnetic moment current. Passing these coupled currents through a magnetic wire changes the linear excitations of the magnetization, i.e. spin waves. Interestingly, the excitations can be described as drifting “downstream” with the electron flow. We measure this drift velocity by monitoring the spin-wave-mediated transmission between pairs of periodically patterned antennas on magnetic wires as a function of current density in the wire. The transmission frequency resonance shifts by $2\pi\Delta f = \mathbf{v} \cdot \mathbf{k}$ where the drift velocity v is proportional to both the current density and the current polarization P . I will discuss measurements of the spin polarization of the current in $\text{Ni}_{80}\text{Fe}_{20}$ [2], and novel alloys $(\text{CoFe})_{1-x}\text{Ga}_x$ [3] and $(\text{Ni}_{80}\text{Fe}_{20})_{1-x}\text{Gd}_x$ [4].

1:03PM Q2.00004 Interaction between spin-wave excitations and pure spin currents in magnetic structures¹, ANTONIO AZEVEDO, Departamento de Física, Universidade Federal de Pernambuco, 50670-901, Recife, PE, Brazil — The generation of pure spin current (PSC) in magnetic structures has attracted much attention not only for its fundamental importance in spintronics, but also because it opens up potential applications. One of the most exciting aspects of this area is the interplay between spin-waves (SW) and PSC. Here we report experimental results in which the PSC, generated by both spin pumping (SPE) [1] and spin Seebeck (SSE) [2] effects, can exert a spin-transfer torque sufficient to compensate the SW relaxation in yttrium iron garnet (YIG)/non-magnetic structures. By measuring the propagation of SW packets in single-crystal YIG films we were able to observe the amplification of volume and magnetostatic modes (MSW) by both SSE and SHE [3,4]. The excitation and detection of the SW packets is carried out by using a MSW delay line device. In both cases the amplification is attributed to the spin-transfer torque due to PSC generated by SSE as well as SHE. It will also be presented new results in which PSC are simultaneously excited by SSE and SPE effects in YIG films. While the spin current generated by SPE is obtained by exciting the ferromagnetic resonance (FMR) of the YIG film, the spin current due to SSE is created by applying a temperature gradient along the film plane. The effect of the superposition of both spin currents is characterized by measuring the spin Hall voltage (V_H) along thin strips of Pt deposited on top of the YIG films. Whereas V_H corresponding to the uniform FMR is amplified due to the SSE the voltages corresponding to the other magnetostatic spin-wave modes are attenuated [5].

1:39PM Q2.00005 Manipulation of Spin Waves in Yttrium Iron Garnet Thin Films through Interfacial Spin Scattering, MINGZHONG WU, Department of Physics, Colorado State University — Spin waves in magnetic films have many properties that can be utilized for microwave signal processing and logic operations. These applications, however, are bottlenecked by the damping of spin waves. This presentation reports on a new method for the amplification of spin waves. Specifically, the presentation reports the electric manipulation of spin waves in yttrium iron garnet (YIG) thin films via interfacial spin scattering (ISS). Experiments used a 4.6 μm -thick YIG film strip with a 20 nm-thick Pt capping layer. A dc pulse was applied to the Pt film that produced a spin current along the Pt thickness direction via the spin-Hall effect. As the spin current scatters off the surface of the YIG film, it exerts a torque on the YIG surface spins. Due to the dipolar and exchange interactions, the effect of this torque is extended to other spins across the YIG thickness and thereby to spin-wave pulses traveling in the YIG film. The net effect of the ISS process depends critically on the relative orientation of (1) the magnetic moments of the electrons in the Pt layer that scatter off the YIG surface and (2) the precession axis of the magnetic moments on the YIG surface. When they are anti-parallel, the spin-wave damping is reduced and the amplitude of a traveling spin-wave pulse is increased. In a parallel configuration, the pulse experiences an enhanced attenuation.

Wednesday, February 29, 2012 11:15AM - 2:15PM –

Session Q3 DCMP: Invited Session: Recent Advances in Pnictide Superconductors 205AB

11:15AM Q3.00001 Study of the Multiorbital Hubbard Model for the Fe-Superconductors Beyond Weak Coupling , ELBIO DAGOTTO, Department of Physics, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory — A variety of experimental and theoretical investigations indicate that the pnictides and chalcogenides are materials with on-site Hubbard repulsion intermediate between weak coupling, where simple nesting ideas apply, and strong coupling where the spins are localized. For this reason, it is desirable to broaden the range of couplings theoretically studied as well as the many-body models and techniques employed. In this talk, an extensive analysis of model Hamiltonians for the Fe-based superconductors is presented. The multiorbital Hubbard models with two, three, and five orbitals are studied, via the Hartree-Fock approximation and exact diagonalization techniques. The main topics to be discussed are: magnetic ordering tendencies [1], range of realistic Hubbard repulsion and Hund couplings [2], orbital-weight redistribution at the Fermi surface and comparison with photoemission data [3], low-temperature transport properties [4], and competing pairing channels [5]. The possible magnetic states of the $\sqrt{5} \times \sqrt{5}$ Fe-vacancy arrangement will also be presented [6]. The experimental reports of local moments at room temperature leads to our most recent efforts employing a three-orbital spin-fermion model, analyzed via Monte Carlo simulations, to study the temperature dependence of the (anisotropic) conductance [7]. It is concluded that considerable progress has been made in the understanding of these materials in spite of their difficult range of intermediate couplings. However, the existence of several open problems will also be discussed.

11:51AM Q3.00002 Doping - dependent anisotropy of the superconducting gap in underdoped pnictide superconductors , RUSLAN PROZOROV, The Ames Laboratory — The in-plane London penetration depth, $\Delta\lambda(T)$, was studied in single crystals of $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ ("Ba122") and $\text{Ca}_{10}(\text{Pt}_3\text{As}_8)[(\text{Fe}_{1-x}\text{Pt}_x)_2\text{As}_2]_5$ ("10-3-8"). Whereas in Ba122 magnetism and superconductivity coexist in the underdoped regime, the 10-3-8 compound exhibits a clear separation of two order parameters. By comparing the results obtained in these two systems, we could study general features of the superconducting gap structure as function of doping in the underdoped regime. Similar to all other pnictides, the low-temperature variation of London penetration depth exhibits a power-law behavior, $\Delta\lambda(T) = AT^n$, in both systems. Moving towards the underdoped edge of the superconducting dome, the exponent n decreases well below scattering - limited value of $n = 2$ and, at the same time, the pre-factor A increases. Both trends indicate an increasing anisotropy of the superconducting gap in more underdoped compounds. These and previous results suggest that the development of the superconducting gap anisotropy towards the underdoped edge of the superconducting dome is an intrinsic property of iron pnictides, similar to the known tendency on the overdoped side where magnetism and superconductivity do not interfere.

In collaboration with M.A. Tanatar, H. Kim, The Ames Laboratory; Bing Shen, Hai-Hu Wen, Nanjing University; and N. Ni, R.J. Cava, Princeton University.

12:27PM Q3.00003 Nematic susceptibility and quantum criticality in Fe-pnictide superconductors , JAMES ANALYTIS, Stanford Institute for Material and Energy Science — The concept of broken symmetry is ubiquitous in condensed matter physics because it allows us to write the proper Hamiltonian description of an electron in a solid. Determining which symmetry is broken and how it is broken is therefore crucial. I will present results from transport and magnetization experiments on both underdoped and overdoped pnictide superconductors of the "122" structural motif that help reveal the intrinsic symmetry of the electronic ground state. We reveal the nature of the nematic susceptibility as optimal doping is approached on the underdoped side, and the breakdown of Fermi liquid like quasiparticles from the overdoped side. We discuss the universality of these properties to other pnictides.

1:03PM Q3.00004 Controlling vortex pinning and vortex phase diagrams of FeAs-based superconductors through particle irradiation and substitution , ULRICH WELP, Argonne National Laboratory — The prominent vortex pinning features of the Ba-122 and Sm-1111 family of pnictide superconductors are presented. For isovalently doped $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ we observe the systematic evolution of vortex pinning with increasing P-doping from fishtail behavior to a distinct peak effect near the irreversibility field to a reversible magnetization and Bean Livingston surface barriers. The enhancement of vortex pinning resulting from heavy ion and proton irradiation is shown to arise from delta-Tc-type pinning. These results will be compared to those on optimally doped $\text{BaKFe}_2\text{As}_2$ and $\text{SmFeAs}(\text{O}_{1-x}\text{F}_x)$. High-energy heavy-ion irradiation induced defects lead to a decrease in the superconducting anisotropy, an increase in the slope of the temperature dependence of the irreversibility line and only small suppression of Tc. In all cases, we see a large enhancement of the critical current following particle irradiation. In particular, on $\text{BaKFe}_2\text{As}_2$ irradiated to a dose matching field of 21 T with 1.3-GeV Pb-ions, $J_c \sim 4 \text{ MA/cm}^2$ at 5 K and in 7 T || c is achieved, comparable to results for YBCO coated conductors at the same temperature and field.

1:39PM Q3.00005 Unusual electronic structure and pairing in the $K_x\text{Fe}_{2-y}\text{Se}_2$ and $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ superconductors, DONGLAI FENG, State Key Laboratory of Surface Physic and Department of Physics, Fudan University, Shanghai, China — In this talk, we present the angle resolved photoemission study of the unusual electronic structure and pairing behavior in two rather unique iron based superconductors: $K_x\text{Fe}_{2-y}\text{Se}_2$ and $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$. For $K_x\text{Fe}_{2-y}\text{Se}_2$, large electron Fermi surfaces are observed around the zone corners with an almost isotropic superconducting gap of 10.3 meV, while there is no hole Fermi surface near the zone center, which demonstrate the inter-band scattering or Fermi surface nesting is not a necessary ingredient for the unconventional superconductivity in iron-based superconductors. Moreover, two insulating and one semiconducting parental phases of $K_x\text{Fe}_{2-y}\text{Se}_2$ were identified. The two insulating phases exhibit Mott-insulator-like signatures, and one of the insulating phases is mesoscopically phase-separated from the superconducting/semiconducting phase in the superconductor/semiconductor [2]. For $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$, which is a prototypical iron-based superconductor with nodal gap behaviors, we have determined the systematic change of its low energy electronic structures as a function of the Phosphor concentration. We found the so-called iso-valent doping actually introduce significant amount of holes into the system. The chemical pressure effect is largely a doping effect in addition to the non-rigid band behavior [3]. Moreover, we report the direct observation of a circular line node on the largest hole Fermi surface around the Z point at the Brillouin zone boundary. We found that the nodes are due to the strong three dimensional character of this Fermi surface (large k_z dispersion, strong mixing of $d_{3z^2-r^2}$ orbitals), instead of d-wave pairing or other scenarios involving the electron pockets [4].

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q4 DAMOP: Focus Session: Many-body Quantum Phases in Cold Atom Systems 205C

11:15AM Q4.00001 Orbital ice: an exact Coulomb phase on the diamond optical lattice¹, GIA-WEI CHERN, University of Wisconsin at Madison and Los Alamos National Lab, CONGJUN WU, University of California, San Diego — The rapid advances in loading and controlling alkali atoms on the excited bands of optical lattices have made it possible to investigate orbital-related many-body physics in new settings. Here we demonstrate the existence of orbital Coulomb phase as the exact ground state of p -orbital exchange Hamiltonian on the diamond lattice. The Coulomb phase is an emergent state characterized by algebraic dipolar correlations and a gauge structure resulting from local constraints (ice rules) of the underlying lattice models. For most ice models on the pyrochlore lattice, these local constraints are a direct consequence of minimizing the energy of each individual tetrahedron. On the contrary, the orbital ice rules are emergent phenomena resulting from the quantum orbital dynamics. We show that the orbital ice model exhibits an emergent geometrical frustration by mapping the degenerate quantum orbital ground states to the spin-ice states obeying the 2-in-2-out constraints on the pyrochlore lattice. We also discuss possible realization of the orbital ice model in optical lattices with p -band fermionic cold atoms. [1] Gia-Wei Chern and Congjun Wu, arXiv:1104.1614 (2011).

11:27AM Q4.00002 Time reversal symmetry breaking of p -orbital bosons in a one-dimensional optical lattice¹, XIAOPENG LI, ZIXU ZHANG, W. VINCENT LIU, University of Pittsburgh — We study bosons loaded in a one-dimensional optical lattice of two-fold p -orbital degeneracy at each site. Our numerical simulations find an anti-ferro-orbital $p_x + ip_y$, a homogeneous p_x Mott insulator phase and two kinds of superfluid phases distinguished by the orbital order (anti-ferro-orbital and para-orbital). The anti-ferro-orbital order breaks time reversal symmetry. Experimentally observable evidence is predicted for the phase transition between the two different superfluid phases. We also discover that the quantum noise measurement is able to provide a concrete evidence of time reversal symmetry breaking in the first Mott phase.

11:39AM Q4.00003 Correlated phases of bosons in tilted, frustrated lattices¹, SUBIR SACHDEV, Harvard University, SUSANNE PIELAWA, WIEZMANN INSTITUTE OF SCIENCE, TAKUAYA KITAGAWA, EREZ BERG, Harvard University — We study the “tilting” of Mott insulators of bosons into metastable states. These are described by Hamiltonians acting on resonant subspaces, and have rich possibilities for correlated phases with non-trivial entanglement of pseudospin degrees of freedom measuring the boson density. We extend a previous study (Phys. Rev. B 66, 075128 (2002)) of cubic lattices to a variety of lattices and tilt directions in 2 dimensions: square, triangular, decorated square, and kagome, while noting the significance of three-body interactions. We find quantum phases with Ising density wave order, with superfluidity transverse to the tilt direction, a sliding Luttinger liquid phase, and quantum liquid states with no broken symmetry. Some cases map onto effective quantum dimer models.

11:51AM Q4.00004 Quantum simulations with ultracold atoms¹, NIKOLAY PROKOFIEV, University of Massachusetts, Amherst — Precise understanding of strongly interacting systems, from electrons in materials and frustrated magnets to nuclear matter, is a major challenge for modern physics. Often, theoretical description of key models is severely plagued by the intricate quantum mechanics at play. This prompted a challenging effort of using ultra-cold atoms to realize Feynman’s emulators of fundamental microscopic models. I will discuss some of the current efforts in realizing quantum simulators for cold bosonic and fermionic systems and how the theory tries to caught up with the experiment in making reliable predictions for strongly interacting quantum matter.

12:27PM Q4.00005 A Mott Glass to Superfluid Transition for Random Bosons in Two Dimensions, DAVID PEKKER, SHANKAR IYER, GIL REFAEL, Caltech — We study the zero temperature superfluid-insulator transition for a two-dimensional model of interacting, lattice bosons in the presence of quenched disorder and particle-hole symmetry. We follow the approach of a recent series of papers by Altman, Kafri, Polkovnikov, and Refael, in which the strong disorder renormalization group is used to study disordered bosons in one dimension. Adapting this method to two dimensions, we study several different species of disorder and uncover universal features of the superfluid-insulator transition. In particular, we locate an unstable finite disorder fixed point that governs the transition between the superfluid and a gapless, glassy insulator. We present numerical evidence that this glassy phase is the incompressible Mott glass and that the transition from this phase to the superfluid is driven by percolation-type process. Finally, we provide estimates of the critical exponents governing this transition.

12:39PM Q4.00006 Disordered Supersolids in the Extended Bose-Hubbard Model¹, VITO SCAROLA, BHARGAV KEMBURI, Virginia Tech — Studies of the extended Bose-Hubbard model seek to capture the essential properties of a wide variety of physical systems including helium, Josephson junction arrays, certain narrow-band superconductors, and bosons in optical lattices. We theoretically study the stability of lattice supersolid states in the extended Bose-Hubbard model with bounded spatial disorder. We construct a disorder mean field theory and compare with quantum Monte Carlo calculations. We find that the supersolid survives weak disorder on the simple cubic lattice. We also find that increasing disorder strength can transform a lattice solid into a supersolid as it tends to percolate through the disorder landscape.

12:51PM Q4.00007 Density instabilities in a two-dimensional dipolar Fermi gas, MEERA PARISH, University College London, FRANCESCA MARCHETTI, Universidad Autonoma de Madrid — We investigate the inhomogeneous phases of fermionic polar molecules confined in a single two-dimensional (2D) layer, where the molecule dipole moments are all aligned by an external electric field. We show that the Random Phase Approximation (RPA) for the density-density response function is never accurate for the 2D dipolar Fermi gas. To incorporate correlations beyond RPA, we use an improved version of the Singwi-Tosi-Land-Sjolander scheme, which has been successful for electron systems. In addition to density-wave instabilities, our formalism captures the collapse instability that is expected from Hartree-Fock calculations but is absent from RPA. Crucially, we find that when the dipoles are oriented perpendicular to the layer, the system spontaneously breaks rotational symmetry and forms a stripe phase, in defiance of conventional wisdom.

1:03PM Q4.00008 Scaling of noise correlations of hard-core bosons in incommensurate lattices, KAI HE, Georgetown University, INDUBALA I. SATIJA, George Mason University; Joint Quantum Institute, NIST, CHARLES W. CLARK, Joint Quantum Institute, NIST, ANA MARIA REY, JILA, NIST, MARCOS RIGOL, Georgetown University — We study the scaling of the momentum distribution function and the noise correlations in the Mott insulator, Bose glass, and superfluid quantum phases of hard-core bosons subjected to quasi-periodic disorder. The exponents of the correlation functions at the superfluid to Bose-glass transition are found to be approximately one half of the ones that characterize the superfluid phase. We also find a divergence in the derivative of the noise correlation peaks with respect to the strength of disorder at the superfluid to Bose-glass critical point. This behavior is found not to occur in the corresponding free fermion system, where an Anderson-like transition takes place at the same critical point.

1:15PM Q4.00009 Quantum Orders and Space-Time Vortices for Spin 2 Atomic Chains, ARI TURNER, University of Amsterdam, FRANK POLLMANN, Max-Planck-Institute for the Physics of Complex Systems, ASHVIN VISHWANATH, University of California, Berkeley — Laser cooled atoms with spin can become magnetically ordered, like electrons in solids, but a greater variety of orders is possible in this setting. Spin one atoms can form nematic states with the symmetry of an undirected line segment while spin two atoms can form states with the symmetry of a tetrahedron. Such atoms could be confined to a one-dimensional optical lattice. In one dimension, quantum fluctuations become much more significant, and lead to a few interesting phases. In particular, the nematic state spontaneously breaks translational symmetry. If a state has a Berry's phase of a certain order under rotations, the fluctuations will often be modulated with a period of the same order. I will argue that this connection can be broken for a non-abelian symmetry group—both uniform and periodic phases can be stabilized. As an example, computer calculations (with DMRG) on a tetrahedral state find both a uniform and a period 3 phase.

1:27PM Q4.00010 Thermal versus quantum fluctuations of optical lattice fermions, CHRIS HOOLEY, SUPA, University of St Andrews, UK, VIVALDO CAMPO, Universidade Federal de Sao Carlos, Brazil, KLAUS CAPELLE, Universidade Federal do ABC, Brazil, JORGE QUINTANILLA, SEPnet, University of Kent and STFC Rutherford Appleton Laboratory, UK, VITO SCAROLA, Virginia Tech, USA — We show that, for fermionic atoms in a one-dimensional optical lattice, the fraction of atoms in doubly occupied sites is a highly non-monotonic function of temperature. We demonstrate that this property persists even in the presence of realistic harmonic confinement, and that it leads to a suppression of entropy at intermediate temperatures that offers a clear route to adiabatic cooling. Our interpretation of the suppression is that such intermediate temperatures are simultaneously too high for quantum coherence and too low for significant thermal excitation of double occupancy thus offering a clear indicator of the onset of quantum fluctuations.

1:39PM Q4.00011 Tunable quantum glasses and phase transitions of atoms and photons: first-predictions for glassy physics with many-body cavity QED¹, PHILIPP STRACK, SUBIR SACHDEV, Harvard University — Recent studies of strongly interacting atoms and photons in opticalcavity have rekindled interest in the Dicke model of atomic qubitsto discrete photon cavity modes. In this talk, we argue thatof the Dicke model with variable atom-photon couplings canrise to a ground state phase diagram exhibiting quantum phasebetween paramagnetic, ferromagnetic, and a spin glass phase. These quantum optics realizations of quantum glasses are distinctive to condensed matter systems and provide new opportunities for glassy physics with many-bodyQED. The photon-mediated random couplings between the atomic qubitssing spins) are truly long-ranged and the theory for these systemsanalytically tractable. We compute atomic and photon spectrafunctions across this phase diagram, and outline how ourcan be observed in experiments.

1:51PM Q4.00012 ABSTRACT WITHDRAWN —

2:03PM Q4.00013 The boson-Hubbard model on a kagome lattice with a sextic ring-exchange term¹, VALERY ROUSSEAU, KA-MING TAM, JUANA MORENO, MARK JARRELL, Louisiana State University (LSU) — We present exact quantum Monte Carlo simulations of hard-core bosons in a two-dimensional Kagome lattice with a sextic ring-exchange term. We study how the superfluid density evolves as the ring-exchange interactions are increased. We show that the system becomes unstable in the limit of large interactions at all fillings and undergoes a phase separation, except at $\frac{1}{3}$ and $\frac{2}{3}$ fillings for which the superfluid density vanishes and a solid state forms.

11:15AM Q5.00001 Solution to the d=2 Hertz-Millis problem from a hairy electron star¹, KA WAI LO, University of Illinois at Urbana Champaign, MOHAMMAD EDALATI, University of Texas at Austin, PHILIP PHILLIPS, University of Illinois at Urbana Champaign — We use holography to study the spontaneous condensation of a neutral order parameter in a (2+1)-dimensional field theory at zero-temperature and finite density, dual to the electron star background of Hartnoll and Tavanfar. An appealing feature of this field theory is the emergence of an IR Lifshitz fixed-point with a finite dynamical critical exponent z , which is due to the strong interaction between critical bosonic degrees of freedom and a finite density of fermions (metallic quantum criticality). We show that under some circumstances the electron star background develops a neutral scalar hair whose holographic interpretation is that the boundary field theory undergoes a quantum phase transition, with a Berezinski-Kosterlitz-Thouless character, to a phase with a neutral order parameter. Including the backreaction of the bulk neutral scalar on the background, we argue that the two phases across the quantum critical point have different z , a novelty that exists in certain quantum phase transitions in condensed matter systems. We also analyze the system at finite temperature and find that the phase transition becomes, as expected, second-order. Embedding the neutral scalar into a higher form, a variety of interesting phases could potentially be realized for the boundary field

¹National Science Foundation Division of Material Research 0940992

11:27AM Q5.00002 Non-Relativistic Holographic Quantum Liquids¹, JUVEN WANG, ALLAN ADAMS, Massachusetts Institute of Technology — We explore the phase structure of a holographic toy model of superfluid states in non-relativistic conformal field theories. At low background mass density, we find a familiar second-order transition to a superfluid phase at finite temperature. Increasing the chemical potential for the probe charge density drives this transition strongly first order as the low-temperature superfluid phase merges with a thermodynamically disfavored high-temperature condensed phase. At high background mass density, the system reenters the normal phase as the temperature is lowered further, hinting at a zero-temperature quantum phase transition as the background density is varied. Given the unusual thermodynamics of the background black hole, however, it seems likely that the true ground state is another configuration altogether.

¹The work based on: <http://arxiv.org/abs/1103.3472> and works to appear on arXiv.org.

11:39AM Q5.00003 Striped Superconductor and Holography, GEORGE SIOPSIS, University of Tennessee at Knoxville, JIMMY HUTASOIT, West Virginia University, JASON THERRIEN, SUMAN GANGULI, University of Tennessee at Knoxville — Using gauge/gravity duality, we analytically study the properties of a strongly coupled striped superconductor, with the charge density wave sourced by a modulated chemical potential. The calculation is done in the large modulation wavenumber Q regime and comparing the results with numerical calculations, we find good agreement for $Q \geq 3T_c$. In the absence of a homogeneous term in the chemical potential, we show that the critical temperature scales as a negative power of Q for scaling dimensions $\Delta < \frac{3}{2}$, whereas for $\Delta > \frac{3}{2}$, there is no phase transition above a certain critical value of Q . The order parameter or the condensate is found to scale as a positive power of Q such that the gap is proportional to Q . We discuss how these results change if a homogeneous term is added to the chemical potential. We also calculate the conductivity with its spatial dependence.

11:51AM Q5.00004 Holographic noise near quantum critical points¹, ANDREW GREEN, London Centre of Nanotechnology, JULIAN SONNER, DAMTP, University of Cambridge — The dynamical scaling present in equilibrium correlations near to a quantum critical point suggests the possibility of universal, out-of-equilibrium steady states. This has been demonstrated in analyses of the response of the bosonic Hubbard model to a strong electric field. The universal out-of-equilibrium behaviour is particularly apparent in the current noise; at high field, a current noise power $S_j \propto \sqrt{E}$ was found which was interpreted as Johnson-like with an effective temperature $\propto \sqrt{E}$ [Phys. Rev. Lett. 97, 227003 (2006)]. We revisit this problem using the holographic mapping to a classical gravitational system. We recover a current noise that extends the previously known equilibrium and strongly out-of-equilibrium results with a full interpolation between the two: $S_j \propto T_{eff}$ with $T_{eff} = (T^4 + E^2/\pi^4)^{1/4}$.

¹We acknowledge financial support from Trinity College Cambridge, the EPSRC and KITP Santa Barbara

12:03PM Q5.00005 Out-of-equilibrium conductivity and current noise at quantum critical points, ANDREW BERRIDGE, London Centre for Nanotechnology, M.J. BHASEEN, Cavendish Laboratory, Cambridge, A.G. GREEN, London Centre for Nanotechnology — Quantum critical points display universal behaviour across a wide range of physical systems. These effects appear in both thermodynamics and transport. Such behaviour should also be present out-of-equilibrium where, for example, the current and current noise should follow scaling laws as a function of applied field. These expectations have been borne out in calculations for out-of-equilibrium transport at the Superfluid-Mott Insulator quantum critical point of the Bose-Hubbard model [?, ?]. These analyses extend the quantum Boltzmann description [?] of equilibrium transport using a trick of the $1/N$ expansion. Here we use an epsilon expansion to obtain similar results. This approach has the advantage of making the physical constraints of the results more transparent. We also present preliminary analysis of the evolution to the non-equilibrium steady state after the electric field is applied.

12:15PM Q5.00006 Wigner-Mott scaling of transport near the two-dimensional metal-insulator transition, MILOS RADONJIC, DARKO TANASKOVIC, Scientific Computing Laboratory, Institute of Physics Belgrade, University of Belgrade, Pregrevica 118, 11080 Belgrade, Serbia, VLADIMIR DOBROSavlJEVIC, Department of Physics and National High Magnetic Field Laboratory, Florida State University, Tallahassee, Florida 32306, GABRIEL KOTLIAR, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854 — Thermal destructions of heavy quasiparticles often dominates the transport behavior of many strongly correlated materials. It typically leads to pronounced resistivity maxima in the incoherent regime around the coherence temperature T^* , reflecting the tendency of carriers to undergo Mott localization following the demise of the Fermi liquid. This behavior is best pronounced in the vicinity of interaction-driven (Mott-like) metal-insulator transitions, where the T^* decreases, while the resistivity maximum ρ_{max} increases. Here we show that, in this regime, the entire family of resistivity curves display a characteristic scaling behavior $\rho(T)/\rho_{max} \approx F(T/T_{max})$, while the ρ_{max} and $T_{max} \sim T^*$ assume a powerlaw dependence on the quasi-particle effective mass m^* . Remarkably, precisely such trends are found from an appropriate scaling analysis of experimental data obtained from diluted two-dimensional electron gases in zero magnetic fields. Our analysis provides strong evidence that inelastic electron-electron scattering – and not disorder effects – dominates finite temperature transport in these systems, validating the Wigner-Mott picture of the two-dimensional metal-insulator transition.

12:27PM Q5.00007 Finite-size effects in transport data from Quantum Monte Carlo simulations, RAIMUNDO ROCHA DOS SANTOS, RUBEM MONDANI, Universidade Federal do Rio de Janeiro, KARIM BOUADIM, Ohio State University, THEREZA PAIVA, Universidade Federal do Rio de Janeiro — We have examined the behavior of the compressibility, of the dc-conductivity, and of the Drude weight as probes of the density-driven metal-insulator transition in the Hubbard model on a square lattice. These quantities have been obtained through determinantal quantum Monte Carlo simulations at finite temperatures on lattices up to 16×16 sites. While the compressibility and the dc-conductivity are known to suffer from ‘closed-shell’ effects due to the presence of artificial gaps in the spectrum (caused by the finiteness of the lattices), we have established that the former tracks the average sign of the fermionic determinant, and that a shortcut often used to calculate the conductivity may neglect important corrections. We have also performed systematic studies of the dependence of our data with the imaginary-time interval. Our analyses also show that, by contrast, the Drude weight is not too sensitive to finite-size effects, being much more reliable as a probe to the insulating state.

12:39PM Q5.00008 Universal transport near a continuous Mott transition in two dimensions, WILLIAM WITCZAK-KREMPA, University of Toronto, POUYAN GHAEMI, University of Illinois at Urbana-Champaign, TODADRI SENTHIL, MIT, YONG BAEK KIM, University of Toronto — We discuss the universal transport signatures near a zero-temperature continuous Mott transition between a Fermi liquid and a spin liquid in 2 spatial dimensions. This transition can be described using a slave-rotor field theory, where the electron is decomposed into a fermionic spinon and charge-carrying rotor, both interacting with an emergent $U(1)$ gauge field. The universal part of the non-zero temperature charge transport is determined by the dynamics of the charged rotors and is affected by the gauge fluctuations. Explicit predictions for the behavior of the electrical conductivity are made via the solution of a quantum kinetic equation using controlled approximations.

12:51PM Q5.00009 Dissipation-Induced Quantum Phase Transition in a Resonant Level¹, HENOK MEBRAHTU, IVAN BORZENETS, DONG E. LIU, HUAIXIU ZHENG, YURI BOMZE, Duke University, ALEX SMIRNOV, North Carolina State University, HAROLD BARANGER, GLEB FINKELSTEIN, Duke University — We measure conductance through a resonant level coupled to a dissipative environment, which suppresses tunneling rate at low energies. Our sample consists of a single-walled carbon nanotube quantum dot contacted by resistive metal leads that serve as the dissipative environment. We study the shape of the resonant conductance peak, with the expectation that its width and height, both dependent on the tunneling rate, will be suppressed at low temperatures. However, we observe distinct regimes, including a case where the resonant tunneling conductance reaches the unitary limit, despite the presence of dissipation. We discuss the implication of these findings for a dissipation-induced quantum phase transition and extract the scaling exponents.

¹Work supported by U.S. DOE

1:03PM Q5.00010 Collective excitations and low temperature transport properties of bismuth¹, PIOTR CHUDZINSKI, THIERRY GIAMARCHI, DPMC, University of Geneva, 24 Quai Ernest-Ansermet, CH-1211 Geneva 4, Switzerland — We examine the influence of collective excitations on the transport properties (resistivity and magneto-optical conductivity) for semimetals, focusing on the case of bismuth. We show, using a random-phase approximation (RPA), that the properties of the system are drastically affected by the presence of an acoustic-plasmon mode, which is a consequence of the presence of two types of carriers (electrons and holes) in this system. We find a crossover temperature T^* separating two different regimes of transport. At high temperatures where $T > T^*$, the Baber scattering explains quantitatively the dc resistivity experiments, while at low temperatures where $T < T^*$, the interactions of the carriers with this collective mode lead to a T^{-5} behavior of the resistivity. We examine other consequences of the presence of this mode. In particular a two-plasmon edge feature in the magneto-optical conductivity is predicted. We compare our results with the experimental findings on bismuth. We discuss the limitations and extensions of our results beyond the RPA, and examine the case of other semimetals such as $1T - TiSe_2$.

¹supported by MaNEP

1:15PM Q5.00011 Photo-excitation and relaxation dynamics in junction of double-exchange systems, WATARU KOSHIBAE, CMRG, RIKEN, Japan, NAOTO NAGAOSA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG, CERG, RIKEN, Japan, NOBUO FURUKAWA, ERATO-MF, Aoyama-Gakuin Univ., Japan — The photo-induced insulator-metal (I-M) transition is studied by the numerical simulation of real-time quantum dynamics of a double-exchange model. We find a characteristic multiplication of particle-hole (p-h) pairs by a p-h pair of high energy during the I-M transition. To examine the conversion from the p-h pairs into electric energy, we perform the numerical study on the junction systems combined by the double exchange models. The numerical results have been revealed including (i) the threshold behavior with respect to the intensity and energy of light, (ii) p-h pairs are well separated and pair annihilation is suppressed, (iii) enhancement of collected carrier by meta-stability of I-M transition.

1:27PM Q5.00012 Photo excited state in spin-charge coupled correlated electron system, SUMIO ISHIHARA, YU KANAMORI, Department of Physics, Tohoku University, HIROAKI MATSUEDA, Sendai National College of Technology, JUN OHARA, Department of Physics, Tohoku University — Recent ultrafast optical techniques open up a new frontier for research of the phase transition. Photo-induced phase is transient and highly nonequilibrium. photo-induced phenomena in correlated electron systems offer large possibility of new hidden phases which do not realize in the thermal equilibrium state, and prompt several theoretical challenges. In this talk, I will talk about recent our theoretical results for the photo-induced phase transition in correlated electron systems. We study the photo-induced spin state change in itinerant correlated electron system, motivated from the experiments in perovskite cobaltites [1]. The effective models before and after photon-pumping are derived from the two-orbital Hubbard model and are analyzed by the exact diagonalization method. When a photon is introduced in the low-spin band insulator, we found a spin-polarized bound state of photo-excited hole and the high-spin state. This bound state directly reflects the optical pump-probe spectra. These results well explain the recent femtosecond spectroscopy experiments in perovskite cobaltites We also show the unusual double-exchange interaction in photo excited state.

1:39PM Q5.00013 Non-equilibrium steady state of field-driven strongly correlated electrons¹, WOO-RAM LEE, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea, JONG EUN HAN, Department of Physics, State University of New York at Buffalo, Buffalo, New York 14260, USA, KWON PARK, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea — We theoretically study the nature of non-equilibrium steady state of strongly correlated electrons on lattices under the influence of a static electric field. We describe the dynamics of steady state by the Floquet theory, and the electron correlation by the dynamical mean-field theory, respectively. We find that the steady-state current in a closed system is characterized by the Bloch oscillation in the metallic regime, while it vanishes in the Mott-insulating regime. Importantly, the coherent contribution to the current can be captured by measuring the quasiparticle weight in the local spectral density as in equilibrium. Based on these criteria, we draw the non-equilibrium phase diagram as a function of the strength of electric field and the on-site interaction at zero temperature. *References: [1] A. V. Jura, J. K. Freericks, and Th. Pruschke, Phys. Rev. Lett. 101, 196401 (2008); [2] N. Tsuji, T. Oka, and H. Aoki, Phys. Rev. B 78, 235124 (2008).

¹We thank Korea Institute for Advanced Study for providing computing resources (KIAS Linux Cluster System) for this work.

1:51PM Q5.00014 Dynamical DMRG study of non-linear optical response in one-dimensional dimerized Hubbard model with nearest neighbor Coulomb interaction and alternating on-site potential, SHIGETOSHI SOTA, TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto, Japan, SERGUEI BRAZOVSKII, LPTMS-CNRS, University Paris-Sud, Orsay, France — The optical response of organic compounds has been attracting much attention. The one of the reasons is the huge non-linear and ultrafast optical response [K. Yamamoto *et. al.*, J. Phys. Soc. Jpn. **77**, 074709(2008)]. In order to investigate such optical properties, we carry out dynamical DMRG calculations to obtain optical responses in the 1/4-filled one-dimensional Hubbard model including the nearest neighbor Coulomb interaction and the alternating electron hopping. The charge gap [S. Nishimoto, M. Takahashi, and Y. Ohta, J. Phys. Soc. Jpn. **69**, 1594(2000)] and the bound state [H. Benthien and E. Jeckelmann, Eur. Phys. J. B **44**, 287(2005)] in this model have been discussed based on DMRG calculations. In the present study, we introduce an alternating on-site potential giving the polarization in the system into the dimerized Hubbard model, which breaks the reflection symmetry of the system. In this talk, we discuss the obtained linear and the 2nd order non-linear optical susceptibility in order to make a prediction for non-linear optical experiments in the future.

2:03PM Q5.00015 Non-Kondo mechanism of resistivity upturn in a spin-ice Kondo lattice model, YUKITOSHI MOTOME, Dept. Appl. Phys., Univ. of Tokyo, MASAFUMI UDAGAWA, Dept. Appl. Phys., Univ. of Tokyo, MPI-PKS, Dresden, HIROAKI ISHIZUKA, Dept. Appl. Phys., Univ. of Tokyo — Ice rule is a configurational constraint observed in a broad range of systems in which two-state variables are defined at the vertices of a pyrochlore lattice. The constraint enforces the so-called 'two-in two-out' configuration; two out of four neighboring sites within each tetrahedron are in the opposite state to the other two. Under this peculiar local constraint, the system remains disordered, whereas the ground state is characterized by macroscopic degeneracy with a hidden gauge structure. Recent experiments on pyrochlore metallic oxides have promoted interest in itinerant electrons coupled with such ice-rule type localized moments. Here we investigate how electronic and transport properties are affected by the coupling to the spin ice by applying a cellular dynamical mean-field theory to a spin-ice type Kondo lattice model. We found that a spin-ice liquid state emerges in a wide temperature range at low electron density, in which two-in two-out local correlation well develops in the absence of long-range ordering. In this spin liquid state, the resistivity shows an upturn because of an anomalous scattering of electrons by the local spin-ice type correlation. The details of this non-Kondo resistivity upturn will be discussed in relation with experiments in pyrochlore oxides.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q6 DMP: Carbon Nanotubes: Electronic and Thermal Properties 206B

11:15AM Q6.00001 Ultra-short single-wall carbon nanotube NEMS transistors, ANDREW C. MCRAE, JOSHUA O. ISLAND, VAHID TAYARI, SERAP YİĞEN, A.R. CHAMPAGNE, Department of Physics, Concordia University, Montreal, Canada — We study electron transport in clean suspended single-wall carbon nanotube (SWCNT) transistors hosting a single quantum dot (QD) ranging in length from a few tens of nm down to ≈ 3 nm. To fabricate these ultra-short QD transistors, we align narrow gold bow-tie junctions on top of individual SWCNTs and suspend the devices. We then use a feedback-controlled electromigration to break the gold junctions and expose nm-sized sections of the SWCNTs. We measure electron transport in these devices at low temperature and show that they form clean and tunable quantum dot transistors. We observe QD excited states which correspond to both the stretching and flexural vibronic modes. The out-of-plane vibron resonances approach the THz range, and show that these ultra-short suspended transistors are promising candidates to develop highly sensitive NEMS and explore the strong electron-vibron coupling regime.

11:27AM Q6.00002 Measurement of intrinsic resistivity of individual single walled carbon nanotubes with known-chirality, MITSUhide TAKEKOSHI, VIKRAM DESHPANDE, ZHENGYI ZHANG, Columbia University, YUHEI MIYAUCHI, Kyoto University, TONY HEINZ, JAMES HONE, PHILIP KIM, Columbia University — We report the electrical resistivity measured on individual single walled nanotubes (SWNTs) whose atomic structures are characterized by Rayleigh and Raman spectroscopy. Since electrical transport of SWNTs on substrates is predominantly limited by surface polar phonon from substrate at elevated temperatures, intrinsic transport properties of SWNTs limited by nanotube phonons remained to be probed experimentally. Here we present electrical transport measurement of long suspended individual SWNTs with exactly assigned atomic structures. SWNTs are grown by the chemical vapor deposition method on pre-patterned electrodes and their exact chiral indices are obtained using Rayleigh and Raman spectroscopy. We investigate temperature dependent resistivity of metallic SWNTs in the diffusive regime. We will discuss the chirality dependence of the electron-acoustic phonon interaction inferred from the temperature dependent intrinsic resistivity of SWNTs.

11:39AM Q6.00003 Probing Magnetic Susceptibility Anisotropy of Large-Diameter Armchair Carbon Nanotubes via Magnetic Linear Dichroism Spectroscopy, ERIK HAROZ, JUNICHIRO KONO, Rice University, Dept. of ECE, THOMAS SEARLES, Morehouse Univ., Dept. of Physics, XIAOMIN TU, MING ZHENG, JEFFREY FAGAN, National Institute of Standards & Technology, Polymer Division, STEPHEN MCGILL, DMITRY SMIRNOV, National High Magnetic Field Laboratory — We studied magnetic susceptibility anisotropy, via magnetic linear dichroism spectroscopy, of aqueous suspensions of single-walled carbon nanotubes in high magnetic fields up to 22T using a unique magnet system (Split-Florida Helix magnet). Specifically, we measured magnetic susceptibility anisotropies, $\Delta\chi$, of several armchair species ranging from (5,5)-(13,13) at room temperature over an excitation wavelength range of 400-900 nm. For large diameter armchairs such as (12,12) and (13,13), we have observed some of the strongest alignment in a static magnetic field due to their large diameters. Results will be discussed in comparison with detailed calculations involving the Aharonov-Bohm effect.

11:51AM Q6.00004 Helical modes and Majorana fermions in carbon nanotubes, JELENA KLINOVAJA, MANUEL SCHMIDT, BERND BRAUNECKER, DANIEL LOSS, Department of Physics, University of Basel — We derive an effective low-energy theory for metallic (armchair and nonarmchair) single-wall nanotubes in the presence of an electric field perpendicular to the nanotube axis, and in the presence of magnetic fields, taking into account spin-orbit interactions and screening effects on the basis of a microscopic tight-binding model [1,2]. The interplay between electric field and spin-orbit interaction allows us to tune armchair nanotubes into a helical conductor in both Dirac valleys. Metallic nonarmchair nanotubes are gapped by the surface curvature, yet helical conduction modes can be restored in one of the valleys by a magnetic field along the nanotube axis. If in proximity with a superconductor, helical modes give rise to Majorana bound states. Furthermore, we discuss electric dipole spin resonance in carbon nanotubes, and find that the Rabi frequency shows a pronounced dependence on the momentum along the nanotube.

12:03PM Q6.00005 Extracting Diameter and Chirality Dependences of Optical and Electronic Properties of Semiconducting Single-Wall Carbon Nanotubes from First-Principles Calculations

, RODRIGO B. CAPAZ, Universidade Federal do Rio de Janeiro, Brazil, JACK DESLIPPE, Lawrence Berkeley National Laboratory, STEVEN G. LOUIE, U. C. Berkeley and Lawrence Berkeley National Laboratory — First-principles methods based on the combination of density-functional theory (DFT) for ground-state properties, GW approximation for quasiparticle properties and Bethe-Salpeter equation (BSE) for optical properties represent the state-of-art for accurate and reliable calculations of optical and electronic properties of solids and molecules. For semiconducting carbon nanotubes (CNTs), they have been applied successfully to selected small-diameter tubes. In this work, we systematically calculate such properties for all zig-zag semiconducting single-wall carbon nanotubes with diameters ranging from (10,0) to (20,0) CNTs, allowing us to extract in a reliable way the diameter and chirality dependence of many properties, such as: (i) optical transition energies; (ii) quasiparticle band gaps; (iii) exciton binding energies; (iv) bright-dark exciton splittings; (v) excited exciton states properties; (vi) transverse-polarized exciton states properties; (vii) electron and hole effective masses (and therefore excitonic reduced masses). All properties are described with good accuracy by diameter- and chirality-dependent analytical formulas, with parameters extracted from the first-principles calculations.

12:15PM Q6.00006 Modeling the Thermal Conductivity of Nanocomposites Using Monte-Carlo Methods and Realistic Nanotube Configurations¹

, KHOA BUI, DIMITRIOS PAPAVALASSILOU, The University of Oklahoma — The effective thermal conductivity (K_{eff}) of carbon nanotube (CNT) composites is affected by the thermal boundary resistance (TBR) and by the dispersion pattern and geometry of the CNTs. We have previously modeled CNTs as straight cylinders and found that the TBR between CNTs ($TBR_{CNT-CNT}$) can suppress K_{eff} at high volume fractions of CNTs [1]. Effective medium theory results assume that the CNTs are in a perfect dispersion state and exclude the $TBR_{CNT-CNT}$ [2]. In this work, we report on the development of an algorithm for generating CNTs with worm-like geometry in 3D, and with different persistence lengths. These worm-like CNTs are then randomly placed in a periodic box representing a realistic state, since the persistence length of a CNT can be obtained from microscopic images. The use of these CNT geometries in conjunction with off-lattice Monte Carlo simulations [1] in order to study the effective thermal properties of nanocomposites will be discussed, as well as the effects of the persistence length on K_{eff} and comparisons to straight cylinder models. **References** [1] K. Bui, B.P. Grady, D.V. Papavassiliou, Chem. Phys. Lett., 508(4-6), 248-251, 2011 [2] C.W. Nan, G. Liu, Y. Lin, M. Li, App. Phys. Lett., 85(16), 3549-3551, 2006

12:27PM Q6.00007 Computational study of the thermal conductivity of defective carbon nanostructures¹

, ZACHARIAS FTHENAKIS, DAVID TOMANEK, Michigan State University — We use molecular dynamics simulations to study the role of defects on the thermal conductivity in low-dimensional graphitic nanostructures such as schwarzites (3D), graphene (2D), carbon nanotubes and graphene nanoribbons (1D). Since the simulations are very demanding due to the very long phonon mean free path, we describe forces acting on carbon atoms by a parameterized valence force field. Our calculations make use of the non-equilibrium molecular dynamics technique, which incorporates the constant-temperature Nose-Hoover thermostat and non-equilibrium driving forces, which mimic the effect of the heat flow. We study different types of defects, including vacancies and isotope impurities, and show that their importance changes with changing dimension of the system.

12:39PM Q6.00008 Near-field heat transfer between an array of SWNTs and a quartz substrate¹

, ANDREI NEMILENTSAU, SLAVA ROTKIN, Department of Physics, Lehigh University — The near-field heat transfer between a quartz substrate and a sparse array of SWNTs oriented normal to the substrate was studied theoretically. The heat power transferred from the hot quartz substrate to the cold SWNTs was expressed through the electric field Green tensor of the system using the fluctuation-dissipation theorem. The integral equation for the Green tensor was obtained and solved numerically. The spectra of the transferred power were calculated and the pronounced resonance lines in the spectra were demonstrated at the frequencies of the polariton resonances in the quartz and antenna resonances of the surface plasmons in the SWNTs. The dependence of the transferred power on separation between the SWNTs and the substrate and on the SWNTs lengths in the array was also studied.

¹Supported by DoD (AFOSR # FA9550-11-1-0185).

12:51PM Q6.00009 Ab initio studies of mechanical, electric, and magnetic properties of functionalized carbon nanotubes¹

, KAROLINA MILOWSKA, MAGDALENA BIROWSKA, JACEK A. MAJEWSKI, University of Warsaw — We present results of extensive theoretical studies of mechanical, electric, and magnetic properties of functionalized carbon nanotubes (CNTs). Our studies are based on the ab initio calculations in the framework of the density functional theory. We have performed calculations for various metallic and semiconductor single wall CNTs, functionalized with simple organic molecules such as OH, COOH, NH_n, CH_n and metals, Al, Fe, Ni, Cu, Zn, and Pd. We have determined the stability of the functionalized CNTs, their elastic moduli, conductance, and magnetic moments (in the case of CNTs decorated with magnetic ions). These studies shed light on physical mechanisms governing the binding of the adsorbed molecules and also provide valuable quantitative predictions that are of importance for design of novel composite materials and functional devices. In particular, we find out that the Young's modulus of functionalized CNTs is smaller than in the case of bare CNTs, however it is large enough to provide a strong enforcement of composites. The functionalization with molecules leads also to the metallization of semiconducting CNTs, being relevant in the context of CNT interconnects, whereas the functionalization with metals might be used to cut CNTs into ribbons.

¹The studies were carried out within the SiCMAT Project financed under the European Funds for Regional Development (Contract No. UDA-POIG.01.03.01-14-155/09).

1:03PM Q6.00010 Nanotube based engine

, OLEG SHKLYAEV, ERIC MOCKENSTURM, Department of Mechanical and Nuclear Engineering, The Pennsylvania State University, University Park, PA, 16802-6300, USA, VIN CRESPI, Department of Physics and Materials Research Institute, The Pennsylvania State University, University Park, PA, 16802-6300, USA — We discuss a mechanism for converting electrical energy into translational motion using a variable-shape bistable carbon nanotube. Clamping one tube end open and the other one closed, we use an applied voltage to switch the tube between mostly collapsed and mostly inflated shapes. Devices based on such a double-pinned tube geometry can operate as a voltage-controlled constant-force spring, a charge-controlled harmonic spring, or an electromechanical engine performing work by coupling to a propagating collapsed/inflected transition region. Making an analogy to ideal-gas thermodynamics, constant-voltage, constant-charge, and constant-geometry operational regimes correspond to isothermal, adiabatic and isochoric processes. Constant-voltage, constant-charge, and constant-geometry processes coupled can be combined into cycles analogous to those of a heat engine. Unlike a heat engine, the tube bistability enables it to collect useful work on both inflation and collapse motions, thus eliminating the need for external forces to restore the system to its initial state during the operational cycle.

1:15PM Q6.00011 Influence of temperature and adsorbates on a carbon nanotube resonator by molecular dynamics simulations, HEEYUEN KOH, JAMES CANNON, SHIGEO MARUYAMA, JUNICHIRO SHIOMI, the University of Tokyo — The bending modes of carbon nanotube have been studied for ultralow mass and force sensing and its tunable resonance frequency. On the other hand, the nonlinear damping of flexural mode has been shown to be vulnerable to temperature and adsorbates. For this reason, we have studied the interaction between mechanical and thermal characteristics in a carbon nanotube cantilever resonator observing the phase space trajectories, strain-stress distributions, and lattice vibrational spectra for various temperatures and adsorbate conditions. The calculation was based on molecular dynamics simulations using the REBO potential, where a carbon nanotube was excited by sinusoidal mechanical forcing at a tube end with constant-temperature boundary condition. The result confirms that the localized strain distribution is in agreement with previous high-resolution transmission electron microscopy result. Based on the simulations, the dynamic Young's modulus and the damping coefficient will be extracted in the frequency domain for different nanotube length and chirality, and will be compared with the continuum theories. In addition, the interaction between the first resonance mode and the background phonons will be discussed based on the obtained dissipated thermal energy and the phonon energy spectra.

1:27PM Q6.00012 Electron Spin Resonance as a route to Spin-Gap detection in Carbon Nanotubes, DARRYL H. NGAI, ANDRE' LECLAIR, EUN-AH KIM, Cornell University — The recent observation of a charge-neutral excitation gap in ultraclean carbon nanotubes¹ raises the intriguing possibility of a phase with gapless charge spectrum and gapped spin spectrum: the Luther-Emery liquid. We note that ESR would be an ideal probe to directly test whether the observed gap is a spin-gap, as it probes the non-local correlations of conduction electron spins. We focus on the Luther-Emery point ($K_s = 1/2$, also known as free fermion point) where an explicit calculation of relevant spin-spin correlation function is possible, to calculate the ESR signal in a Luther-Emery liquid. At high frequencies of $\omega > 2\Delta_s$ where Δ_s is the spin-gap, the ESR signal of the Luther-Emery liquid will exhibit a second peak at magnetic fields away from the resonance condition of $B = \omega/\mu_B g K_s$. We discuss how to measure the spin-gap from the location of this additional peak as a function of applied field strength.

¹V. V. Deshpande *et al.*, Science **323**, 106 (2009)

1:39PM Q6.00013 Coherent non-local transport in quantum wires with strongly coupled electrodes¹, YANFEI YANG, GEORGY FEDOROV², PAOLA BARBARA, Department of Physics, Georgetown University, Washington, DC, SERHII SHAFRANIUK, Department of Physics and Astronomy, Northwestern University, Evanston, IL, BENJAMIN COOPER, RUPERT LEWIS, CHRISTOPHER LOBB, Department of Physics, CNAM and JQI, University of Maryland, College Park, MD — We report a one-dimensional non-local experiment, where the conductance of a section of carbon nanotube shows regular oscillations due to coherent and ballistic transport in an adjacent section. This occurs in spite of wide strongly coupled contact electrodes, which are expected to divide the nanotube into independent sections. Our simulations show that the electrodes form shallow and wide barriers, which maintain quantum coherence between the adjacent sections.

1:51PM Q6.00014 Nanofissure formation during selective breakdown of m-SWNT in an aligned array, UDAI BHANU, SHASHANK SHEKHAR, Nanoscience Technology Center, and Department of Physics, University of Central Florida, SAIFUL I. KHONDAKER, Nanoscience Technology Center, and Department of Physics, and School of Electrical Engineering and Computer Science University of Central Florida — Selective removal of metallic single walled carbon nanotubes (m-SWNT) in an aligned array is needed for restoring semiconducting properties and better device performance. The selective removal is done via electrical breakdown of m-SWNT while applying a large gate voltage to preserve semiconducting SWNT. In this work, we show using electrical measurements and scanning electron microscopy imaging that in a sufficiently dense array, not only the m-SWNT breaks down but also s-SWNT breaks down in a correlated fashion giving rise to a nano fissure pattern. This is in contrast to the established understanding that SWNTs are broken in a random fashion. The origin of the correlated breakdown is due to the electrostatic field of the broken nanotubes that produces locally inhomogeneous current and Joule heating distributions in the neighboring intact nanotubes triggering their breakdowns in the vicinity of the broken nanotubes

2:03PM Q6.00015 An optically pumped InGaAsP/InP quantum dot rolled-up microtube laser, PABLO BIANUCCI, Department of Engineering Physics, École Polytechnique de Montréal, Montreal QC, H3C 3A7, M. HADI TAVAKOLI DASTJERDI, SHOUVIK MUKHERJEE, MEHRDAD DJAVID, Department of Electrical Engineering, McGill University, Montreal QC, H3A 2A7, PHILIP POOLE, Institute for Microstructural Sciences, National Research Council, Ottawa, Ontario K1A 0R6, Canada, ZETIAN MI, Department of Electrical Engineering, McGill University, Montreal QC, H3A 2A7 — Rolled-up quantum dot microtubes are a promising candidate for light sources in integrated photonics. We have fabricated InGaAsP/InAs quantum dot rolled-up microtubes from InGaAsP strained bilayers with embedded InAs quantum dots (grown by chemical beam epitaxy). In room-temperature photoluminescence experiments we have observed resonant-mode emission with wavelengths in the telecom range. This resonant emission is consistent with whispering gallery modes. At a temperature of 82 K, we have demonstrated multi-mode lasing under continuous wave optical pumping. We estimate an ultra-low lasing threshold near 1.25 μ Ws of absorbed optical power.

Wednesday, February 29, 2012 11:15AM - 2:15PM –
Session Q7 DMP DCOMP: Focus Session: Computational Design of Materials: Graphene - Strain, defect and interface engineering 207

11:15AM Q7.00001 Formation of hydrogenated graphene nanoripples by strain engineering and directed surface self-assembly¹, ZHENGFEI WANG, YU ZHANG, FENG LIU, University of Utah, Department of Materials Science and Engineering, FENG LIU'S GROUP TEAM — We propose a class of semiconducting graphene-based nanostructures: hydrogenated graphene nanoripples (HGNRs), based on continuum-mechanics analysis and first-principles calculations. They are formed via a two-step combinatorial approach: first by strain-engineered pattern formation of graphene nanoripples, followed by a curvature-directed self-assembly of H adsorption. It offers a high level of control of the structure and morphology of the HGNRs, and hence of their band gaps, which share common features with graphene nanoribbons. A cycle of H adsorption (desorption) at (from) the same surface locations completes a reversible metal-semiconductor-metal transition with the same band gap.

¹This work was supported by DOE-BES program.

11:27AM Q7.00002 Engineering electronic properties of armchair graphene nanoribbons using strain and functional species, XIHONG PENG, FU TANG, SELINA VELASQUEZ, ANDREW COPPLE, Arizona State University — First principles density-functional theory calculations were performed to study effects of strain, edge passivation, and surface functional species on structural and electronic properties. Particularly band gap and work function, of armchair graphene nanoribbons (AGNRs), are addressed. It was found that the band gap of the O-passivated AGNRs experiences a direct-to-indirect transition with sufficient tensile strain. The indirect band gap reduces to zero with further increased strain. The work function was found to increase with uniaxial tensile strain while decreasing with compression. The variation of the work function under strain is primarily due to the shift of the Fermi energy with strain. For AGNRs with edge carbon atoms passivated by oxygen, the work function is higher than that of nanoribbons with edge passivated by hydrogen under a moderate strain. The difference between work functions in these two edge passivations is enlarged (reduced) under a sufficient tensile (compressive) strain. Furthermore, the effect of surface species decoration, such as H, F, or OH with different covering density, was investigated. It was found the work function varies with the type and coverage of surface functional species. F and OH decoration increase the work function while H decreases it. The surface functional species were decorated on either one side or both sides of AGNRs. The difference in the work functions between one-side and two-side decorations was found to be relatively small, which may suggest the introduced surface dipole plays a minor role.

11:39AM Q7.00003 Electronic Band Engineering of Epitaxial Graphene by Atomic Intercalation, THUSHARI JAYASEKERA, Department of Physics, Southern Illinois University, Carbondale, IL, 62901, ANDREAS SANDIN, SHU XU, Department of Physics, North Carolina State University, Raleigh, NC 27695, VIRGINIA WHEELER, D.K. GASKILL, U.S. Naval Research Laboratory, Washington, DC 20375, J.E. ROWE, Department of Physics, North Carolina State University, Raleigh, NC 27695, K.W. KIM, Department of Electrical and Computer Engineering, North Carolina State University, Raleigh, NC 27695, DANIEL B. DOUGHERTY, M. BUONGIORNO NARDELLI, Department of Physics, North Carolina State University, Raleigh, NC 27695 — Using calculations from first principles, we have investigated possible ways of engineering the electronic band structure of epitaxial graphene on SiC. In particular, intercalation of different atomic species, such as Hydrogen, Fluorine, Sodium, Germanium, Carbon and Silicon is shown to modify and tune the interface electronic properties and band alignments. Our results suggest that intercalation in graphene is quite different from that in graphite, and could provide a fundamentally new way to achieve electronic control in graphene electronics.

11:51AM Q7.00004 Interplay of Defects, Magnetism, Ripples and Strain in Graphene¹, ELTON J.G. SANTOS, Department of Physics and School of Engineering and Applied Sciences, Harvard University, 17 Oxford Street, Cambridge 02138, MA, ANDRES AYUELA, DANIEL SANCHEZ-PORTAL, Centro de Fisica de Materiales MFC, CSIC-UPV/EHU and Donostia International Physics Center, Paseo Manuel de Lardizabal 4/5, San Sebastian, 20018, Spain — We present a comprehensive study based on first-principles calculations about the interplay of four important ingredients on the electronic structure of graphene: defects + magnetism + ripples + strain. So far they have not been taken into account simultaneously in a set of ab initio calculations. Furthermore, we focus on the strain dependence of the properties of carbon monovacancies, with special attention to magnetic spin moments. We demonstrated that such defects show a very rich structural and spin phase-diagram with many spin solutions as function of strain. At zero strain the vacancy shows a spin moment of 1.5 Bohrs that increases up to 2 Bohrs with stretching. Changes are more dramatic under compression: the vacancy becomes non-magnetic under a compression larger than 2%. This transition is linked to the structural modifications associated with the formation of ripples in the graphene layer. Our results suggest that such interplay could have important implications for the design of future spintronics devices based on graphene derivatives, as for example a spin-strain switch based on vacancies.

¹We acknowledge support from Basque Departamento de Educacion and the UPV/EHU (Grant No. IT-366-07), the Spanish Ministerio de Educacion y Ciencia (Grant No. FIS2010-19609-CO2-02) and the ETORTEK program.

12:03PM Q7.00005 Spin switching in organic molecules by strain engineering in graphene¹, BIPLAB SANYAL, SUMANTA BHANDARY, Department of Physics and Astronomy, Uppsala University, SAURABH GHOSH, Cornell University, USA, HEIKE HERPER, HEIKO WENDE, University of Duisburg-Essen, Germany, OLLE ERIKSSON, Department of Physics and Astronomy, Uppsala University — One of the primary objectives in molecular nano-spintronics is to manipulate the spin states of organic molecules with a d-electron center, by suitable external means. Here, we demonstrate by first principles density functional calculations, as well as second order perturbation theory, that a strain induced change of the spin state, from $S=1 \rightarrow S=2$, takes place for an iron porphyrin (FeP) molecule deposited at a divacancy site in a graphene lattice. The process is reversible in a sense that the application of tensile or compressive strains in the graphene lattice can stabilize FeP in different spin states, each with a unique saturation moment and easy axis orientation. The effect is brought about by a change in Fe-N bond length in FeP, which influences the molecular level diagram as well as the interaction between the C atoms of the graphene layer and the molecular orbitals of FeP. We propose that the spin switching should be detected by x-ray magnetic circular dichroism experiments through the contributions from spin dipole and magnetic anisotropy.

¹We gratefully acknowledge financial support from STINT Institutional Grant for Young Researchers, Swedish Research Council (VR) and a KOF grant from Uppsala University and SNIC for supercomputing allocations.

12:15PM Q7.00006 The magnetism in graphene under strain, YI CHEN CHANG, STEPHAN HAAS, University of Southern California, COMPUTATIONAL CONDENSED MATTER THEORY GROUP TEAM — We theoretically study the magnetic features in graphene dot under mechanical deformation using the mean field Hubbard model. The edge local magnetic moment (ELMM) is considerably modified in accordance with an effective quantum well originating from a strain-induced gauge field. Applying a uniaxial strain along the zigzag or armchair directions enhances or dampens the ELMM due to the development of the edge quantum wells. Whereas a circular arc bending deformation is applied, the inner and outer edge display ELMM caused by nonuniform gauge field, a direct consequence of the presence of the bulk localized states. These states suggest that an effective single well potential is introduced by a nonuniform pseudo-magnetic field.

12:27PM Q7.00007 Vacancy-induced order-to-disorder transition in single-layer graphene, CORINNE CARPENTER, ASHWIN RAMASUBRAMANIAM, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — Defect engineering provides a potential route for tuning the mechanical, electronic, and chemical properties of graphene. While individual defects in single-layer graphene have been investigated in much detail, the outcomes of collective interactions of multiple defects remain elusive. In this work, we address the collective interaction of populations of vacancies in single-layer graphene using classical molecular-dynamics simulations based on reliable bond-order potentials; we examine random vacancy distributions with the vacancy concentration and temperature being the key parameters in the analysis. We demonstrate that a crystalline-to-amorphous structural transition occurs as the vacancy concentration in single-layer graphene increases beyond a critical level; the transition leads to complete loss of long-range order in the graphene layer. The onset of this order-to-disorder transition typically occurs over the vacancy concentration range from 10 to 20% and is independent of the details of the interatomic interactions in the classical potentials employed. We present a systematic parametric study of the phenomenon and discuss the implications of our findings for the mechanical and electronic properties of single-layer graphene.

12:39PM Q7.00008 Two magnetic impurities in graphene¹, FEI-MING HU, Aalto University, School of Science, Finland, JAME GUBERNATIS, Los Alamos National Laboratory, Los Alamos, New Mexico, USA, HAI-QING LIN, Beijing Computational Science Research Center, Beijing, China and The Chinese University of Hong Kong, Hong Kong, China, RISTO NIEMINEN, Aalto University, School of Science, Finland — We theoretically investigate two magnetic impurities in graphene. We mainly study the indirect interaction between the two magnetic impurities mediated by conducting electrons, which is so called RKKY interaction. The spin-spin and charge-charge correlation functions are calculated by quantum Monte Carlo simulations when the Fermi energy of the system is changed by gate voltage. The spectral density of the two impurities is also studied by maximum entropy methods.

¹We thank the CSC in Finland for computer resources.

12:51PM Q7.00009 Power-Law Correlated Disorder in Graphene and Square Nanoribbons¹, NANCY SANDLER, GREG PETERSEN, Ohio University — Two dimensional metal-insulator transitions have remained an active topic in condensed matter physics do to the lack of a general model that can predict when an MIT occurs. With the creation of truly 2D crystals and nanostructures, the question has become increasingly relevant. Though initially predicted to not contain a MIT transition, the inclusion of electron-electron interactions and/or spatial disorder can drive a MIT in some 2D systems. In the case of graphene, correlated ripples are present even when the nanoribbons are freestanding and can have an effect on the transport properties while electron-electron interactions are normally considered negligible. To explore the effect of ripples, we model graphene with a long-range power-law spatial correlation of the form $\langle \epsilon_i^2 \rangle = 1/(1 + |\vec{r}_i/a|)^\alpha$ where ϵ_i , $\vec{r}$, a , and α are the on-site energy, position, lattice constant, and strength of the correlation respectively. It should be noted that much work has been completed on short-range correlations but little on truly long-range correlations. We also present our finding for the square lattice for comparison.

1:03PM Q7.00010 Thermally-driven Isotope Separation Across Nanoporous Graphene¹, JOSHUA SCHRIER, Haverford College — Experiment and theory indicate that a single graphene sheet is impermeable to gases even as small as helium; pores are required for transmission of atoms and molecules. Nanoporous forms of graphene, such as two-dimensional polyphenylene (2D-PP), consist of a regular array of sub-nanometer pores which can be used for separating atoms and molecules by size. Because the nanoporous graphene barrier is only an atom-thick, quantum tunneling plays a role in the transmission of atoms through the nanoporous barrier, even at room temperature. This talk describes how the mass-dependence of the tunneling, combined with a temperature gradient, can be used to separate isotope mixtures under conditions where classical transmission cannot. Using transition state theory, we show that the zero-point and tunneling contributions lead to isotopic separations in opposite directions with respect to the temperature gradient. We examine the separation of ³He/⁴He across a 2D-PP membrane under modest temperature and pressure conditions. We will also describe 2D-PP bilayer structures that yield resonant tunneling of helium atoms, and new nanoporous graphene structures suitable for separating heavier noble-gas isotopes.

1:15PM Q7.00011 Phonon instabilities in graphene¹, KLAUS ZIEGLER, Universitaet Augsburg, Germany, EUGENE KOGAN, Bar-Ilan University, Israel — We study the thermal distribution of phonons in graphene and compare in-plane and out-of-plane contributions with a focus on two in-plane modes that represent intervalley scattering. Due to the two electronic bands there are also two out-of-plane phonon modes with respect to the two sublattices. The electron-phonon interaction softens the phonon modes with a tendency to create instabilities for a sufficiently large electron-phonon coupling. The instabilities are characterized by phase transitions, where one of the out-of-plane mode undergoes an Ising transition by spontaneously breaking the sublattice symmetry. The in-plane modes undergo a Berezinskii-Kosterlitz-Thouless transition. We calculate the critical points of the instabilities, the renormalization of the phonon frequencies and the phonon frequency splitting for in-plane modes. The possibility to observe these instabilities in doped graphene and their consequences for transport are discussed.

1:27PM Q7.00012 Electronic Properties of Epitaxial Graphene on Si(111)-7×7 and 3CS-SiC(100) Substrates, SHU XU, North Carolina State University, THUSHARI JAYASEKERA, Southern Illinois University, MARCO BUONGIORNO NARDELLI, North Carolina State University — The synthesis of epitaxial graphene is an attractive method for industrial-scale fabrication and mass production of graphene-based electronic devices. Recently, efforts of epitaxial growth of graphitic carbon films on Si(111)-7×7 and 3CS-SiC(100) substrates have been undertaken in order to explore new potential substrates compatible with conventional Si technology. In this talk, we will discuss the electronic properties of epitaxial graphene on Si (111)-7×7 and 3CS-SiC(100) substrates using calculations from first principles based on Density Functional Theory. In particular, we found that a single graphene layer on Si(111)-7×7 displays ripples of about 0.5 Å and shows an n type electronic behavior. We also calculated the band structures for a graphene bilayer on 3CS-SiC(100) surface with different stacking sequences. While AA stacking on Si face and turbostratic stacking on C face show n type behavior, turbostratic stacking on Si face and AA stacking on C face show p type behavior. On both faces, the first carbon plane is covalently bonded to the substrate and serves as a buffer layer similarly to the graphene/6H-SiC(0001) system previously studied.

1:39PM Q7.00013 Graphene-nickel interface: hybridization and magnetization, TESFAYE ABTEW, BI-CHING SHIH, PEIHONG ZHANG, University at Buffalo, The State University of New York — The unique properties of graphene have opened up a new avenue for fundamental research as well as technological applications. Whereas the in-plane sp^2 bonding is primarily responsible for the overall structural stability and mechanical strength of graphene, the out-of-plane $pp-\pi$ states control its transport and interfacing properties. In this talk, we present a first principles study of the single layer graphene/Ni(111) interface. We discuss how hybridization between the carbon $pp-\pi$ and nickel d orbitals modifies the electronic and magnetic properties of the interface.

We acknowledge the computational support provided by the Center for Computational Research at the University at Buffalo, SUNY. This work is supported by the Department of Energy under Grant No. DE-SC0002623 and by the National Science Foundation under Grant No. DMR-0946404.

1:51PM Q7.00014 Correlated magnetic states in domain and grain boundaries in graphene¹

, RICARDO W. NUNES, SIMONE S. ALEXANDRE, U. F. Minas Gerais - Brazil, ALINE D. LUCIO, U. F. Lavras - Brazil, ANTONIO H. CASTRO NETO, Graphene Research Centre and Physics Dept. National Univ. Singapore and Physics Dept. Boston Univ. — Ab initio calculations indicate that while the electronic states introduced by grain boundaries in graphene are only partially confined to the defect core, a domain boundary introduces states near the Fermi level that are very strongly confined to the core of the defect, and that display a ferromagnetic ground state. The domain boundary is fully immersed within the graphene matrix, hence this magnetic state is protected from reconstruction effects that have hampered experimental detection in the case of ribbon edge states. Furthermore, our calculations suggest that charge transfer between one-dimensional extended defects and the bulk in graphene is short ranged for both grain and domain boundaries. <http://arxiv.org/abs/1109.6923>

2:03PM Q7.00015 A Nanocluster Based Study of Silicon Carbide Nanocones: Existence and Stability¹

, KAPIL ADHIKARI, ASOK RAY, Department of Physics, University of Texas at Arlington — A systematic study of silicon carbide nanocones of different disclination angles and different tip geometries using the finite cluster approximation is presented. The geometries of the nanocones have been spin optimized using the hybrid functional B3LYP (Becke's three-parameter exchange functional and the Lee-Yang-Parr correlation functional) and the all electron 3-21G* basis set. The study indicates that the binding energy per atom or the cohesive energy of the nanocones depends not only on the size of the nanocones but also on the disclination angle of the nanocones. The electronic properties of nanocones depend on disclination angles, size of the nanocone clusters and the edge structure of the nanocones. Given similar cluster size, silicon carbide appears to favor tubular structures over two dimensional graphene-like structures. For relatively smaller clusters the B.E./atom oscillates in all cases except in nanocones of disclination angle 300°. This indicates the greater stability of nanocones of some particular size as compared with its neighboring sizes. A study of binding energies, NBO charge, density of states and HOMO-LUMO gaps has been performed for all nanocones from disclination angles of 60° to 300°.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q8 DMP GMAG: Focus Session: Spin Liquids II 208

11:15AM Q8.00001 Absence of magnetic order and unusual spin dynamics in the spin liquid candidate Na₄Ir₃O₈

, PETER BAKER, FRANCIS PRATT, ISIS Facility, STFC Rutherford Appleton Laboratory, DHARMALINGHAM PRABHAKARAN, ANDREW STEELE, TOM LANCASTER, BILL HAYES, STEPHEN BLUNDELL, Oxford University Department of Physics — Na₄Ir₃O₈ has spin-1/2 iridium ions on a hyperkagome lattice of corner sharing triangles and is a candidate three-dimensional spin liquid [1], which has led to active theoretical study [2,3,4]. Previously reported measurements have shown no evidence for magnetic ordering down to temperatures around three orders of magnitude below the Curie-Weiss constant of ~ 650K [1]. We have carried out muon-spin relaxation measurements which exclude magnetic ordering above 55mK. The field dependence of the muon spin relaxation rate provides further information on the spin dynamics with a temperature-dependent crossover between power laws at intermediate fields suggesting that more than one energy scale is relevant to the fluctuations in this system. [1] Y. Okamoto *et al.*, Phys. Rev. Lett. **99**, 137207 (2007). [2] M. J. Lawler *et al.*, Phys. Rev. Lett. **100**, 227201 (2008). [3] Yi Zhou *et al.*, Phys. Rev. Lett. **101**, 197201 (2008). 11:27AM Q8.00002 Short range magnetic correlations and the possible role of frustration in the heavy-fermion CeCu₄Ga

, B.G. UELAND, C.F. MICLEA, K. GOFRYK, Los Alamos National Laboratory, J.S. GARDNER, Indiana University / NIST Center for Neutron Research, F. RONNING, R. MOVSHOVICH, E.D. BAUER, J.D. THOMPSON, Los Alamos National Laboratory — Neutron scattering, longitudinal and transverse resistivity, heat capacity, ac susceptibility, and magnetization measurements on single and polycrystalline samples of the heavy-fermion compound CeCu₄Ga suggest that its hexagonal lattice and disorder due to Ga substitution may frustrate formation of the long-range magnetic order found in its parent CeCu₅. The absence of magnetic Bragg peaks in neutron diffraction data, field-dependent specific heat data, a Weiss temperature of ~ 10 K, and diffuse scattering below ~1 K which can be fit to an isotropic model describing spin-spin correlations between third through fifth nearest neighbors support this suggestion. Kondo behavior also plays a role in determining the physical properties of CeCu₄Ga.

11:39AM Q8.00003 Mean field phase diagram of the layered perovskite (Li, Na)₂IrO₃ in the strong interaction limit: possible realization of spin liquid phases¹

, MEHDI KARGARIAN, JUN WEN, GREGORY A. FIETE, The University of Texas at Austin — We study the phase diagram of layered perovskite (Li, Na)₂IrO₃ with an underlying honeycomb lattice structure in the strongly interacting limit. Because of the strong spin-orbit coupling of iridium, the effective spin exchange model is highly anisotropic and frustrated. We use the Schwinger fermion approach to map out the phase diagram of the model. At the mean field level several spin liquid phases are found: a gapless spin liquid, a chiral spin liquid, and a helical spin liquid phase. Moreover, in the strong exchange coupling limit we obtain a dimerized phase. The gapless spin liquid phase is characterized by Dirac nodes. In the chiral phase the Dirac nodes are gapped in the bulk, and the system possess a nonzero Chern number signifying existence of chiral modes along the boundary of the system. The helical phase preserves time reversal symmetry, has a bulk gap, and features helical gapless edge modes along boundary analogous to those in topological insulators with a nontrivial invariant. We further investigate the nature of the spin liquid phase by considering the gauge fluctuations above the mean field solution. The chiral spin liquid phase is stable as it breaks time reversal symmetry and acquires a nonzero Chern-Simons term in the effective low energy theory.

11:51AM Q8.00004 Magnetic torque measurement in a gapless spin-liquid state of EtMe₃Sb[Pd(dmit)₂]₂

, DAIKI WATANABE, YOSHINORI SENSU, MINORU YAMASHITA, SHO TONEGAWA, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, YUGO OSHIMA, REIZO KATO, Riken, TAICHI TERASHIMA, SHINYA UJI, NIMS, ILYA SHEIKIN, LNCMI — The organic Mott insulator EtMe₃Sb[Pd(dmit)₂]₂ with nearly identical 2D triangular lattice of $S = 1/2$ is the most promising candidate material of a quantum spin liquid, in which gapless spin excitations have been reported by the thermal transport measurements [1]. However, it remains unsettled whether the observed gapless excitations are magnetic ($S \geq 1/2$) or nonmagnetic ($S = 0$). The magnetic torque measurement is a powerful tool to probe the magnetic properties down to very low temperature, because it is not affected by isotropic impurities. We report the magnetic torque measurements of EtMe₃Sb[Pd(dmit)₂]₂ down to 30 mK up to 32 T. A finite magnetic susceptibility is observed at the lowest temperature. Magnetization increases linearly with the magnetic field up to 32 T without exhibiting any anomaly. These results indicate that the gapless excitations reported by the thermal conductivity measurements are magnetic and that the present system is in an algebraic spin liquid phase.

12:03PM Q8.00005 Field-Dependent Instability of the Candidate Quantum Spin Liquid in $\text{EtMe}_3\text{Sb}[\text{Pd}(\text{dmit})_2]_2$ as Revealed by NMR, GEORGIOS KOUTROULAKIS, Los Alamos National Laboratory, TONG ZHOU, STUART E. BROWN, UCLA, JOE D. THOMPSON, Los Alamos National Laboratory, REIZO KATO, RIKEN — In recent years, the two-dimensional spin-1/2 triangular lattice of the organic salt $\text{EtMe}_3\text{Sb}[\text{Pd}(\text{dmit})_2]_2$ has emerged as a candidate for the realization of a quantum spin liquid. Furthermore, thermal conductivity and nuclear magnetic resonance (NMR) experiments unveiled the presence of a low-temperature instability in the spin liquid state, the opening of a spin gap. We performed a detailed ^{13}C NMR study on this material at low temperatures ($30\text{mK} \leq T \leq 1.5\text{ K}$) and for a wide range of external magnetic field values ($B_0 = 0.6 - 9\text{ T}$). In finite fields, a clear break in the temperature derivative of the spin-lattice relaxation is observed at a temperature $T_m(B_0)$, with T_m following the empirical form $T_m(B_0) \sim |B_0 - B_c|^{1/2}$. Moreover, a uniform broadening of the NMR line for finite fields suggests the presence of a small field-induced staggered magnetization. We discuss these results in the context of possible instabilities, and existing thermodynamic data.

12:15PM Q8.00006 Low temperature magnetodielectric coupling in the spin-liquid candidate $\kappa\text{-(BEDT-TTF)}_2\text{Cu}_2(\text{CN})_3$, MARIO POIRIER, SAMUEL PARENT, ALEX COTE, Universite de Sherbrooke, KAZUYA MIYAGAWA, Tokyo University, YASUHIRO SHIMIZU, Nagoya University, KAZUSHI KANODA, Tokyo University — In the context of geometrical frustration of exchange coupling between spins on dimer orbitals, the possibility of a quantum spin-liquid state has been inferred for the quasi-2D organic Mott insulator $\kappa\text{-(BEDT-TTF)}_2\text{Cu}_2(\text{CN})_3$. However, because the geometrical frustration effect is not strong, it has been proposed that the suppression of magnetic order could result from fluctuating quantum electric dipoles. Indeed, non-trivial charge degrees of freedom survive in this dimer Mott insulator as observed in dielectric measurements. Here, we report in-plane microwave dielectric measurements that reveal a coupling of the electric dipoles to the spins at low temperatures. Anomalies in the complex dielectric permittivity are observed at 6 K and around 3–4 K. The one at 6 K is in clear correlation with the thermal expansion measurements for which a second-order phase transition was inferred. The second dielectric anomaly is frequency dependent and cannot be associated to a phase transition; however, it is rapidly modified and ultimately suppressed by a magnetic field which effects are highly anisotropic. These results could be consistent with the scenario of a dipolar-spin liquid phase where spins couple to the dipoles through the interdimer charge fluctuation. Such a phase appears inhomogeneous since the dielectric anomalies are sensitive to thermal cycling and small pressures.

12:27PM Q8.00007 Coulombic Quantum Liquids in Spin-1/2 Pyrochlores, LUCILE SAVARY, University of California, Santa Barbara, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara — We develop a non-perturbative “gauge Mean Field Theory” (gMFT) method to study a general effective spin-1/2 model for magnetism in rare earth pyrochlores. gMFT is based on a novel exact slave-particle formulation, and matches both the perturbative regime near the classical spin ice limit and the semiclassical approximation far from it. We show that the full phase diagram contains two exotic phases: a quantum spin liquid and a coulombic ferromagnet, both of which support deconfined spinon excitations and emergent quantum electrodynamics. Phenomenological properties of these phases are discussed.

12:39PM Q8.00008 Spin Liquid Ground State of Spin-1/2 Square $J_1\text{-}J_2$ Heisenberg Model, HONG-CHEN JIANG, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106, HONG YAO, Department of Physics, Stanford University, Stanford, CA 94305, LEON BALENTS, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CA 93106 — We perform highly accurate density matrix renormalization group (DMRG) simulations to investigate the ground state properties of the spin-1/2 antiferromagnetic (AFM) square lattice Heisenberg $J_1\text{-}J_2$ model on numerous long cylinders with circumference up to 10 lattice spacings. Besides finding the conventional Neel AFM phase at small $J_2/J_1 < 0.41$ and the stripe AFM phase at large $J_2/J_1 > 0.62$, we establish an intriguing gapped quantum spin liquid phase within the parameter space $0.41 < J_2/J_1 < 0.62$ by showing the absence of various conventional broken symmetries as well as by identifying topological features such as finite topological entanglement entropy and topological “even-odd” effect.

12:51PM Q8.00009 Projected wave function study of Z_2 spin liquids on the kagome lattice for the spin-1/2 quantum Heisenberg antiferromagnet, FEDERICO BECCA, CNR Istituto Officina dei Materiali and SISSA, YASIR IQBAL, DIDIER POILBLANC, Laboratoire de Physique Theorique UMR-5152, CNRS and Universite' de Toulouse — Within the class of Gutzwiller projected fermionic wave functions, by using quantum variational Monte Carlo simulations, we investigated the energetics of all possible Z_2 spin liquids that can potentially occur as ground states of the nearest-neighbor $S=1/2$ quantum Heisenberg model on the Kagome lattice [1]. We conclusively show that all gapped and gapless Z_2 spin liquids are higher in energy compared to the $U(1)$ gapless states in whose neighborhoods they lie. In particular, the most promising gapped Z_2 spin liquid (the so-called $Z_2[0, \pi|\beta]$ state), conjectured to describe the ground state [2], is always higher in energy compared to the $U(1)$ Dirac spin liquid. We also extended the $U(1)$ Dirac state and the uniform RVB spin liquid to include next-nearest-neighbor hopping terms, and studied its local and global stability towards various valence bond crystal patterns. We found that a non-trivial 36-site VBC is stabilized upon addition of a small ferromagnetic exchange coupling [3].

1:03PM Q8.00010 Edge states of $(2+1)D$ BF theory as the effective field theory of translational invariant Z_2 spin liquids¹, GIL YOUNG CHO, JOEL MOORE, Physics Department, University of California, Berkeley — We classify $(2+1)$ -dimensional BF field theory as the effective field theory for the achiral and translation invariant Z_2 spin liquids on the square lattice. We use the pattern of the crystal momenta of BF field theory to find the corresponding Z_2 spin liquid. Then, we show that some classes of Z_2 spin liquids can support gapless helical edge states depending on the projective symmetry group of the effective BF theory. We supplement this effective theory by studying possible projective symmetry group of Z_2 spin liquids.

¹Funding support for this work was provided by FENA (G.Y.C) and NSF DMR-0804413 (J.E.M.).

1:15PM Q8.00011 ESR lineshape for a two-dimensional spin liquid state with spinon Fermi surface¹, OLEG STARYKH, RACHEL GLENN, MIKHAIL RAIKH, University of Utah — We propose that ESR experiment can be an informative probe of a putative spin-liquid ground state with a spinon Fermi surface. Our proposal is based on the assumption that in addition to strong and frustrated Heisenberg exchange interactions, the spins also interact via an asymmetric Dzyaloshinskii-Moriya interaction (DMI). We argue that in a spin-liquid state the DMI plays the role of a spin-orbit interaction well-known in low-dimensional conductors. Assuming further spin-orbit interaction to be of Rashba type, we calculate the ESR absorption spectrum of a two-dimensional fermion gas subject to Zeeman and spin-orbit fields. Finite spin-orbit coupling translates into a finite absorption spectrum width. Remarkably, the ESR signal diverges as an inverse square-root at the edges of the spectrum.

1:27PM Q8.00012 Loop condensation in quantum dimer models , C.M. HERDMAN, K.B. WHALEY, UC Berkeley

— The formation of topological order is well understood in terms of the mechanism of loop condensation in systems with loop-like degrees of freedom. Various quantum dimer models possess exotic liquid states, including topologically ordered phases. Dimer models can be mapped to loop models and these dimer liquid phases may be described as loop condensates. We present a numerical study of the geometric properties of the loop condensates in quantum dimer models and related models using classical Monte Carlo as well as ground state quantum Monte Carlo calculations.

1:39PM Q8.00013 Gapless fractionalized vortex liquids in frustrated quantum antiferromagnets , CHONG WANG, SENTHIL TODADRI, MIT

— The standard theoretical approach to gapless spin liquid phases of two-dimensional frustrated quantum antiferromagnets invokes the concept of fermionic slave particles into which the spin fractionalizes. As an alternate we explore new kinds of gapless spin liquid phases in frustrated quantum magnets with XY anisotropy where the vortex of the spin fractionalizes into gapless itinerant fermions. The resulting gapless fractionalized vortex liquid phases are studied within a slave particle framework that is dual to the usual one. We demonstrate the stability of some such phases and describe their properties.

1:51PM Q8.00014 Properties of the short ranged RVB wavefunction on non-bipartite lattices via Pfaffian Monte Carlo¹ , JULIA WILDEBOER, ALEXANDER SEIDEL, Washington University in Saint Louis

— We introduce a Monte Carlo scheme to investigate the nearest neighbor version of Anderson's resonating-valence-bond (RVB) spin-1/2 wave function on the kagome and on the triangular lattice. For the kagome lattice there exists a parent Hamiltonian for this state, but even in the absence of a known Hamiltonian, wave functions of RVB type are interesting as such. The corresponding RVB wave function on the square lattice has recently enjoyed much attention, and it was shown that earlier findings about the criticality of the *dimer*-liquid wave function on the square lattice qualitatively carry over to the analogous *spin*-liquid wave function on this lattice. On bipartite lattices, the spin-1/2 RVB wave functions are amenable to MC methods based on a loop gas picture. For other lattices, this method has a sign problem. We present a method that is free of this sign problem, making use of a Pfaffian presentation of the wave function in the orthogonal Ising basis. Our results for both open and periodic boundary conditions show that spin-spin and "dimer-dimer" type correlation function are exponentially decaying. Time and/or results permitting, we also comment on the behavior of the monomer correlations, and mention possible applications of our method to other problems.

2:03PM Q8.00015 Exact Chiral Spin Liquid on the Ruby Lattice and Mean-Field Perturbations of Gamma Matrix Models¹ , SETH WHITSITT, VICTOR CHUA, GREGORY A. FIETE, Department of Physics, University of Texas at Austin

— We report recent results on the study of an exactly solvable spin-3/2 model of the Kitaev type [A. Kitaev, Ann. Phys. 321, 2 (2006)] and related mean-field studies. The model is a Yao-Zhang-Kivelson Gamma Matrix (GM) extension [H. Yao, S.C. Zhang, and S.A. Kivelson, Phys. Rev. Lett. 102, 217202 (2009)] on the ruby or rhombihexadeltile lattice. We show that the model admits an exact chiral spin liquid ground state solution with emergent free spinon excitations and interesting bandstructure. Specifically, we find gapped phases with chiral edge modes resulting from topologically non-trivial Chern numbers and gapless phases with interesting spinon Fermi surfaces. We have also studied the addition of perturbations to this and other GM Kitaev systems (kagome, square) which leads to weakly interacting spinons. We have applied a mean-field analysis to explore the interplay between these interactions and the gapless spin liquid phases.

Session Q9 DMP GMAG: Focus Session: Complex Bulk Oxide: Doped and Undoped Manganites 209

11:15AM Q9.00001 Weak ferromagnetism in lightly electron-doped CaMnO_3 , HIROMASA OHNISHI,

TAICHI KOSUGI, SHOJI ISHIBASHI, Nanosystem Research Institute (NRI), National Institute of Advanced Industrial Science and Technology (AIST), KIY-OYUKI TERAOKA, Research Center for Integrated Science (RCIS), Japan Advanced Institute of Science and Technology (JAIST) — The origin of the weak ferromagnetism, that is observed in lightly electron-doped CaMnO_3 , is studied by means of the non-collinear spin density functional theory, including the spin-orbit interaction. We show that the spin-canting in the G-type antiferromagnetic structure is realized by the electron-doping, and the canting angle becomes larger with increase of the doping amount. The estimated canting angle is in a good agreement with the experimental value of the Ce-doped CaMnO_3 [1] The spin-canted state is stabilized by the double-exchange interaction, and the spin-orbit interaction does not play a crucial role in this phenomenon. In addition, the spin-canted state shows metallic behavior by the double-exchange transfer that gives a reasonable interpretation for the experimental electronic transport property [2] We also clarify a possibility of the antiferromagnetic-ferromagnetic phase separation [3] that will be realized when doped-electrons are strongly localized.

11:27AM Q9.00002 Synthesis, Structural and Magnetic Characterization of Rare Earth Doped SrMnO_3 Compounds , M.A. JUAREZ-ROSETE, E. CHAVIRA, J.I. BETANCOURT, Instituto de Investigaciones en Materiales, UNAM, Mexico

DF 04510, E.E. MARINERO, Hitachi San Jose Research Center, 3403 Yerba Buena Road, San Jose, CA 95135, L. BUCIO, X. BOKHIMI, Instituto de Fisica, UNAM, Mexico DF 04510 — We report on our ongoing work on the synthesis, characterization and magnetic studies of Rare Earth (RE) containing RE- SrMnO_3 compounds. The aim of the study is to determine how different RE elements influence the magnetic properties of said materials. We have so far investigated the incorporation of Dy and Yb into the SrMnO_3 unit cell. To this effect we have employed solid state reaction synthesis methods to fabricate said compounds. The reaction products evolution were monitored as a function of time by XRD, TGA and SEM. Measurements of lattice parameters and Rietveld refinement of the XRD spectra, indicate that Dy and Yb are incorporated substitutionally in SrMnO_3 . Temperature dependent magnetic measurements, on the other hand, reveal a common transition temperature around 41 K for both Dy and Yb doped SrMnO_3 . We are in the process of synthesizing additional materials containing additional RE elements to investigate how the electronic properties of said RE may influence the magnetic properties of these compounds.

11:39AM Q9.00003 Far-IR spectra of magnons, crystal field transitions, and phonons in hexagonal $RE\text{MnO}_3$ ($RE=\text{Er, Tm, Yb, Lu}$) single crystals¹, E.C. STANDARD, T.N. STANISLAVCHUK, R. BASISTYY, A.A. SIRENKO, Dept of Phys, NJIT, Newark NJ, USA, T.D. KANG, ReCFI, Dept of Phys and Astronomy, Seoul National U., Seoul, Korea, N. LEE, S-W. CHEONG, Rutgers Center for Emergent Materials and Dept of Phys and Astronomy, Rutgers U., NJ, USA — Far-IR spectra of hexagonal $RE\text{MnO}_3$ ($RE=\text{Er, Tm, Yb, Lu}$) single crystals have been studied between $T=1.6$ K and 300 K using transmission in high magnetic field and rotating analyzer ellipsometry. The symmetry of the IR optical phonons and their oscillator strengths were determined for compounds with different RE ions. The temperature dependence of the phonon frequencies revealed a strong spin-phonon interaction in the temperature range below $T_N \sim 70$ K. The effective g-factors have been determined for the AFM resonances and crystal field transitions using external magnetic fields up to 10 T. The frequency of the AFM resonances around 50 cm^{-1} increases systematically with a decrease of the RE ion radius. The observed effects are analyzed taking into account main magnetic interactions in the system including exchange of the Mn^{3+} spins with RE^{3+} paramagnetic moments. The magnetic ordering of RE ions was observed at low temperatures $T < 3.5$ K and in strong magnetic fields.

11:51AM Q9.00004 Direct observation of collective magnetism at ferroelectric domain walls in multiferroic ErMnO_3 , YANAN GENG, NARA LEE, YOUNGJAI CHOI, SANG-WOOK CHEONG, WEIDA WU, Rutgers Center for Emergent Materials & Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, 08854 — Multiferroic hexagonal manganites $RE\text{MnO}_3$ ($RE = \text{Ho, Er, Lu, etc.}$) have been of great interest because of the coexistence of ferroelectric and magnetic orders. Herein we report cryogenic magnetic force microscopy (MFM) studies of flux-grown ErMnO_3 single crystals with vortex ferroelectric domain pattern. By uniquely correlating ambient piezo-response force microscopy and low temperature MFM images at the same location, we identified alternating uncompensated magnetic moments at ferroelectric domain walls that correlate over entire vortex network, suggesting collective magnetism at ferroelectric vortex domain walls.

12:03PM Q9.00005 Maximally localized Wannier functions in LaMnO_3 within PBE+ U , hybrid functionals, and GW: an efficient route to construct ab-initio tight-binding parameters for e_g perovskites, ROMAN KOVACIK, School of Physics, Trinity College Dublin, Dublin 2, Ireland, CESARE FRANCHINI, MARTIJN MARSMAN, Faculty of Physics, University of Vienna and Center for Computational Materials Science, A-1090 Wien, Austria, CLAUDE EDERER, School of Physics, Trinity College Dublin, Dublin 2, Ireland — Using the newly developed VASP2WANNIER90 interface we have constructed maximally localized Wannier functions [1] (MLWFs) for the e_g states of the prototypical Jahn-Teller magnetic perovskite LaMnO_3 at different levels of approximation for the exchange-correlation kernel. These include conventional density functional theory (DFT) with and without additional on-site Hubbard U term, hybrid-DFT, and single shot GW. By suitably mapping the MLWFs onto an effective e_g tight-binding (TB) Hamiltonian [2,3] we have computed a complete set of TB parameters providing the band dispersion in excellent agreement with the underlying *ab initio* and MLWF bands. The method-dependent changes of the TB parameters and their interplay with the electron-electron interaction term are discussed and interpreted, outlining a guidance for more elaborate treatments of correlation effects in effective Hamiltonian-based approaches.

12:15PM Q9.00006 Reverse Monte Carlo Modeling of Pair Distribution Function Data as a Tool for Separating the Coordination Environments of Multiple Atoms Disordered Over a Single Site, GRAHAM KING, ANNA LLOBET, Lujan Neutron Scattering Center, Los Alamos National Laboratory, REBECCA RICCIARDO, JENNIFER SOLIZ, PATRICK WOODWARD, Department of Chemistry, Ohio State University, FARSHID RAMEZANIPOUR, JOHN GREEDAN, Department of Chemistry, McMaster University — The local structures of 8 perovskite compounds which contain equal concentrations of 2 transition metal cations disordered over the B -sites have been investigated using reverse Monte Carlo (RMC) modeling of neutron pair distribution function (PDF) data. Such compounds are known to display a number of interesting magnetic and electronic properties which, due to the cation disorder, cannot be correlated with the average long range structure and so remain poorly understood. In compounds with $B=\text{Mn/Ru}$ there exists a valence degeneracy between $\text{Mn}^{3+}/\text{Ru}^{5+}$ and $\text{Mn}^{4+}/\text{Ru}^{4+}$. We demonstrate that the RMC method can be used as an effective tool to separate out the individual coordination environments of these cations and also to monitor the relative concentrations of the different oxidation states. We find that the valency ratio is governed by the size of the A -site cations. In a different series of $\text{Sr}_2\text{FeMnO}_{6-x}$ perovskites we find that locally the structures are quite different from the average cubic structures, with the local coordination environments more closely resembling those of the brownmillerite structure. In all compounds the octahedra containing Mn^{3+} are Jahn-Teller distorted, even if this distortion is not evident in the average structure.

12:27PM Q9.00007 Direct Visualization of Electric-Field-Driven Migration and Decay of Oxygen Vacancy-induced Stripes in $\text{Pr}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ ¹, DONGMIN CHEN, Institute Of Physics, Chinese Academy of Sciences, ZHAOLIANG LIAO, Institute Of Physics, Chinese Academy of Sciences & Department of Physics and Astronomy, Louisiana State University, XUEDONG BAI, PENG GAO, Institute Of Physics, Chinese Academy of Sciences, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University — We report on the microscopic evidence of electric-field driven migration and decay of oxygen vacancy stripes in $\text{Pr}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$ (PCMO30). A local lattice stripe phase associated with oxygen vacancy migrating along the applied electric field was imaged in real time by using *in-situ* imaging with high-resolution transmission electron microscopy (TEM). Such a field-driven dynamic oxygen migration process should be responsible to the transport for the resistance switching effects observed in many metal-oxide-metal structures, thus providing a direct microscopic evidence for the oxygen migration model. A decay of oxygen vacancy stripes with a characteristic decay time has been observed, consistent with measurement of resistance relaxation in the materials.

12:39PM Q9.00008 Ultrafast pump-probe reflectance study of multiferroic $\text{Eu}_{0.75}\text{Y}_{0.25}\text{MnO}_3$, D. TALBAYEV, Tulane University, J. LEE, S.A. TRUGMAN, R.P. PRASANKUMAR, A.J. TAYLOR, Los Alamos National Laboratory, R.D. AVERITT, Boston University, C.L. ZHANG, S.-W. CHEONG, Rutgers University — Time resolved dynamical studies of multiferroic materials help unravel the fundamental interactions between various degrees of freedom. We report an ultrafast pump-probe reflectance study of multiferroic $\text{Eu}_{0.75}\text{Y}_{0.25}\text{MnO}_3$. The material undergoes antiferromagnetic ordering and, upon further cooling, ferroelectric ordering that strongly couples to the material's magnetic state. We measured the pump-probe reflectance in this compound using 400- and 800-nm pump and probe pulses. We found that the amplitude of the photoinduced reflectance increases dramatically with the development of local and long-range spin-spin correlations as the temperature is lowered toward the magnetic ordering transition. We also observe a dramatic increase in the rise time, up to 10s of picoseconds, of the photoinduced reflectance. This time scale is consistent with the long response times of the spin system in manganites. We suggest that the modification of the local exchange coupling around the photoinduced electrons and holes is responsible for the observed reflectance behavior, as the optical properties of manganites are known to couple strongly to the local and long-range spin correlations [1].

12:51PM Q9.00009 Multiple Magnetic Transitions and Magnetocaloric Effect in (La,Pr,M)MnO₃ (M = Ca, Sr, Ba) Mixed Phase Manganites¹, P.J. LAMPEN, N.S. BINGHAM, M.H. PHAN, H.S. SRIKANTH, University of South Florida, T.L. PHAN, S.C. YU, Chungbuk National University, S.W. CHEONG, Rutgers University — The manganite compound (La,Pr,Ca)MnO₃ is a well-studied system that is known to exhibit a complex phase diagram featuring “strain liquid” and “strain glass” regions in combination with competing ferromagnetic (FM) and charge-ordered antiferromagnetic (CO/AFM) phases. The balance of these phases is sensitive to various perturbations including magnetic and electric field, strain, bandwidth, and A-site cation disorder. The A-site disorder and bandwidth of this compound can be tuned through the replacement of Ca with larger Sr and Ba ions. We report here a systematic study of the influence of cation substitution on the magnetic and magnetocaloric properties of La_{0.35}Pr_{0.275}Mn_{0.375}O₃ (M = Ca, Sr, Ba). Structural properties, including lattice parameters and Mn–O–Mn bond angles, were determined from X-ray diffraction patterns. DC magnetometry studies reveal multiple magnetic transitions in each sample which are probed by magnetocaloric effect (MCE) and transverse susceptibility (TS) experiments. Increasing the average A-site cationic radius is found to strongly impact the magnetic properties and phase behavior of the system.

¹Support provided by DOE-BES Grant No. DEFG02-07ER46438 and FCASST

1:03PM Q9.00010 Evolution of antiferromagnetic order during the colossal magnetoresistive transition, M.A. HOSSAIN, MARK H. BURKHARDT, SLAC, Stanford University, E. WESCHKE, E. SCHIERLE, Helmholtz-Zentrum Berlin, Y. TOMIOKA, National Institute of Advanced Industrial Science and Technology (AIST), Japan, Y. TOKURA, University of Tokyo, J. STÖHR, H.A. DÜRR, SLAC, Stanford University — Pr_{0.7}Ca_{0.3}MnO₃ (PCMO) displays one of the largest colossal magneto-resistances (CMR) among manganites. Magneto-transport data suggest that an insulating antiferromagnetic to metallic ferromagnetic transition occurs as the system goes through a CMR transition with the application of a high magnetic field (3–6T). However, the nature of this transition is a mystery. We report the first high magnetic field resonant soft x-ray scattering (RSXS) experiments on PCMO which follow the evolution of the antiferromagnetic superlattice order through the CMR transition. We find that the antiferromagnetic order is first enhanced by several orders of magnitude before melting away into the metallic ferromagnetic phase. Additional high field x-ray magnetic circular dichroism (XMCD) measurements allow us to track the spin and orbital moments and construct a microscopic picture of the competing forces at the heart of CMR.

1:15PM Q9.00011 Low energy magnetic excitations in phase-separated La_{5/8} – yPryCa_{3/8}MnO₃, JAIME FERNANDEZ-BACA, FENG YE, SONGXUE CHI, WEI TIAN, ORNL, S-W CHEONG, Rutgers University — La_{5/8} – yPryCa_{3/8}MnO₃ (LPCMO) ($y = 0.4$) is one of the prototype materials for the study of phase separation. The end members of the series, La_{5/8}Ca_{3/8}MnO₃ and Pr_{5/8}Ca_{3/8}MnO₃, have a robust low temperature FM metallic and charge ordered insulating states, respectively. Various experimental techniques have shown evidence of two-phase coexistence for intermediate Pr contents. However, a clear understanding of some basic macroscopic signature of phase separation is still lacking. The states of the coexistence phases are different when the system goes through different thermodynamic paths with the application of magnetic field. The zero-field-cooled (ZFC) procedure results in a dominant CO-OO state with little FM clusters at low temperature. Such insulating state is robust against external magnetic field. On the other hand, a zero-field cooled, field warming (ZFC-FW) procedure causes a sudden increase in FM intensity near the glassy transition temperature (TG ~ 25K). In this talk we will present the results of recent elastic and inelastic neutron scattering experiments on a single crystal specimen of LPCMO, which reveal the nature of the complex phase coexistence at low temperatures.

1:27PM Q9.00012 Anisotropic field-induced melting of orbital ordering phase in Pr_{0.6}Ca_{0.4}MnO₃¹, RUN-WEI LI, HUALI LI, YIWEI LIU, Ningbo Institute of Material Technology and Engineering, CAS, Ningbo 315201, P. R. China, JIANDI ZHANG, Louisiana State University, WEI KU, Brookhaven National Laboratory, QINGFENG ZHAN, Ningbo Institute of Material Technology and Engineering, CAS, Ningbo 315201, P. R. China, ZHAOHUA CHENG, BAO-GEN SHEN, Beijing National Laboratory for Condensed Matter Physics & Institute of Physics, CAS, Beijing — The orbital degree of freedom in correlated electron systems plays an essential role in creating versatile phenomena via its coupling with charge, spin, and lattice. One extraordinary phase in doped oxide compounds is the charge/orbital-ordered (OO) antiferromagnetic (AF) insulating state, which, interestingly, can be melted to an orbital-liquid metallic state by external magnetic field. By measuring the field-dependent transport behavior of Pr_{0.6}Ca_{0.4}MnO₃ single crystal at different temperatures, we have found a field-orientation dependent melting of the charge-orbital ordered state, regardless whether or not the system is in AF phase. The field-induced melting is found stronger when the applied field is in the ab (basal)-plane. This can be understood as suppression of the CE-type OO state via spin-orbit coupling induced preference of in-plane orbital direction.

1:39PM Q9.00013 Paramagnetic Spin Correlations in Colossal Magnetoresistive La_{0.7}Ca_{0.3}MnO₃, JEFFREY LYNN, JOEL HELTON, NCRN, National Institute of Standards and Technology, MATTHEW STONE, Oak Ridge National Laboratory, DMITRY SHULYATEV, YAKOV MUKOVSKII, Moscow State Steel and Alloys Institute — Inelastic neutron scattering measurements, taken on the ARCS time-of-flight spectrometer, reveal dynamic spin correlations throughout the Brillouin zone in the colossal magnetoresistive system La_{0.7}Ca_{0.3}MnO₃ at 265 K ($\approx 1.03 T_C$). Well defined correlations are observed in constant- E scans. The long-wavelength behavior can be attributed to spin diffusion, qualitatively consistent with dynamical scaling theory, with a correlation length of ≈ 10 Å. Dynamic correlations are observed at energies up to at least 28 meV, suggesting persistent short range spin correlations in the paramagnetic phase. An additional and unexpected component of the scattering is observed at lower energies which takes the form of ridges of strong scattering running along (H 0 0) and equivalent directions.

1:51PM Q9.00014 Existence of a New Phase in the Intermediate J_{AF} -coupling Regime of the Two-Orbital Model for Manganites¹, CENGIZ SEN, SHUHUA LIANG, ELBIO DAGOTTO, University of Tennessee, Knoxville, TN, and Oak Ridge National Lab, Oak Ridge, TN — We report the existence of a new exotic state in the two-orbital model for manganites in the intermediate J_{AF} coupling regime, analyzed using the standard Monte Carlo technique based on the exact diagonalization of the electronic sector. At density $x = 1/4$, this state shows diagonal ferromagnetic (FM) chains with uniform charge order (CO), stacked in between CE-like zig-zag patterns of spin with less populated staggered CO. The new state exists in a narrow range between the well-known FM metallic and C_xE_{1-x} insulating states, and provide a realization in the clean limit of the nanoscale phase separation scenario of CMR manganites. The existence of many other competing exotic states in this range of couplings will also be discussed.

Session Q10 DCMP DCOMP: Invited Session: Rare Fluctuation Effects in Strongly Disordered Systems 210A

11:15AM Q10.00001 Rare Fluctuation Effects in the Anderson Model of Localization¹, RAVINDRA BHATT, Department of Electrical Engineering and Princeton Center for Theoretical Science, Princeton University, Princeton, NJ 08544 — Two significant advances in the theory of disordered systems in the past three decades have been (i) the development of large disorder Renormalization Group methods, and (ii) a more concerted effort to study of the effects of rare fluctuations or configurations, such as Griffiths' phenomena. A major problem facing the latter in many-body systems has been the enormous numerical resources needed to see these rare phenomena. In this talk, we examine the issue of rare configuration effects in Anderson's original model of localization (1958). In this talk, we examine the issue of rare configuration effects in Anderson's original model of localization. We show that effects due to resonant tunneling among neighboring sites leads not only to anomalous behavior of electronic eigenstates far in the Lifshitz tail, where the density of states is exponentially suppressed, but also leads to singularities in average properties (i.e. the inverse participation ratio) as a function of energy, where the density of states is large. The singular behavior, which separates resonant, Lifshitz-like states from typical, Anderson-localized states, occurs *in the insulating phase*, and thus is present in *all* dimensions [1]. Using the analytic solution of a toy model, as well as numerical results of the Anderson model for several different disorder distributions in dimensions $d = 1, 2$ and 3 , we show that this separation of eigenstates due to rare fluctuations is a ubiquitous property of the Anderson model with *bounded* disorder. This suggests that the half-century-old model, being solvable in polynomial time, is a prime candidate for detailed numerical studies of rare fluctuation effects in disordered systems.

11:51AM Q10.00002 Electronic Griffiths Phases and Quantum Criticality at Disordered Mott Transitions, VLADIMIR DOBROSAVLJEVIC, Director, Condensed Matter Science - Theory, NHMFL Florida State University — The effects of disorder are investigated in strongly correlated electronic systems near the Mott metal-insulator transition. Correlation effects are found¹ to lead to strong disorder screening, a mechanism restricted to low-lying electronic states, very similar to what is observed in underdoped cuprates. These results suggest, however, that this effect is not specific to disordered d-wave superconductors, but is a generic feature of all disordered Mott systems. In addition, the resulting spatial inhomogeneity rapidly increases² as the Mott insulator is approached at fixed disorder strength. This behavior, which can be described as an Electronic Griffiths Phase, displays all the features expected for disorder-dominated Infinite-Randomness Fixed Point scenario of quantum criticality.

12:27PM Q10.00003 Bosons in disordered one-dimensional traps: a new paradigm for the superfluid-insulator transition, GIL REFAEL, California Institute of Technology — No abstract available.

1:03PM Q10.00004 Gaps and Pseudogaps across the inhomogeneous superconductor to paired insulator transition¹, MOHIT RANDERIA, Ohio State University — The mechanism for the disorder-tuned superconductor to insulator transition (SIT) in thin films and the nature of the resulting insulator are still debated, despite decades of research. We use quantum Monte Carlo simulations [1] that treat, on an equal footing, inhomogeneous amplitude variations and phase fluctuations, and go beyond our earlier Bogoliubov-deGennes analysis [2]. We gain new microscopic insights into the SIT, compare our theory with experiments [3] and make testable predictions for local spectroscopic probes. The energy gap in the single-particle density of states survives across the transition, but coherence peaks exist only in the superconducting state. A characteristic pseudogap persists above the critical disorder and critical temperature, in contrast to conventional theories. Surprisingly, the insulator has signatures of pairing with a two-particle gap scale that vanishes at the superconductor-insulator transition, despite a robust single-particle gap. The impact of rare regions on the gaps will also be discussed. In collaboration with K. Bouadim, Y.L.Loh and N. Trivedi.

1:39PM Q10.00005 Infinite-randomness criticality in disordered metals and superconductors¹, THOMAS VOJTA, Missouri University of Science and Technology — Quantum phase transitions in disordered systems often display unconventional behavior which is dominated by rare strongly coupled spatial regions. In this talk, we investigate magnetic and superconducting quantum phase transitions in disordered metallic systems. We develop a strong-disorder renormalization group method that accounts for both quenched disorder and the dissipation of the critical modes due to the Fermi sea. We find that the quantum phase transition in Heisenberg anti-ferromagnets and the pair-breaking superconductor-metal transition are both governed by non-perturbative infinite-randomness critical points. Even stronger disorder effects arise for metallic magnets with Ising spin symmetry in which the quantum phase transition is completely destroyed by smearing. We determine thermodynamic and transport properties at these transitions and in the associated quantum Griffiths phases. We also discuss the current status of experimental observations of these exotic disorder phenomena in a variety of systems including transition metal compounds, heavy-fermion systems, and superconducting nanowires.

Wednesday, February 29, 2012 11:15AM - 1:51PM –
Session Q11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Infrared and Terahertz Spectroscopy 210B

11:15AM Q11.00001 Collective modes in gapped bilayer graphene¹, CHRISTOPHER TRIOLA, ENRICO ROSSI, Department of Physics, College of William and Mary, Williamsburg, VA 23188, USA — We calculate the polarizability of gapped bilayer graphene using the four-band continuum model. In the presence of a gap the four-band model and the simplified two-band model return bands that are qualitatively different especially at low energies. We find that because of these differences the static polarizability obtained using the four-band model is qualitatively different from the one obtained using the two-band model. We also find that the differences between the two-band model and the four-band model profoundly affect the dynamical dielectric function, and therefore the properties of the plasmon modes. In addition, we study the effect of trigonal warping and find that it qualitatively modifies the density response function.

¹Work supported in part by the Jeffress Memorial Trust, Grant No. J-1033

11:27AM Q11.00002 Sum-Frequency Vibrational Spectroscopic Studies of Polymer/Graphene Interface, HUI-LING HAN, Department of Physics, University of California, Berkeley, CHUANSHAN TIAN, Department of Physics, Fudan University, China, FENG WANG, YUEN-RON SHEN, Department of Physics, University of California, Berkeley — The interest in alignment of polymer on graphene surfaces has been motivated by a desire to gain a fundamental understanding the interaction between molecule and graphene, and for possible application of graphene for surface chemistry. Graphene-polymer interactions also play an important role in graphene-polymer composites, which exhibit greatly improved electrical conductivity, strength, and thermal stability compared with pure polymer material. Theoretical investigation of graphene-polymer interface has been performed previously using molecular dynamics simulations [1]. However, experimental studies of the interfacial characteristics of graphene-polymer composite has been challenging. Here we investigate the molecular orientation at polymer/graphene interface using phase-sensitive-sum-frequency generation spectroscopy. The sum-frequency spectrum shows clear vibration signatures of CH₂ groups. In particular, it suggests that CH₂ groups pointing toward the graphene surface interact with graphene strongly, which leads to a red shift of vibration frequency as large as 15 cm⁻¹. In this talk I will discuss the implications of our experimental findings.

11:39AM Q11.00003 Tunable Quantum-Enhanced Second-Order Optical Nonlinearity From Bilayer Graphene, SANFENG WU, Department of Physics, University of Washington, Seattle, 98195, United States, LI MAO, Department of Physics and Astronomy, Washington State University, Pullman, WA, 99164 USA, WANG YAO, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, WA, 99164 USA, XIAODONG XU, Department of Physics and Department of Material Science and Engineering, University of Washington, Seattle, 98195, United States — Bilayer graphene exhibits a tunable band gap when the inversion symmetry is broken. It therefore stimulates much interest on its physical characterization and practical application for mid-infrared (MIR) optoelectronics. Here we focus on its second order nonlinear optical response to the MIR laser excitation under device condition, following a quantum description of nonlinear optical conductivity. Our theoretical study shows that, for a certain laser-frequency range determined by the band-gap, giant second harmonic generation can be excited due to the intrinsic electronic spectrum of bilayer graphene. Electrically tunable $\chi^{(2)}$ on the order of $10^5 pm/V$ can be achieved, 3 orders of magnitude larger than the widely-used nonlinear crystal AgGaSe₂.

11:51AM Q11.00004 Infrared magneto-spectroscopy of graphene-based systems, MILAN ORLITA, Laboratoire National des Champs Magnétiques Intenses, CNRS, Grenoble — The results of infrared magneto-spectroscopy of different graphene-based materials will be presented. These systems involve multi- and mono-layers of epitaxial graphene, decoupled graphene flakes on the surface of graphite as well as bulk graphite. The magneto-optical methods serve us mostly as a tool of Landau level spectroscopy. It is used to study the characteristic response due to massless or massive Dirac-type particles and, e.g., to distinguish materials with graphene layers exhibiting rotational or Bernal stacking. Broadening of inter-Landau level transitions has been traced as a function of magnetic field and energy to evaluate the quality of multi-layer epitaxial graphene in terms of scattering time and carrier mobility. From broadening of overlapping Landau levels we find that the scattering rate increases linearly with energy. Complementary to these experiments, inelastic relaxation processes have been studied in pump-and-probe measurements in THz range. The obtained data indicate that the inelastic processes are significantly slower than the elastic ones, and also that the inelastic relaxation is slowed down when the photon energy is tuned to values below the optical phonon frequency. References: M. Orlita et al., PRL, to be published (2011); S. Winnerl et al., PRL, to be published (2011).

12:27PM Q11.00005 Far-infrared Kerr rotation spectroscopy of graphite and multilayer graphene, JULIEN LEVALLOIS, MICHAËL TRAN, ALEXEY KUZMENKO, University of Geneva — Graphite attracts much attention nowadays as a reference 3D material for graphene. Since the early measurements of the cyclotron effect in graphite over fifty years ago [1], a satisfactory quantitative description of this spectacular phenomenon is missing. The analysis of magneto-optical data was hindered either by a limited set of the used photon energies or by the lack of the optical selectivity between electrons and holes. We overcome this issue by measuring the far-infrared magneto-optical Kerr rotation spectra [2] and achieve a highly accurate unified microscopic description of all spectra in a broad range of magnetic fields (0.5 – 7 T) by taking rigorously the c-axis band dispersion and the trigonal warping into account. We find that the second- and the forth-order cyclotron harmonics are optically almost as strong as the fundamental cyclotron resonance even at high fields. The same effects are expected to strongly influence the magneto-optical spectra of Bernal stacked multilayer graphene and therefore play a major role in the respective applications.

12:39PM Q11.00006 “Intrinsic” terahertz plasmons and magnetoplasmons in single layer graphene on SiC, IRIS CRASSEE, DPMC, Université de Genève, Suisse, MILAN ORLITA, LNCMI, CNRS-UJF-UPS-INSA, Grenoble, France, Charles University, Praha, Czech Republic, MAREK POTEMSKI, LNCMI, CNRS-UJF-UPS-INSA, Grenoble, France, DIRK VAN DER MAREL, DPMC, Université de Genève, Suisse, MARKUS OSTLER, THOMAS SEYLLER, University of Erlangen-Nurnberg, Erlangen, Germany, ALEXEY KUZMENKO, DPMC, Université de Genève, Suisse — Plasmons in graphene have lately attracted much attention, to great extent, due to promises for novel technologies. Recently, plasmon absorption in graphene was attained in deliberately patterned structures [1]. We measured the magneto-optical absorption and Faraday rotation response of highly doped single layer graphene, epitaxially grown on Si-terminated SiC substrate. The zero-field spectra show a clear plasmon peak at about 2 THz. In magnetic fields, the plasmon peak splits into two branches, thus showing a characteristic magneto-plasmon behavior which was previously observed in periodic dot structures in GaAs two dimensional electron gases [2]. Hence, in large-scale epitaxial graphene on SiC, light can couple to plasmons in the absence of the intentional patterning of graphene. We suggest that optically-active plasmon absorption in this kind of two-dimensional system arises from laterally confined plasmon modes due to “intrinsic” imperfections of graphene on Si-face of SiC, such as, grain boundaries which we clearly identify with AFM methods.

12:51PM Q11.00007 Enhanced Optical Dichroism of Graphene Nanoribbons¹, VITOR M. PEREIRA, F. HIPOLITO, Graphene Research Centre and Department of Physics, National University of Singapore, A.J. CHAVES, R.M. RIBEIRO, M.I. VASILEVSKIY, N.M.R. PERES, Department of Physics and Centre of Physics, University of Minho, Portugal. — The optical conductivity of graphene nanoribbons is analytical and exactly derived. It is shown that the absence of translational invariance along the transverse direction allows considerable intra-band absorption in a narrow frequency window that varies with the ribbon width, and lies in the THz band for ribbons 10-100nm wide. In this region the anisotropy in the optical conductivity can be as high as two orders of magnitude, which renders the medium dichroic, and allows near 100% polarizability with just a single layer of graphene. The interplay between the geometrically induced anisotropy with the anisotropy induced by plasmon absorption is also considered and discussed.

1:03PM Q11.00008 Quasiparticle properties in graphene¹, EUYHEON HWANG, CMTc, University of Maryland at College Park — The quasiparticle properties in both single layer and bilayer graphene are presented. We study the electron self-energy as well as the quasiparticle spectral function in graphene, taking into account electron-electron interaction in the leading order dynamically screened Coulomb coupling and electron-impurity interaction associated with quenched disorder. Our calculation of the self-energy provides the basis for calculating all one-electron properties of graphene. We provide analytical and numerical results for quasiparticle renormalization in graphene. Comparison with existing angle-resolved photoemission spectroscopy measurements shows broad qualitative and semiquantitative agreement between theory and experiment, for both the momentum-distribution and energy-distribution curves in the measured spectra. We also present the inelastic quasiparticle scattering rate and the carrier mean free path for energetic hot electrons as a function of carrier energy, density, and temperature, including both electron-electron and electron-phonon interactions. Our results are directly applicable to device structures where ballistic transport is relevant with inelastic scattering dominating over elastic scattering.

1:39PM Q11.00009 Anisotropy of π -plasmon Dispersion Relation of AA-stacked Graphite, C.W. CHIU, Department of Physics, National Cheng Kung University, Tainan 710, Taiwan, F.L. SHYU, Department of Physics, R.O.C. Military Academy, Kaohsiung 830, Taiwan, M.F. LIN, Department of Physics, National Cheng Kung University, Tainan 710, Taiwan, GODFREY GUMBS, OLEKSIY ROSLYAK, Department of Physics and Astronomy, Hunter College at the City University of New York, 695 Park Avenue New York, NY 10065 USA — The dispersion relation of optical π -plasmons of simple hexagonal intrinsic graphite was calculated within the self-consistent-field approximation. The plasmon frequency ω_p is determined as functions of the wave vector $q_{\parallel}$ along the hexagonal plane in the Brillouin zone and its perpendicular component q_z . These plasmons are isotropic within the plane in the long wavelength limit. As the in-plane wave vector is increased, the plasmon frequency strongly depends on its magnitude and direction (ϕ). Our results reveal that interlayer interaction could enhance anisotropy of in-plane π -plasmons. The group velocity for plasmon propagation along the perpendicular direction may be positive or negative depending on the choice of in-plane wave vector.

Session Q12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties
- SiC and Growth Kinetics 210C

11:15AM Q12.00001 From above or from below? Determining how graphene layers form on SiC(0001), JAMES HANNON, IBM Research Division — SiC decomposes when heated above 1200 C in vacuum. Silicon desorbs, while the carbon left behind can coalesce to form graphene. Growth of graphene on the SiC(0001) surface (“Si face”) and the SiC(000-1) (“C face”) is very different. On the Si face, graphene growth is epitaxial, while on the C face the growth is generally much less ordered. On the Si face, the observed epitaxy suggests that new graphene layers form under existing one, that is, at the SiC/graphene interface. The lack of epitaxy on the C face suggests that the growth mode on this surface might be different. To test this, we grew ultra-thin epitaxial SiC films (1 nm) on both SiC(0001) and SiC(000-1) via CVD using isotopically pure carbon-13. We then formed graphene via high-temperature thermal decomposition. We used medium energy ion scattering to determine where the carbon-13 was located within the graphene film. For both the Si face and C-face, we find that the carbon-13 is located predominantly in the outmost graphene layer, confirming that graphene grows “from the inside out” on both surfaces [1]. This work was performed in collaboration with Matt Copel and Ruud Tromp.

[1] Phys. Rev. Lett. 107, 166101 (2011)

11:51AM Q12.00002 STM/STS study of ridges on epitaxial graphene/SiC¹, Y.Y. LI, Y. LIU, M. WEINERT, L. LI, Department of Physics, University of Wisconsin, Milwaukee, WI 53211 — The graphitization of hexagonal SiC surfaces provides a viable alternative for the synthesis of wafer-sized graphene for mass device production. During later stages of growth, ridges are often observed on the graphene layers as a result of bending and buckling to relieve the strain between the graphene and SiC substrate. In this work, we show, by atomic resolution STM/STS, that these ridges are in fact bulged regions of the graphene layer, forming one-dimensional (nanowire) and zero-dimensional (quantum dot) nanostructures. We further show that their structures can be manipulated by the pressure exerted by the STM tip during imaging. These results and their impact on the electronic properties of epitaxial graphene on SiC(0001) will be presented at the meeting.

¹Supported by DOE (DE-FG02-05ER46228)

12:03PM Q12.00003 Scalable templated growth of graphene patterns on SiC and their electronic properties, MING RUAN, JAMES PALMER, JOHN HANKINSON, YIKE HU, BAIQIAN ZHANG, ZELEI GUO, RUI DONG, ANTON SIDOROV, ZHIGANG JIANG, School of Physics, Georgia Institute of Technology, CLAIRE BERGER, CNRS- Institut Néel, Grenoble, France & School of Physics, Georgia Institute of Technology, WALT DE HEER, School of Physics, Georgia Institute of Technology — Conventional graphene growth research focuses on SiC on-axis surfaces: SiC (0001) and (000-1). In our previous work, we showed that graphene can be selectively grown on off-axis SiC crystal facets, demonstrated the possibility for templated graphene growth. Here we show scalable production of various devices made with this technique, such as graphene nanoribbons, Hall bars and Aharonov–Bohm rings. Graphene and SiC crystal facets are characterized with SEM and SPM tools. Shubnikov-de Haas oscillations and other phase coherent transport phenomena are observed at low temperature. These observations indicate that the structured epitaxial graphene growth can be a viable method for graphene electronics.

12:15PM Q12.00004 A study of epitaxial graphene/SiC(0001) functionalized by nitrogen doping¹, S. RAJPUT, Y. LIU, Department of Physics, University of Wisconsin, Milwaukee, WI 53211, H. YU, R. F. HICKS, Department of Chemical and Biomolecular Engineering, University of California, Los Angeles, CA 90095, L. LI, Department of Physics, University of Wisconsin, Milwaukee, WI 53211 — In this work, we have carried out nitridation of epitaxial graphene/SiC(0001) using N₂ plasma. The effects of processing conditions on the structure of graphene have been investigated by x-ray photoemission spectroscopy and Raman spectroscopy, and changes in the electronic structures of the nitrogen-doped graphene have been studied using scanning tunneling microscopy. We find that the exposure of epitaxial graphene to nitrogen plasma not only leads to N incorporation, but also creates carbon vacancies, resulting in the formation of N-vacancy complexes.

¹Supported by DOE (DE-FG02-05ER46228)

12:27PM Q12.00005 Creation and sculpting of graphene with ion and electron beams, CHRISTOPHER RUSSO, Harvard University Department of Physics — This talk will cover our recent work on the creation of graphene by ion implantation of carbon into copper substrates followed by a prescribed annealing procedure. We also discuss nanopore nucleation with ion beams and the direct observation of nanopore growth in an aberration corrected TEM. We discuss the cross-sections and knock-on energy transfers required for edge atom removal and demonstrate the controlled growth of monodisperse nanopores in graphene with atomic precision.

1:03PM Q12.00006 Spatially Selective Graphene Formation on Si Substrate¹, NAILI YUE, YONG ZHANG², RAPHAEL TSU, UNC-Charlotte — A uniform large area graphene is useful for applications such as electrode in a touch screen or substrate for growing another material. For applications where graphene is used either as active material (FET for instance) or electrode in a 2-D device array, to form a 2D (electronic) superlattice or photonic crystal, it is critically important to be able to form graphene at selective locations, in desirable size and shape on a substrate, without relying on mechanical cutting. It would be even more significant if the substrate is a Si wafer for coupling with the mature microelectronic technology. We have developed a technique that can achieve these goals. A thin SiC film is first deposited on a Si substrate using MBE. Then, at ambient condition, a focused laser beam is used to convert SiC to graphene at the selected location with the shape and size that can be defined by either a lithographic method or simply by a focused laser beam. The graphene conversion has been verified by structural characterization (TEM, SEM/EDS, etc.) and Raman spectroscopy.

1:15PM Q12.00007 Surface reconstruction and graphene formation on face-to-face 6H-SiC at 2000 °C, RANDOLPH E. ELMQUIST, MARIANO REAL¹, BRIAN G. BUSH, TIAN SHEN, MARK D. STILES, ERIC A. LASS, National Institute of Standards and Technology — Improved epitaxial graphene films have been widely reported when the sublimation rate of Si is reduced by ambient Ar gas, vapor phase silane, or confined Si vapor. We describe graphene growth on (0001) 6H-SiC samples annealed “face-to-face” [1]; in our modified method the separation is limited only by the flatness of the surfaces. After annealing in 100 kPa Ar gas at 2000 °C for 300 s, atomic force microscopy (AFM) and electrostatic force microscopy (EFM) show graphene coverage is typically between one and a few layers. Samples without prior hydrogen etching undergo surface reconstruction in the graphitization process, resulting in atomically flat terraces with step bunching. Estimates of the sequestered carbon in the form of graphene are compared to calculated levels due to sublimation and diffusion rates where the sublimated gas is dominated by Si atoms below 2100 °C. The 2000 °C samples are contrasted against samples processed between 1700 °C and 1900 °C and transport results on large-scale graphene devices are presented.

1:27PM Q12.00008 Imaging grain boundary scattering of graphene in real space, SHUAI-HUA JI¹, JAMES B. HANNON, RUUD M. TROMP, IBM T. J. Watson Research Center, Yorktown Heights, NY, CHOCKALINGAM SUBBIAH, ABHAY PASUPATHY, TONY F. HEINZ, Department of Physics, Columbia University, NY, FRANCES M. ROSS, IBM T. J. Watson Research Center, Yorktown Heights, NY — Graphene grain boundaries are unavoidable defects in most growth methods, in particular chemical vapor deposition and thermal decomposition on the SiC(0001) surface. How electrons are scattered by those grain boundaries has not been experimentally demonstrated at the nanoscale. Here we report atomic-scale images of grain boundary scattering measured by scanning tunneling potentiometry (STP). Monolayer graphene sheets were synthesized on the SiC(0001) surface by thermal decomposition in a background of disilane, using low energy electron microscopy to monitor the graphene thickness during its formation. High resolution scanning tunneling microscopy (STM) reveals graphene grain boundaries and various grain orientations, and STP shows variations in voltage across grains and terraces as current flows across the graphene layer. We have identified two types of grain boundary. One shows a trench structure in STM images; potential mapping shows prominent potential drops. These boundaries between grains appear to be weak links and the dominant scattering locations. The other type of boundary shows a continuous lattice between the grains, with periodic dislocations accommodating the grain misorientation. Potential mapping indicates much weaker scattering despite the grain misorientation. We will discuss transport in polycrystalline graphene based on these measurements.

1:39PM Q12.00009 Imaging of Electron Beam Induced Current in Epitaxial graphene¹, SHIN MOU, JOHN BOECKL, WEIJIE LU, J.H. PARK, W.C. MITCHEL, Air Force Research Laboratory, STEPHEN TETLAK, Wyle Laboratories — It has been observed that there forms a Schottky junction between graphene and SiC in epitaxial graphene due to the work function difference. As a result, it is viable to apply the electron beam induced current (EBIC) technique on epitaxial graphene due to the fact that it needs a built-in field and ample electron generation volume to generate EBIC. EBIC is an important characterization technique, which identifies electrically active impurities/defects, detects local built-in field, and measures minority carrier diffusion length. In this paper, we use a FEI SEM equipped with a current amplifier to investigate the spatial mapping of EBIC. The incident electron beam generates excited electron-hole pairs in SiC and the minority carriers are collected through the Schottky junction before flowing into graphene. EBIC imaging reveals mesoscopic domains of bright and dark contrast areas due to local EBIC polarity and magnitude, which is believed to be the result of spatial fluctuation in the carrier density in graphene. We also investigate the electron energy dependence, which modulates the EBIC magnitude. With an analytical drift-diffusion current model, we are able to extract the minority carrier diffusion length in the SiC, which is on the order of micro meter.

1:51PM Q12.00010 Writing Graphene Nanoribbons on SiC by Selective Graphitization¹, SEFAAT-TIN TONGAY, MAX LEMAITRE, Department of Material Science and Engineering, University of Florida, JOEL FRIDMANN, Raith USA Inc., Ronkonkoma, New York, ARTHUR F. HEBARD, Department of Physics, University of Florida, BRENT GILA, BILL R. APPLETON, Department of Material Science and Engineering, University of Florida — We describe a new technique for selective graphene growth onto 4H- and 6H-SiC by ion implantation. The presented technique is as easy as patterning (ion implanting) regions where graphene layers are desired followed by annealing to 100 C below the graphitization temperature (T_G) of SiC. We find that ion implantation of SiC lowers the T_G of SiC, allowing selective graphene growth at temperatures below the T_G of pristine SiC and above T_G of implanted SiC. Presented results provide a new technique to pattern device structures ranging from nanometers to microns in size without using conventional lithography and chemical processing.

¹National Science Foundation and Office of Naval Research

2:03PM Q12.00011 Nucleation of uniform mono- and bilayer epitaxial graphene on SiC(000 $\bar{1}$)¹, XIAOSONG WU, RUI ZHANG, Department of Physics, Peking University, YUNLIANG DONG, Department of Physics, Guangxi Normal University, SHUAI GUO, Department of Physics, Peking University, WENJIE KONG, Department of Physics, Guangxi Normal University, ZHIMIN LIAO, DAPENG YU, Department of Physics, Peking University — Early stage of epitaxial graphene growth on SiC(000 $\bar{1}$) has been investigated. Using the confinement controlled sublimation (CCS) method, we have achieved well controlled growth and been able to see the formation of mono- and bilayer graphene islands. The growth features reveal the intriguing growth mechanism. In particular, a new “stepdown” growth mode has been identified. Graphene can propagate tens of micrometers across many SiC steps, while, most importantly, step bunching is avoided and the initial regular stepped SiC surface morphology is preserved. The stepdown growth demonstrates a route towards uniform epitaxial graphene in wafer size without sacrificing the initial substrate surface morphology.

Session Q13 DMP GMAG: Focus Session: Magnetic Nanostructures-Nanoparticle Synthesis and Magnetism 211

11:15AM Q13.00001 Synthesis and properties of magnetic ceramic nanoparticles¹, MONICA SORESCU, Duquesne University — Magnetic ceramic nanoparticles of the type $x\text{In}_2\text{O}_3-(1-x)\alpha\text{-Fe}_2\text{O}_3$, $x\text{V}_2\text{O}_5-(1-x)\alpha\text{-Fe}_2\text{O}_3$ and $x\text{ZnO}-(1-x)\alpha\text{-Fe}_2\text{O}_3$ ($x=0.1-0.7$) were synthesized from the mixed oxides using mechanochemical activation for 0-12 hours. X-ray diffraction was used to derive the phase content, lattice constants and particle size information as function of ball milling time. Mossbauer spectroscopy results correlated with In^{3+} , V^{5+} and Zn^{2+} substitution of Fe^{3+} in the hematite lattice. SEM/EDS measurements revealed that the mechanochemical activation by ball milling produced systems with a wide range of particle size distribution, from nanometer particles to micrometer agglomerates, but with a uniform distribution of the elements. Simultaneous DSC-TGA investigations up to 800 degrees C provided information on the heat flow, weight loss and the enthalpy of transformation in the systems under investigation. This study demonstrates the formation of a nanostructured solid solution for the indium oxide, an iron vanadate (FeVO_4) for the vanadium oxide, and of the zinc ferrite (ZnFe_2O_4) for the zinc oxide. The transformation pathway for each case can be related to the oxidation state of the metallic specie of the oxide used in connection with hematite.

11:27AM Q13.00002 Magnetic Interactions in Binary Nanocrystal Superlattices¹, JING CAI, JUN CHEN, ANGANG DONG, XINGCHEN YE, YIJIN KANG, CHRISTOPHER B. MURRAY, JAMES M. KIKKAWA, University of Pennsylvania — The recent development² of highly ordered three-dimensional assemblies of magnetic nanocrystals (NCs) poses new questions for the study of collective magnetic dipolar interactions. Prior literature has focused on changes in blocking temperature in infinite, random assemblies. Here, we study ordered assemblies with two different magnetic NCs and complex superlattice unit cells. Monte Carlo simulations are compared with data to clarify magnetic behaviors in AB_{13} superlattices consisting of two different-sized (14.3 nm and 7.2 nm) Fe_3O_4 NCs, which are superparamagnetic in isolation. This strategy illuminates the individual sublattice properties and their interaction. We show that under certain circumstances, the magnetic response of smaller magnetic NCs may be quenched by the random magnetic field of larger magnetic NCs,³ and that trends in blocking temperature with interaction strength depend strongly on both unit cell geometry and boundary conditions.

11:39AM Q13.00003 Fabrication of Iron Oxide Nanoparticle Monolayers by Electrophoretic Deposition¹, ALEX KREJCI, ISABEL GONZALO-JUAN, JAMES DICKERSON, Department of Physics and Astronomy, Vanderbilt University — Magnetic nanoparticle (NP) films are potentially useful in a variety of applications, such as magnetic storage media and ultra-strong permanent magnets. Monolayers of magnetic NPs are specifically interesting as the monolayer geometry maximizes film interactions with dissimilar materials below and above the monolayer. However, many potential commercial and industrial applications of NP films rely on fabrication techniques that are facile, rapid, and site-selective which create homogenous, densely packed, defect-free thin films. Electrophoretic deposition (EPD) is a technique for forming thin films that meets all of these criteria. This work shows, for the first time, EPD's utility in forming monolayers of magnetic NPs. Iron oxide NPs (~14nm) have been synthesized using a solution phase synthesis technique. Repeated centrifugation of the particles prepares the NPs for EPD. The particles are then deposited onto silicon substrates with EPD using dc electric fields. Analysis of the films using scanning electron microscopy and atomic force microscopy shows the particles deposit as NP monolayers. The monolayer density and deposition rate are controlled by varying the suspension concentration and the deposition time. Future research will focus on creating long-range order within the monolayers.

11:51AM Q13.00004 Curie temperature reduction in SiO₂-coated ultrafine Fe₃O₄ nanoparticles: Quantitative agreement with a finite-size scaling law, WEI WU, JUN WANG, FAN ZHAO, Ningbo University, GUO-MENG ZHAO, California State University, Los Angeles — We report high-temperature magnetic measurements for SiO₂-coated ultrafine Fe₃O₄ nanoparticles. The Curie temperatures of the ultrafine Fe₃O₄ nanoparticles are significantly reduced and follow a finite-size scaling law predicted from Monte Carlo simulations. Our current result provides the first quantitative confirmation of the finite-size scaling law for quasi-zero-dimensional magnetic systems.

12:03PM Q13.00005 Magnetic properties of Fe nanoparticles: application of the DFT-Inhomogeneous-DMFT approach¹, ALAMGIR KABIR, Department of Physics, University of Central Florida, Orlando, FL 32816, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics and NSTC, University of Central Florida, Orlando, FL 32816 — Dynamical Mean-Field Theory (DMFT) in combination with Density Functional Theory (DFT) has been successfully applied to examine the properties of transition metal elements in which correlation plays an important role. It was recently shown that this approach can also be applied to study correlation effects in nanostructures [1]. Here we present results of a combined DFT-inhomogeneous-DMFT approach used to investigate the size dependent magnetic properties of small iron clusters containing 15 to 19 atoms. For the DMFT impurity solver we use the iterated-perturbation theory approximation. The numerical analysis with the code developed in our group allows one to study systems consisting up to several hundred atoms. The optimized structure of the Fe clusters is obtained from spin polarized DFT calculations. We find our approach to yield better agreement with experimental data [2] than that obtained using DFT and DFT+U, which generally overestimates the magnetization.

12:15PM Q13.00006 Finite-size scaling behavior and intrinsic critical exponents of nickel: Consistent with the three-dimensional Heisenberg model, JUN WANG, WEI WU, FAN ZHAO, Ningbo University, GUO-MENG ZHAO, California State University, Los Angeles — We report high-temperature magnetic measurements of silica-coated nickel nanoparticles. The Curie temperature is found to decrease with decreasing particle size and follow a finite-size scaling relation with the correlation length exponent $\nu = 1.06 \pm 0.07$. The measured exponent is in excellent agreement with the reported values for nickel nanowires and some nickel thin films. By carefully analyzing the reported thickness dependencies of the Curie temperatures for some nickel films, we show that the intrinsic ν value for nickel is 0.73 ± 0.03 while the much larger ν values (about 1.0) found for some other samples might arise from the presence of long-range correlated disorder near the surface. The intrinsic ν value together with the experimental values of other critical exponents consistently shows that the three-dimensional Heisenberg model is sufficient to describe the ferromagnetism of nickel. Our current work thus resolves a long standing controversy in this field.

12:27PM Q13.00007 Self-assembly of Superparamagnetic Nanoparticles with Permanent Magnetization¹, SUVOJIT GHOSH, ISHWAR PURI, Virginia Tech — Magnetic nanoparticles (MNPs) exhibit superparamagnetism when thermal fluctuations overcome the potential barrier for spin reversal set by magnetocrystalline anisotropy. The magnetic moment in such a material oscillates between the easy axes leading to zero net magnetization. Stable colloidal dispersions of MNPs exploit this state to prevent agglomeration. Self-assembly of MNPs presents an excellent bottom up nanofabrication technique due to the wide range of structures that can be formed. A stable dispersion of MNPs is an essential starting point for good control of the process. In this study we explore the theoretical basis for a self-assembled MNP structure with permanent magnetization starting from a dispersion of superparamagnetic MNPs. Magnetostatic coupling of dipole moments enhance the potential barrier for magnetization reversals. We use X-Ray microCT and TEM to visualize the self-assembled structures. We use a stochastic form of the Landau-Lifshitz-Gilbert equation to simulate the magnetization dynamics in each MNP. Permanent magnetization in self-assembled structures generated *in situ* promise several significant applications such as targeted drug delivery, tissue engineering and novel soft composites.

¹The X-Ray microCT scans were supported by NSF Major Research Instrumentation grant (CMMI0923297).

12:39PM Q13.00008 Rate-dependent hysteresis losses in ensembles of magnetic nanoparticle clusters¹, ONDREJ HOVORKA, RICHARD EVANS, The University of York, UK, GARY FRIEDMAN, Drexel University, Philadelphia, USA, ROY CHANTRELL, The University of York, UK, DREXEL UNIVERSITY COLLABORATION — Hysteresis is ubiquitous in magnetic nanoparticle systems and understanding how it emerges from complex interactions and for different time scales is a long-standing issue in magnetism research. Understanding the phenomenon is most important for engineering magnetic nanoparticle structures of well-controlled properties in magnetic recording, hysteresis loss optimization in hyperthermia cancer treatment in biomedicine, or biological and chemical sensing, to name a few examples. In this work we address one of the general questions related to the influence of thermal activation processes on hysteresis loss. Employing large-scale computational modeling based on the master-equation framework we investigate the influence of dipolar interactions on thermal hysteresis loops in ensembles of magnetic nanoparticle chains and clusters. We show that the directional dependence of dipolar interactions results in enhanced or reduced hysteresis loss, depending on the distribution of particles' anisotropy axes and particle chain orientations with respect to the external field. Additional hysteresis loss reduction occurs in case of particle clusters due to possibility of the frustration phenomenon not present for topologically simpler chains.

12:51PM Q13.00009 Size dependence and thermal stability of chiral states in ferromagnetic nanoparticles deposited on a ferromagnetic substrate¹, NAOISE GRISEWOOD, JOHN EVES, HANS-BENJAMIN BRAUN, University College Dublin — Chiral magnetization profiles are observed in many low dimensional systems such as nanoscale particles, thin films, or bulk systems such as multiferroic samples, that are characterized by a lack of inversion symmetry. These spiraling spin structures are often size-dependent and can be attributed to the competition between exchange and anisotropic, or parity breaking Dzyaloshinskii-Moriya (DM) terms. To utilize such spiraling magnetization profiles in novel spintronic devices, it is necessary to understand the mechanisms under which these spiral spin configurations form and how they can be harnessed via an external field. Here we present exact analytic solutions for the magnetization profiles and the associated energies and energy barriers for ferromagnetic nanoparticles deposited on a ferromagnetic substrate. Our method allows us to determine the critical length at which spiral solutions are supported in such samples, which we find to be $l_c = (\pi/2) \sqrt{A/K_e}$ for vanishing applied field and a misfit angle of $\pi/2$ between substrate and nanoparticle anisotropy axis. We also demonstrate that in absence of further pinning effects, the nanoparticles are exclusively in a uniform state for $l < l_c$. We show that our theory is in good agreement with recent experiments.

1:03PM Q13.00010 Magnetic and magnetocaloric properties of NdMnO₃ nanoparticles¹, SAYAN CHANDRA, ANIS BISWAS, M.H. PHAN, H. SRIKANTH, University of South Florida, FUNCTIONAL MATERIALS LABORATORY TEAM — Recently nanosized manganites have attracted considerable attention as the reduction of particle size has exotic effect on their properties. We have studied the magnetic properties and magnetocaloric effect (MCE) of NdMnO₃ nanoparticles with particle size ~20 and 30nm (denoted as S20 and 30 respectively). In temperature dependence of magnetization, M(T), a paramagnetic to ferromagnetic transition is observed at $T_C \sim 70\text{K}$ for S20, which is 5K higher than that for S30 indicating enhancement of ferromagnetic interaction with particle size reduction. In addition to this, an anomaly in M(T) is observed at 20K (T_{CA}) for both S20 and S30, which is attributed to the stabilization of a canted magnetic state (CMS) due to the ordering of Nd^{3+} . The magnetic entropy change [$-\Delta S_M(T)$] is calculated from isothermal magnetization curves using Maxwell relation. There are two maximas in $-\Delta S_M(T)$ at T_C and T_{CA} indicating large MCE over both temperature regions. Interestingly, the relative cooling power is enhanced in case of smaller particle size in which the influence of stabilization of CMS on MCE is less pronounced.

¹DOE-BES Grant No. DEFG02-07ER46438 and FCASST

1:15PM Q13.00011 Effect of the size distributions of magnetic nanoparticles on metastability using phonon-assisted transition rates, YOH YAMAMOTO, KYUNGWHA PARK, Virginia Tech — Experiments show that magnetic nanoparticles have distributions of sizes and shapes, and that the distributions greatly influence static and dynamic properties of the nanoparticles. Therefore, it is critical to understand their properties as a function of the distributions. Previously, we studied an effect of particle size distributions on metastability in magnetization relaxation, using spin $S = 1$ Blume-Capel model with Glauber transition rates. The size distributions were simulated using distributions of magnetic anisotropy parameter D with spins fixed. We found that the lifetime of the metastable state is governed by the smallest particle in a given system. In this talk, we present the effect of size distributions on metastability in magnetization relaxation with phonon-assisted transition rates. These transition rates differ from Glauber dynamics and are derived from weak spin-phonon coupling. In the phonon-assisted transition rates, spin-flips occur via emission or absorption of phonons, and so transitions are forbidden between degenerate states. We investigate magnetization relaxation with distributions of D using kinetic Monte Carlo simulations, when the distributions include values with which such forbidden transitions are expected.

1:27PM Q13.00012 Magnetoelastic coupling in magnetic oxide nanoparticles¹, QI SUN, University of Tennessee, SHEILA BAKER, University of Missouri-Columbia, CHRISTINA BIRKEL, RAM SESHADRI, University of California at Santa Barbara, WOLFGANG TREMEL, Johannes Gutenberg-Universitat, ANDREW CHRISTIANSON, Oak Ridge National Laboratory, JANICE MUSFELDT, University of Tennessee — Phonons are exquisitely sensitive to finite length scale effects in a wide variety of materials. To investigate confinement in combination with strong magnetoelastic interactions, we measured the infrared vibrational properties of MnO and CoFe₂O₄ nanoparticles and their parent compounds. For MnO, a charge and bonding analysis reveals that Born effective charge, local effective charge, total polarizability, and the force constant are overall lower in the nanoparticles compared to the bulk. We find that the spin-lattice coupling drops from $\sim 7 \text{ cm}^{-1}$ in the single crystal to $< 1 \text{ cm}^{-1}$ in the nanoparticles. For CoFe₂O₄, the spectroscopic response is sensitive to the size-induced crossover to the superparamagnetic state, which occurs between 7 and 10 nm, and a spin-phonon coupling analysis supports the core-shell model. Moreover, it provides an estimate of the thickness of the magnetically disordered shell, increasing from 0.4 nm in the 14 nm particles to 0.8 nm in the 5 nm particles, demonstrating that the associated local lattice distortions take place on the length scale of the unit cell. These findings are important for understanding finite length scale effects in magnetic oxides and other more complex functional oxides.

1:39PM Q13.00013 The specific edge effects of 2D core/shell model for spin-crossover nanoparticles¹, AZUSA MURAOKA, Meiji University, KAMEL BOUKHEDDADEN, JORGE LINARÈS, FRANCOIS VARRET, Université de Versailles Saint-Quentin-en-Yvelines — We analyzed the size effect of spin-crossover nanoparticles at the edges of the 2D square lattices core/shell model, where the edge atoms are constrained to the high spin (HS) state. We performed MC simulations using the Ising-like Hamiltonian,

$$H = -J \sum_{\langle i,j \rangle} \sum_{\substack{i' = \pm 1; \\ j' = \pm 1}} S(i,j) S(i+i', j+j') + \left(\frac{\Delta}{2} - \frac{k_B T}{2} \ln g \right) \sum_{\langle i,j \rangle} S(i,j)$$

The molar entropy change is $\Delta S \approx 50 \text{ J/K/mol}$, $\ln g = \Delta S/R \approx 6$ (R is the perfect gas constant), energy gap is $\Delta = 1300 \text{ K}$. The HS fixed edges were based on the observation of an increasing residual HS fraction at low temperature upon particle size reduction. This specific boundary condition acts as a negative pressure which shifts downwards the equilibrium temperature. The interplay between the equilibrium temperature ($= \Delta/k_B \ln g$) variation and the expected variation of the effective interactions in the system leads to a non-monotonous dependence of the hysteresis loop width upon the particle size. We described how the occurrence condition of the first-order transition has to be adapted to the nanoscale.

1:51PM Q13.00014 Magnetic Properties of Single Co Nanoparticles Probed by Tunneling and Microwaves, WENCHAO JIANG, FELIPE TIJIWA BIRK, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology — We present tunneling studies of magnetic hysteresis loops of single Co nanoparticles. The magnetic switching field at mK-temperature is strongly reduced as a function of bias voltage. At 10mV bias voltage, the switching field is reduced by 15%, while the magnetization can be switched by applying a voltage pulse of 10mV. The strong reduction of the switching field is not an artifact due to charge noise or Joule heating, nor it is a result of the electric field dependence of the surface anisotropy. Instead, the reduction represents the case of magnetic excitation driven by the tunnel current. The strength of the effect indicates strongly enhanced coupling between magnetic excitations and the tunnel current in ferromagnets with strongly reduced dimensions. We also present the first measurement of the magnetic relaxation time in a single Co nanoparticle ($\sim$ microsecond), obtained by combining tunneling spectroscopy and microwave pumping.

2:03PM Q13.00015 Exchange Bias Studies in Core/Shell Structures Nanoparticles, HAFSA KHURSHID, SAYAN CHANDRA, University of South Florida, WANFENG LI, University of Delaware, MAN-HUONG PHAN, University of South Florida, GEORGE HADJIPANAYIS, HARIHARAN SRIKANTH, University of Delaware, UNIVERSITY OF DELAWARE COLLABORATION, UNIVERSITY OF SOUTH FLORIDA COLLABORATION — This study is focused on a comparison of magnetic properties of chemically synthesized core/shell structured iron/iron-oxide nanoparticles with different core sizes and comparable shell thickness. Particles were synthesized by high temperature decomposition of iron organometallic compounds. Thermomagnetic data revealed that particles are superparamagnetic at room temperature. The field cooled hysteresis loops showed interesting features of enhanced coercivity and horizontal and vertical shifts along directions of the cooling field, all strongly depend on temperature, indicative of an exchange-bias-like phenomenon. These effects were more pronounced in smaller core size nanoparticles with an exchange bias field of 4098 Oe. The spin-glass-like phase with high-field irreversibility in the iron oxide shells played the role of the fixed phase in the core/shell system and provided the pinning force to the reversible spins. The magnetic domains and higher contributions from the surface anisotropy in the hollow nanoparticles caused enormous magnetic frustration that is the origin of high field irreversibility and vertical shift of hysteresis loop in these particles.

Session Q14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spin Dependent Transport 212

11:15AM Q14.00001 Determination of Rashba and Dresselhaus coefficient in InGaAs quantum wells¹, SÉBASTIEN FANIEL, Université catholique de Louvain, TORU MATSUURA, Hokkaido University, SHUNSUKE MINESHIGE, GSIST, Hokkaido University, YOSHIKI SEKINE, NTT BRL, NTT Corp, TAKAAKI KOGA, GSIST, Hokkaido University — We report the determination of the intrinsic spin-orbit interaction (SOI) parameters for $\text{In}_{0.53}\text{Ga}_{0.47}\text{As}/\text{In}_{0.52}\text{Al}_{0.48}\text{As}$ quantum wells (QWs) from the analysis of the weak antilocalization effect measured at dilution temperature [1]. We found that the Dresselhaus SOI is mostly negligible relative to the Rashba SOI in this system. The intrinsic parameter for the Rashba effect, $a_{\text{SO}} \equiv \alpha/\langle E_z \rangle$, is determined to be $a_{\text{SO}} m^*/m_e = (1.46 - 1.51 \times 10^{-17} N_S [\text{m}^{-2}]) e\text{\AA}^2$, where α is the Rashba SOI coefficient, $\langle E_z \rangle$ is the expected electric field within the QW, m^*/m_e is the electron effective mass ratio, and N_S is the sheet carrier density. The N_S dependence of a_{SO} corresponds to the non-parabolic correction in the effective mass or electron g-factor. These values for $a_{\text{SO}} m^*$, which are in good agreement with the theoretical prediction by Kane's $\mathbf{k} \cdot \mathbf{p}$ theory, were also confirmed by the observation of beatings in the Shubnikov-de Haas oscillations in our most asymmetric QW sample.

11:27AM Q14.00002 Spin-dependent scattering in the presence of polarized nuclei in n-GaAs¹, KEVIN CHRISTIE, CHAD GEPPERT, MUN CHAN, University of Minnesota, QI HU, CHRIS PALMSTRØM, University of California, Santa Barbara, PAUL CROWELL, University of Minnesota — We report on all-electrical measurements of the inverse spin Hall effect (ISHE) in epitaxial (100) Fe/GaAs heterostructures with a channel doping (Si) of $n = 5 \times 10^{16} \text{ cm}^{-3}$ and highly doped Schottky tunnel barriers. Under measurement conditions of large (10-20%) spin accumulation at the injection electrode, a significant dynamic nuclear polarization (DNP) enhances the size of the ISHE. The electron spin dynamics are shown to match the predictions of the usual drift-diffusion model, including the applied, hyperfine, and Knight fields. The DNP, however, also enhances the scattering of spin-polarized carriers, which is not understood. To separate the roles of the electronic and nuclear spin systems, we have employed a pump-probe method to vary the nuclear spin polarization $\langle I \rangle$ and electron spin polarization S independently. The size of the ISHE is proportional to $\langle I \rangle$ when the DNP is small, but it eventually saturates. When the nuclear polarization is fixed, the ISHE is linear in S , as expected. We conclude therefore that the measured signal scales linearly with the spin current multiplied by a transport skewness parameter that depends strongly on $\langle I \rangle$.

11:39AM Q14.00003 Nuclear enhancement of the spin Hall angle in $n\text{-In}_x\text{Ga}_{1-x}\text{As}$ ¹, CHAD GEPPERT, KEVIN CHRISTIE, MUN CHAN, University of Minnesota, QI HU, CHRIS PALMSTRØM, University of California at Santa Barbara, PAUL CROWELL, University of Minnesota — We present measurements of the inverse spin Hall effect in vertical $\text{Fe}/\text{In}_x\text{Ga}_{1-x}\text{As}$ heterostructures as identified via a Hanle effect in the local Hall voltage. The spin Hall angle is greatly enhanced in the presence of polarized nuclei, achieving typical values of $\gamma \simeq 5 \times 10^{-2}$. Phenomenological modeling of the observed line-shapes shows that the nuclear polarization acts as a linear prefactor to the standard spin Hall conductivity. This enhancement far exceeds expectations based on the energy splitting of the electron or nuclear spin systems. Our samples are doped just above the Mott transition ($n \simeq 3n_c$) where metallic impurity band conduction is dominant. A strong coupling between localized moments and delocalized states is evidenced by the temperature dependence and sensitivity to disorder at higher In concentrations. This leads us to interpret our results using an Anderson-like model of polarized impurities whereby both dynamic nuclear polarization and resonant skew scattering arise as a result of a spin polarized doubly occupied (D^-) impurity band.

11:51AM Q14.00004 Spin Hall effect for detection of spin-currents – Realization of a Spin transistor, JOERG WUNDERLICH, Hitachi Cambridge Laboratory, Cambridge CB3 0HE, UK; Institute of Physics ASCR, v.v.i., Cukrovarnická 10, 162 53 Praha 6, Czech Republic — The realization of a viable semiconductor transistor and information processing devices based on the electron spin has fueled intense basic research of three key elements: injection, detection, and manipulation of spins in the semiconductor microchannel. The inverse spin Hall effect (iSHE) detection of spins manipulated by a gate electrode [1] has recently led to the experimental demonstration of a spin transistor device. [2] Here, the spin injection into a 2-dimensional electron gas (2DEG) was done optically in the depletion layer of a reverse biased pn-junction. [3] The iSHE detection is also used for electrical spin injection from a Fe electrode into a lateral GaAs channel combined with a simultaneous non-local spin valve measurement [4-10]. The spins in the channel are manipulated via the Hanle spin precession induced by an applied magnetic field and via a drift of electrons induced by an applied electric field. The output spin signal is suppressed or enhanced depending on the applied electrical bias rendering the device to a spin transistor different from the Datta Das concept. [11]

12:27PM Q14.00005 Measurement by antilocalization of interactions between InAs surface electrons and magnetic surface species¹, YAO ZHANG, R.L. KALLAHER, V. SOGHOMONIAN, J.J. HEREMANS, Virginia Tech — Weak-antilocalization (WAL) low-temperature magnetotransport measurements are sensitive to electron quantum coherence, and can be used as a sensitive probe of surface quantum states. We experimentally study interactions between surface electrons and local magnetic moments on InAs by comparing WAL on patterned InAs accumulation layers where rare earth ions or Co^{2+} , Co-phthalocyanine, Fe^{3+} , and Fe-phthalocyanine were deposited, with those where no magnetic species were deposited. The magnetic species modify the magnetic spin-flip scattering, which carries information about magnetic interactions, and modify the spin-orbit (SO) scattering, identified via the WAL signal and characterized over temperature. Experiments indicate a mostly temperature-independent magnetic spin-flip scattering, except for Ho^{3+} . The SO scattering also displays a weak temperature dependence, and is increased by the heavy ions, Co^{2+} and Co-phthalocyanine, while suppressed by ferromagnetic Fe^{3+} and Fe-phthalocyanine, in agreement with the expected absence of the WAL in ferromagnets.

12:39PM Q14.00006 A Quantitative Analysis of the Electrical Detection of Spins Via the Spin Hall Effect and the Non-Local Spin Valve Effect Within a Semiconductor Microchannel, VIVEK AMIN, JAIRO SINOVA, Department of Physics, Texas A&M University, JOERG WUNDERLICH, Hitachi Cambridge Laboratory, ANDY IRVINE, Microelectronics Research Centre, Cavendish Laboratory, RICHARD CAMPION, School of Physics and Astronomy, University of Nottingham, KAMIL OLEJNIK, TOMAS JUNGWIRTH, Institute Of Physics ASCR — Recently, the manipulation of spins via a gate electrode, and their subsequent detection through the Spin Hall Effect, has led to the experimental realization of a spin-based semiconductor transistor. While in this experiment, spin injection was achieved optically via circularly-polarized light, we consider a similar experiment using electrical injection by means of a ferromagnetic contact into a GaAs microchannel instead. The spin current in a lateral semiconductor channel is then detected through the Spin Hall Effect, while the spin accumulation nearby is simultaneously measured through the Non-Local Spin Valve Effect (using another Fe electrode). The spins within the channel are manipulated through the Hanle Effect via an external magnetic field, and through a drift induced by an applied electrical bias. To analyze these results, we use analytical and numerical solutions to the steady-state drift-diffusion equations with a constant magnetic field and a drift velocity modeled by a Heaviside Theta function. Combining these results with the anomalous Hall response function, which takes into account the geometry of the Hall probe in order to obtain the correct Hall angle, we obtain results that are in quantitative agreement with experiments.

12:51PM Q14.00007 Spin-gating of a conventional aluminum single electron transistor, LIVIU P. ZÂRBO, Institute of Physics ASCR, v.v.i., CZ, CHIARA CICCARELLI, ANDY IRVINE, Microelectronics Group, Cavendish Laboratory, University of Cambridge, UK, JÖRG WUNDERLICH, Hitachi Cambridge Laboratory, Cambridge, UK, RICHARD CHAMPION, BRIAN GALLAGHER, School of Physics and Astronomy, University of Nottingham, UK, TOMÁŠ JUNGWIRTH, Institute of Physics ASCR, v.v.i., CZ, ANDREW FERGUSON, Microelectronics Group, Cavendish Laboratory, University of Cambridge, UK — We report the realization of a single electron transistor in which electron transport from an aluminum source electrode to an aluminum drain electrode via an aluminum island is controlled by spins in a capacitively coupled magnetic gate electrode. The origin of the effect is in the change of the chemical potential on the gate, formed by the ferromagnetic semiconductor GaMnAs, with changing the direction of the magnetization. In agreement with experimental observations, microscopically calculated anisotropies of the chemical potential with respect to the magnetization orientation are of the order of $10\mu\text{V}$ which is comparable to the electrical gate voltages required to control the on and off state of the single electron transistor. Our phenomenon belongs to the family of anisotropic magnetoresistance effects which can be observed in ohmic, tunneling or other device geometries. In our case, the entire phenomenon is coded in the dependence of the chemical potential on the spin orientation which allowed us to remove the spin functionality from all current contacts and channels and place it in the capacitively coupled gate electrode. Our spintronic device therefore operates without spin current.

1:03PM Q14.00008 Spin injection from into InSb from CoFe, YONG-JAE KIM, MARTIN RUDOLPH, R.L. KALLAHER, J.J. HEREMANS, Virginia Tech — The strong spin-orbit interaction in InSb is an asset for spin manipulation using electric fields. In order to electrically characterize spin injection and detection in InSb, we experimentally investigate spin injection into InSb from ferromagnetic CoFe electrodes, via non-local spin valve measurements at low temperature. We observe non-local transresistance switching around zero in-plane external magnetic field. We characterize the magnetic properties of the CoFe layer by the Hall signal of the fringing fields and confirm 3-state switching. We verify that the non-local signal is not related to the physical or geometrical magnetoresistance due to the CoFe fringing fields. The non-local spin valve signal is, as typical, dependent on the specific CoFe/InSb interfaces, while the temperature dependence points to a contribution beyond the spin coherence length. We further observe a modification of weak-antilocalization by spin injected carriers and the same phenomenon may contribute to the spin valve transresistance (partial support from DOE DE-FG02-08ER46532).

1:15PM Q14.00009 Top- and Side-Gated InAs Spinfilter Cascades in Magnetic Fields, JAN JACOB, HAUKE LEHMANN, TILL BENTER, ALEXANDER BUHR, JENS KIENITZ, ULRICH MERKT, Universitaet Hamburg, Institut fuer Angewandte Physik — We present results from transport experiments on two-stage Y-shaped spin-filter cascades fabricated from InAs heterostructures. The first Y junction acts as a generator of two oppositely spin-polarized currents by employing the intrinsic spin-Hall effect. When the second filter that is attached to one of the first filter's outputs in a distance corresponding to a multiple of the spin-precession length, the spin polarization is revealed as a conductance imbalance at the outputs. To achieve the required quasi one-dimensional transport modes we reduce either the effective width of the cascade's five wires by side-gate quantum-point contacts or we reduce the carrier concentration by means of a top gate. The latter yields the advantage to keep the width along the cascade's wires constant and thus, by ensuring higher homogeneity of the potential, reduces spurious effects in the measured conductances. The application of a magnetic field perpendicular to the cascade's plane results in a Lorentz force acting on the electrons in the cascade and thereby changing the measured conductance imbalance and the spin polarization. This can be used to quantify the strength of the spin-Hall effect in InAs heterostructures.

1:27PM Q14.00010 Tunable Zeeman-like Spin Splitting with Liquid Gated Field Effect Transistors, HONGTAO YUAN, Department of Applied Physics, University of Tokyo, M.S. BAHRAMY, Correlated Electron Research Group, RIKEN, K. MORIMOTO, H. SHIMOTANI, R. ARITA, University of Tokyo, CH. KLOC, Nanyang Technological University, N. NAGAOSA, Y. IWASA, University of Tokyo — Generation of spin polarized electrons is the most critical step for developing spintronics applications. As an electric and nonmagnetic way to realize spin polarization in energy bands, spin-orbit interaction (SOI) has been widely used for spin manipulation in two-dimensional systems. For example, Rashba-type energy splitting with in-plane-polarized spins near Γ point of Brillouin zone (BZ) is able to be modulated by electric field through tuning spatial inversion asymmetry. However, Zeeman-type energy splitting with out-of-plane spin polarization is known to be sensitive only to magnetic field and supposed never to be affected by external electric field. In this paper, we theoretically uncover and experimental confirm a perpendicular-electric-field induced giant Zeeman spin splitting at low symmetric K and K' points in a layered chalcogenide, 2H-WS_2 . *Ab initio* band calculation and spin texture indicate that an electric field can make low-energy carriers spin-polarized in a out-of-plane Zeeman-type way and a tunable SOI is able to selectively control the size of splitting. A gate-induced crossover from weak localization to weak antilocalization in the magnetotransport serves as an experimental proof for the tunable SOI and spin polarization. The splitting energy deduced from quantum correction of magnetoconductance is as large as 120 meV and satisfied well with the band calculation for Zeeman-type splitting. This finding directly provides us with a new path-way for electrically initializing and manipulating electron spins for spintronics applications.

1:39PM Q14.00011 Anomalous Hall effect in the Presence of Strong Spin-orbit Coupling and Non-trivial Magnetization, JIANPING LIU, HUAWEI GAO, JACOB GAYLES, ARTEM ABANOV, JAIRO SINOVA, Texas A&M University — AHE in ferromagnets with strong spin-orbit coupling (SOC) and homogeneous magnetization has been studied extensively, using both Kubo formalism and semi-classical Boltzmann equation. In the opposite limit of weak SOC in the presence of non-trivial magnetization texture and strong exchange coupling with the carriers (adiabatic limit), the electron spins always align themselves with the direction of the local magnetization and they experience an effective magnetic field arising from this non-trivial magnetization, giving rise to the topological anomalous Hall effect. We study here the transition between the two limits and the joint effect that a strong SOC and non-trivial magnetic textures have on the AHE. We will report on results from both perturbative analytical approaches and bulk numerical simulations. Some of these effects may be present and exploited in current induced manipulation and detection of domain walls.

1:51PM Q14.00012 Spin diffusion and precession at the multiferroic interface and InAs quantum wells, PENG ZHANG, MING-WEI WU, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, University of Science and Technology of China — We study spin diffusion and precession in a two-dimensional electron gas at the multiferroic interface and InAs quantum wells respectively by means of the kinetic spin Bloch equation approach [Wu *et al.*, Physics reports **493**, 61 (2010)]. At the $\text{AlO}_3/\text{SrTiO}_3/\text{TbMnO}_3$ heterostructure with a temperature being as low as 15 K, the two-dimensional electron gas at the $\text{LaAlO}_3/\text{SrTiO}_3$ interface interacts with the spiral magnetic moments of Mn^{3+} in TbMnO_3 via the Heisenberg exchange interaction. It is demonstrated that the spin diffusion length at the interface is always finite, despite the polarization direction of the injected spins. It is also revealed that the Coulomb scattering plays an important role and effectively suppresses the spin diffusion. The spin precession in InAs quantum wells is investigated with the Rashba spin-orbit coupling being modulated by a gate voltage. The gate-voltage dependence of spin diffusion under different temperatures is studied with all the scattering explicitly included. Our result partially supports the claim of the realization of the Datta-Das spin-injected field effect-transistor by Koo *et al.* [Science **325**, 1515 (2009)]. We also show that the scattering plays an important role in spin diffusion in such a system.

2:03PM Q14.00013 Enhanced photon-assisted spin transport in a quantum dot attached to ferromagnetic leads¹, FABRICIO M. SOUZA, Instituto de Fisica, Universidade Federal de Uberlandia, THIAGO L. CARRARA, Universidade Federal do Triangulo Mineiro, EDSON VERNEK, Instituto de Fisica, Universidade Federal de Uberlandia — Time-dependent transport in quantum dot system (QDs) has received significant attention due to a variety of new quantum physical phenomena emerging in transient time scale.[1] In the present work [2] we investigate real-time dynamics of spin-polarized current in a quantum dot coupled to ferromagnetic leads in both parallel and antiparallel alignments. While an external bias voltage is taken constant in time, a gate terminal, capacitively coupled to the quantum dot, introduces a periodic modulation of the dot level. Using non equilibrium Green's function technique we find that spin polarized electrons can tunnel through the system via additional photon-assisted transmission channels. Owing to a Zeeman splitting of the dot level, it is possible to select a particular spin component to be photon-transferred from the left to the right terminal, with spin dependent current peaks arising at different gate frequencies. The ferromagnetic electrodes enhance or suppress the spin transport depending upon the leads magnetization alignment. The tunnel magnetoresistance also attains negative values due to a photon-assisted inversion of the spin-valve effect. [1] F. M. Souza, Phys. Rev. B **76**, 205315 (2007). [2] F. M. Souza, T. L. Carrara, and E. Vernek, Phys. Rev. B **84**, 115322 (2011).

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q16 DCMP: Heavy Fermions - 1-1-5 Systems 251

11:15AM Q16.00001 Strong magnetic fluctuations in superconducting state of CeCoIn_5 ¹, T. HU, H. XIAO², M. DZERO, C.C. ALMASAN, Kent State University, Kent, OH, T.A. SAYLES, M.B. MAPLE, University of California at San Diego, CA — We probe the magnetism inside the superconducting state of CeCoIn_5 by locally suppressing superconductivity and investigating the underlying normal state through current-voltage measurements under applied pressure and external magnetic field in the mixed state. We observe that the vortex core resistivity increases sharply with decreasing temperature (T) for $T < T_c$ and magnetic field. We attribute this result to the presence of critical spin fluctuations near the Neel temperature inside the vortex core. This behavior is greatly suppressed with increasing pressure, due to the suppressed antiferromagnetic order inside the vortex core. Using our experimental results we construct a three-dimensional phase diagram which provides a direct evidence for a quantum critical line inside the superconducting phase. An experimentally obtained explicit equation for the antiferromagnetic boundary inside the superconducting dome shows the close relationship between quantum criticality, antiferromagnetism, and superconductivity.

11:27AM Q16.00002 Visualizing the Emergence of Heavy Fermions in a Kondo Lattice (Part I)¹, EDUARDO H. DA SILVA NETO, PEGOR AYNAJIAN, Princeton University, RYAN BAUMBACH, J.D. THOMPSON, Los Alamos National Laboratory, ZACHARY FISK, University of California, Irvine, ERIC BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — The interaction between magnetic moments and conduction electrons is at the heart of many phenomena in condensed matter physics, from the Kondo effect in magnetic alloys and nanostructures to superconductivity in strongly correlated systems. We use the scanning tunneling microscope (STM) to detect the emergence of these heavy excitations with lowering of temperature in a prototypical 115 family of Ce-based heavy fermion compounds. Experiments on different atomically terminated layers and their modeling are used to demonstrate the sensitivity of the tunneling process to the composite nature of these heavy quasiparticles, which arise from quantum entanglement of itinerant conduction and f -electrons. The momentum space electronic structure of those heavy excitations will be discussed in the next talk by Pegor Aynajian.

¹This work is funded by a DOE-BES grant. Infrastructure at the Princeton Nanoscale Microscopy Laboratory are also supported by grants from NSF-DMR, Keck Foundation, and NSF-MRSEC.

11:39AM Q16.00003 Visualizing the Emergence of Heavy Fermions in a Kondo Lattice (Part II) , PEGOR AYNAJIAN, EDUARDO DA SILVA NETO, Princeton University, RYAN BAUMBACH, JOE THOMPSON, Los Alamos National Laboratory, ZACHARY FISK, University of California Irvine, ERIC BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — The development of low energy fermionic excitations with heavy mass in compounds with f -orbitals is one of the key concepts in the physics of correlated electronic states and fundamental to the mechanism of unconventional superconductivity in such systems. We use spectroscopic mapping with the scanning tunneling microscope (STM) to detect the emergence of these heavy excitations in the Ce-115 heavy fermion compounds. Scattering and interference of the heavy quasiparticles is used to resolve their energy-momentum structure and to extract their mass enhancement, which develops near the Fermi energy with decreasing temperature. This work is funded by a DOE-BES grant. Infrastructure at the Princeton Nanoscale Microscopy Laboratory are also supported by grants from NSF-DMR, Keck Foundation, and NSF-MRSEC. PA also acknowledges support of a fellowship through the PCCM funded by NSF MERSEC.

11:51AM Q16.00004 Scanning tunneling microscopy studies of heavy fermion compound CeCo(In_{1-x}Cd_x)₅ , ANDRAS GYENIS, PEGOR AYNAJIAN, EDUARDO H. DA SILVA NETO, Princeton University, ZACHARY FISK, University of California, Irvine, ERIC D. BAUER, Los Alamos National Laboratory, ALI YAZDANI, Princeton University — Heavy fermion materials, such as those forming in actinide- or lanthanide-based compounds, have a rich variety of phases from unconventional superconductivity to antiferromagnetism to possibly exotic and non-Fermi liquid states. Central to all these ground states is the interaction between the magnetic impurities and the conduction electrons. In the Ce-based heavy fermions compounds (e.g. CeColn₅), the ground state can be tuned by doping or isovalent substitution, for example, Cd doping tunes the system toward antiferromagnetism. We present scanning tunneling microscopy/spectroscopy measurements on the Cd-doped CeColn₅ heavy fermion compounds as a function of temperature. These results will be analyzed within the context of how tuning the chemical structure impacts the formation of heavy electron band and various ground states of this material system.

12:03PM Q16.00005 Magnetic penetration depth and skin depth study of superconductivity and quantum criticality in Ce_{1-x}R_xCoIn₅ (R=La and Nd) , HYUNSOO KIM, M. A. TANATAR, K. CHO, J. MURPHY, R. PROZOROV, The Ames Laboratory, Ames, IA, R. HU, C. PETROVIC, Brookhaven National Laboratory, Upton, NY — A heavy fermion superconductor CeColn₅ shows different responses to Nd- or La- substitutions for Ce, with the former inducing static magnetic order coexisting with superconductivity for some concentrations. To understand the origin of the differences, we studied the temperature and field dependent in-plane magnetic penetration depth, $\lambda(T)$, in single crystals of (Ce,R)Coln₅ (R=La, Nd). Measurements were performed with a tunnel diode resonator down to 50 mK in a dilution refrigerator, in magnetic field up to 14 T parallel to the c -axis. These low-temperature and high field measurements allowed for the exploration for the full domain of superconductivity and quantum criticality in the $T-H$ phase diagram. Some previously unreported features were observed and will be discussed from the point of view of measured differential magnetic susceptibility. Combined with the contact-less measurements of resistivity via normal-state skin depth, these measurements bring new insight into the interplay between superconductivity and magnetism as well as field-tuned quantum critical behavior of doped 115 systems.

12:15PM Q16.00006 Quantum oscillations study of the Fermi-surface evolution in Yb-substituted CeCoIn₅ , BOBBY PRÉVOST, Département de physique, Université de Montréal, Montréal, QC, Canada, ANDREY POLYAKOV, OLEG IGNATCHIK, Hochschule-Magnetlabor Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, SIMON BLACKBURN, ANDREA D. BIANCHI, MICHEL CÔTÉ, GABRIEL SEYFARTH, Département de physique, Université de Montréal, Montréal, QC, Canada, DANIEL HURT, ZACHARY FISK, Department of Physics & Astronomy, University of California Irvine, Irvine, CA, USA, ROY G. GOODRICH, Department of Physics, George Washington University, Washington, DC, USA, JOCHEN WOSNITZA, Hochschule-Magnetlabor Dresden (HLD), Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — We report results of systematic de Haas-van Alphen (dHvA) studies on Ce_{1-x}Yb_xColn₅ single crystals with varying Yb concentrations x . For a low dilution of $x = 0.1$, the well-documented Fermi surface and the heavy effective masses of CeColn₅ ($x = 0$) remain nearly unchanged. A clear change of the Fermi-surface topology becomes evident for high Yb concentrations of $x = 0.55$, and above. The effective masses are reduced considerably to values between 0.7 and 2.6 free electron masses. Nevertheless, the superconducting transition temperature T_c and upper critical field H_{c2} are only weakly suppressed with x . The angular-resolved dHvA frequencies for YbColn₅ show a good agreement with our density functional theory band-structure calculation with localized 4f electrons and an Yb valence of 2+, which has been used to constructed the Fermi surface.

12:27PM Q16.00007 Field induced QCP in Yb-doped CeCoIn₅¹ , Y.P. SINGH, T. HU, H. XIAO², M. DZERO, C.C. ALMASAN, Kent State University, L. SHU, M.B. MAPLE, University of California San Diego — We performed magnetoresistance and Hall effect measurements on Yb-doped CeColn₅. The longitudinal resistivity data measured in 14 T show that the onset of coherence in the dilute Kondo lattice remains robust with respect to Yb concentration. In addition, we find that the superconducting transition temperature is weakly suppressed with doping ($x \leq 0.2$). Our analysis of the magnetoresistance data allowed us to identify the magnetic field induced quantum critical point and its evolution upon doping. At high Yb concentrations, our Hall effect data point to a possible valence transition of Yb ions. At small doping, our results provide an insight into the nature of the interplay between quantum criticality, magnetism, and unconventional superconductivity, while the behavior of this system at high doping can be characterized by a subtle interplay between Kondo screening on Ce sites and strong valence fluctuations on Yb sites.

12:39PM Q16.00008 Effect of local electronic tuning in CeCoIn₅ , KRZYSZTOF GOFRYK, FILIP RONNING, M.N. OU, PAUL TOBASH, XIN LU, ERIC BAUER, JOE THOMPSON, Los Alamos National Lab, S. STOYKO, A. MAR, University of Alberta, ZACH FISK, UC Irvine — The relationship between quantum criticality (QC), non-Fermi-liquid (nFL) behavior and the emergence of unconventional superconductivity (SC) in the vicinity of an antiferromagnetic quantum critical point (QCP) is one of the important issues in strongly correlated electron physics. Here we report on the effect of electronic tuning on superconductivity and quantum criticality in CeColn₅ driven by electron (Pt and Sn) and hole doping (Hg). We show that both Pt and Sn doping have similar strong effect on superconductivity and push the system slightly away from the QCP . The sub-linear power law exponent, even at a high doping level (where the superconductivity is suppressed) could point to the formation of electronic inhomogeneity. Moreover, hole doping by Hg can tune the system back to the QCP as demonstrated by an increase of T_c (and subsequently the onset of AFM), a decrease of the coherence temperature T^* and an increase of the power law coefficient n stressing the importance of the interplay of electronic tuning and pair breaking effects.

12:51PM Q16.00009 Doping effects of CeCo_{1-x}Ru_xIn₅ , M.N. OU, Los Alamos National Laboratory; Institute of Physics-Academia Sinica, Y.Y. CHEN, Institute of Physics-Academia Sinica, O. JANKA, S.M. KAUZLARRICH, University of California, K. GOFRYK, R.E. BAUMBACH, E.D. BAUER, J.D. THOMPSON, F. RONNING, Los Alamos National Laboratory — CeColn₅ lies in close proximity to a QCP which can be tuned with chemical doping, pressure or magnetic field. In this work, single crystals of Ruthenium doped CeColn₅ were prepared by means of self-flux in Indium. The lattice structure of CeCo_{1-x}Ru_xIn₅ was identified as tetragonal by powder XRD with slightly increasing lattice constants. The results of electrical resistivity down to 1.8 K reveals that both coherence (T^*) and superconducting transition (T_c) temperatures are decreasing monotonically with increasing Ru doping. Antiferromagnetism is anticipated on the basis of both negative chemical pressure and hole doping. Transport and thermodynamic data will be compared and contrasted with results from Rh and Cd doping.

1:03PM Q16.00010 Effect of Pressure on Superconductivity and the Kondo-Lattice Coherence Temperature in $\text{Ce}_{1-x}\text{R}_x\text{CoIn}_5$ with $\text{R} = \text{Yb}, \text{Y}, \text{Gd}$, BENJAMIN WHITE, JAMES HAMLIN, MARC JANOSCHEK, LEI SHU, RYAN BAUMBACH, KEVIN HUANG, M. BRIAN MAPLE, University of California, San Diego — Generally, rare-earth substitution for Ce in the heavy fermion superconductor CeCoIn_5 suppresses superconductivity rapidly. However, it was recently reported that the correlated electron ground state of $\text{Ce}_{1-x}\text{Yb}_x\text{CoIn}_5$ is stabilized over an anomalously large range in x , perhaps because of cooperative valence fluctuations of the Ce and Yb ions. Motivated by this possibility, we studied the effect of applied pressure on the superconducting critical (T_c) and Kondo-lattice coherence (T^*) temperatures of $\text{Ce}_{1-x}\text{R}_x\text{CoIn}_5$ with $\text{R} = \text{Yb}, \text{Y}$, and Gd in order to compare the effect of Yb substitution with other magnetic and non-magnetic rare-earth ion substitutions. We performed electrical resistivity measurements under pressures up to a maximum of ~ 2.3 GPa in a piston-cylinder clamped high pressure cell using a 50:50 mixture of n -pentane and isoamyl alcohol for the pressure transmitting medium. It was found that the variations of T_c and T^* in $\text{Ce}_{1-x}\text{R}_x\text{CoIn}_5$ under pressure were approximately independent of R . This result implies that the effect of pressure is independent of the magnetic configuration of the rare-earth ion being introduced.

¹Sample synthesis was supported by DOE Grant DE-FG02-04-ER46105. High pressure measurements were supported by DOE grant DE-FG52-06NA26205. Low-temperature measurements were supported by NSF Grant DMR-0802478.

1:15PM Q16.00011 Antiferromagnetic Order in Pauli-Limited Unconventional Superconductors , YASUYUKI KATO, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA, ILYA VEKHTER, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana, 70803, USA — We develop a theory of the coexistence of superconductivity (SC) and antiferromagnetism (AFM) in CeCoIn_5 . We show that in Pauli-limited nodal superconductors the nesting of the quasiparticle pockets induced by Zeeman pair breaking leads to incommensurate AFM with the magnetic moment normal to the field. We compute the phase diagram and find a first order transition to the normal state at low temperatures, the absence of normal state AFM, and the coexistence of SC and AFM at high fields, in agreement with experiments. We also predict the existence of a new double-Q magnetic phase.

1:27PM Q16.00012 Staggered moments in the vortex cores of CeCoIn_5 , L. LU, G. KOUTROULAKIS, M.D. STEWART, V.F. MITROVIĆ, Department of Physics, Brown University, Providence, Rhode Island 02912, M. HORVATIĆ, C. BERTHIER, Grenoble High Magnetic Field Laboratory, CNRS, B.P. 166, 38042 Grenoble Cedex 9, France, G. LAPERTOT, J. FLOUQUET, CEA, INAC, SPSMS, CEA Grenoble, 38054 Grenoble Cedex 9, France — Our previous nuclear magnetic resonance measurements revealed that magnetic field can induce an exotic superconducting phase, characterized by the presence of strong antiferromagnetic fluctuations. In the low field superconducting state, NMR spectra are determined by the inhomogeneous field distribution of a vortex lattice. In the exotic superconducting phase the NMR spectra broaden well beyond what is expected on the basis of the vortex lattice distribution. Here we explore the possibility that this extra broadening of the NMR spectra arises from the staggered magnetization induced locally around the vortex cores.

1:39PM Q16.00013 Knight Shift anomaly in anti-ferromagnetic Heavy Fermion, CeRhIn_5 , ABIGAIL SHOCKLEY, University of California, Davis — Since their discovery, the CeMIn_5 ($\text{M}=\text{Ir}, \text{Rh}, \text{Co}$) class of heavy fermion superconductors has attracted a lot of attention for their unusual properties. These compounds all have a scaling behavior which Nakatsuji et al (NPF) proposed is best explained by a two-fluid model. Below a characteristic temperature T^* , the f-moments delocalize and form a coherent state with the conduction electrons, similar to super-fluid ^4He . One of the central questions in the field is which energy scale correlates with the onset of coherence, T_{Kondo} or T_{RKKY} . We will present new data on the Knight Shift anomaly in CeRhIn_5 which allows us to learn about the spin correlations as we approach the coherent state. By comparing the Knight shift anomaly in the three cousin compounds, we can explore how the characteristic energy scales of these materials change as we transition from a superconducting to an anti-ferromagnetic ground state.

1:51PM Q16.00014 Strong suppression of superconductivity and Kondo coherence by Yb substitution in CeCoIn_5 epitaxial films , MASAOKI SHIMOZAWA, SATOSHI YASUMOTO, Department of Physics, Kyoto University, MASAYUKI NAKAMURA, RCLTMS, Kyoto University, TATSUYA WATASHIGE, YUTA MIZUKAMI, Department of Physics, Kyoto University, HIROAKI SHISHIDO, Department of Physics and Electronics, Osaka Prefecture University, TAKASADA SHIBAUCHI, Department of Physics, Kyoto University, TAKAHITO TERASHIMA, RCLTMS, Kyoto University, YUJI MATSUDA, Department of Physics, Kyoto University — One of the important issues in strongly correlated electron system is the relationship between unconventional superconductivity and quantum criticality. Among them, the heavy-fermion superconductor CeCoIn_5 is a key material situated near an antiferromagnetic quantum critical point. When rare-earth ions are substituted for Ce, superconductivity and Kondo-lattice coherence are usually suppressed, but it has been recently pointed out from bulk studies that Yb substitution may be distinguished because of its valence instability. Here we report our recent study on $\text{Ce}_{1-x}\text{Yb}_x\text{CoIn}_5$ epitaxial thin films grown by the molecular beam epitaxy, which have high homogeneity. We find that the superconducting transition temperature is suppressed with increasing x much more rapidly than the previous bulk results, and that the coherence temperature is suppressed concurrently. We also observe a systematic reduction of the low-temperature Hall coefficient magnitude with x , establishing that the antiferromagnetic fluctuations fade even by the Yb substitutions.

2:03PM Q16.00015 Extremely strong-coupling superconductivity in artificial two-dimensional Kondo lattices , YUTA MIZUKAMI, Department of Physics, Kyoto University, HIROAKI SHISHIDO, Research Center for Low Temperature and Materials Sciences, Kyoto University, TAKASADA SHIBAUCHI, MASAOKI SHIMOZAWA, SATOSHI YASUMOTO, DAIKI WATANABE, MINORU YAMASHITA, HIROAKI IKEDA, Department of Physics, Kyoto University, TAKAHITO TERASHIMA, Research Center for Low Temperature and Materials Sciences, Kyoto University, HIROSHI KONTANI, Department of Physics, Nagoya University, YUJI MATSUDA, Department of Physics, Kyoto University — Superconductivity with the strongest electron correlations is realized in heavy-fermion system, where almost all of the compounds have three-dimensional nature. It had remained an unanswered question whether superconductivity would persist on reducing the dimensionality of these materials. We succeeded in observing superconductivity in the system of heavy electrons confined within a two dimensional square lattice of Ce atoms, which was realized by fabricating epitaxial superlattices built of alternating layers of heavy-fermion CeCoIn_5 and conventional metal YbCoIn_5 [1]. The field-temperature phase diagram of the superlattices exhibits a striking enhancement of the upper critical field relative to the transition temperature. This implies that the force holding together the superconducting electron pairs takes on an extremely strong-coupled nature as a result of two-dimensionalization. Session Q17 DMP: Focus Session: Nanostructures and Metamaterials, Growth, Structure, and Characterization – Improved Materials and Applications I 252A

11:15AM Q17.00001 Metamaterials and Plasmonics: Improved Material Building Blocks, ALEXANDRA BOLTASSEVA, Purdue University — Optical metamaterials are rationally designed and manufactured materials built of nanostructured unit cells, or “artificial atoms” much smaller than the wavelength of operating light. These materials can be engineered to exhibit optical properties beyond any naturally occurring materials. This field has been gaining momentum over the past several years, as it continues to provide new fascinating ideas promising a variety of exciting applications including for example super-resolution microscopes, extremely efficient light concentrators and invisibility cloaks. In most metamaterial devices, noble metals (primarily gold and silver) have been used as the constituent material to make subwavelength building blocks. But metals suffer from high optical losses that are much too large to create practical and robust metamaterials devices. A recent approach that could unlock the technological potential of plasmonics and optical metamaterials is to look for better plasmonic materials that have a negative real part of dielectric permittivity. Here we provide an overview of two classes of alternative plasmonic materials - doped semiconductors and intermetallics - that could allow realization of novel transformation optics and metamaterial devices with greatly improved performance operating at near infrared and visible frequencies.

11:51AM Q17.00002 Bianisotropy Compensation in Metamaterials, GEORGE KEISER, ANDREW STRIKWERDA, Department of Physics-Boston University, KEBIN FAN, XIN ZHANG, Department of Mechanical Engineering- Boston University, RICHARD AVERITT, Department of Physics- Boston University — The potential scientific and technological applications for metamaterials abound and continue to multiply at an unprecedented rate. However, with applications come non-trivial design challenges. For instance, many metamaterial designs exhibit the phenomenon of bianisotropy, the ability for an incident electric field to excite a magnetic response (and vice versa) in the metamaterial. In many applications, this bianisotropic response is considered a parasitic effect to be avoided whenever possible. Metamaterials can be designed to eliminate bianisotropy at the unit cell level, but the presence of a substrate will inevitably reintroduce bianisotropy into the system. Here, through a judicious choice of unit cell geometry, we have compensated for and removed the effects of substrate-induced bianisotropy in broadside coupled split-ring resonators on a GaAs substrate. We present numerical simulation results, parameter extraction, and experimental measurements at terahertz frequencies to validate this claim.

12:03PM Q17.00003 Indium Tin Oxide Nanorod Building Blocks for Near-Infra-Red Filter Metamaterials¹, SUNG HOON HONG, HUMEYRA CAGLAYAN, NADER ENGHETA, CHERIE KAGAN, University of Pennsylvania — We report arrays of indium tin oxide (ITO) nanorods function as near-infra-red (NIR) filter metamaterials. We fabricated arrays of rectangular cross-section, plasmonic ITO nanorods of varying pitch, width, gap, and height of the nanorods using nanoimprint lithography and chlorine based inductively coupled plasma (ICP) etching processes. The transmission spectrum of the periodic nanorod arrays may be spectrally tuned in the NIR by the geometry of the arrays and the optical response depends on the polarization of the incident light. The nanorod array behaves as an optical nanocircuit. For illumination by an E-field vector parallel to the nanorod array, the array functions as a parallel L-C circuit, acting as a bandpass filter. For illumination by an E-field vector perpendicular to the nanorod array, the array functions as a series L-C circuit, acting as a bandstop filter. We show good agreement between optical measurements of fabricated nanorod arrays and simulations using equivalent circuit theory and finite-difference time-domain (FDTD) methods. The optical properties of the ITO nanorod circuit may be further tuned by filling the gap between the nanorods using various dielectric materials.

12:15PM Q17.00004 Measurement of Resonant Frequencies and Modes of Freestanding Nanoparticle Monolayers, PONGSAKORN KANJANABOOS, James Franck Institute and Department of Physics, The University of Chicago, XIAO-MIN LIN, Center for Nanoscale Materials, Argonne National Laboratory, HEINRICH JAEGER, James Franck Institute and Department of Physics, The University of Chicago, JEFFREY GUEST, Center for Nanoscale Materials, Argonne National Laboratory — We recently showed that freestanding membranes of ligated nanoparticles can be assembled in a one-step drying-mediated process [1]. These 10nm thin membranes can stretch over holes up to 100 microns in diameter and are supported by a substrate only along their outer edge, thereby freely suspending of the order of 100 million close-packed particles [2]. Previous work has focused on quasi-static mechanical properties [1-3]. Here we present the first investigation of the full dynamic response of freely suspended nanoparticle membranes, utilizing a high frequency laser interferometer with picometer sensitivity. This instrument allows us to rapidly measure the dynamical properties of freestanding nanoparticle monolayers for the first time including resonant frequencies, quality factors, and images of different modes.

[3] Pongsakorn Kanjanaboos et al., “Strain Patterning and Direct Measurement of Poisson’s Ratio in Nanoparticle Monolayer Sheets,” Nano Letters 11, 2567-2571 (2011).

12:27PM Q17.00005 Metamaterial Based Terahertz Detector, ANDREW STRIKWERDA, Boston University, HU TAO, Tufts University, EMIL KADLEC, Sandia National Laboratories, KEBIN FAN, Boston University, WILLIE PADILLA, Boston College, RICHARD AVERITT, Boston University, ERIC SHANER, Sandia National Laboratories, XIN ZHANG, Boston University — We have designed, fabricated, and characterized metamaterial enhanced bimaterial cantilever pixels for far-infrared detection. Local heating due to absorption from split ring resonators (SRRs) incorporated directly onto the cantilever pixels leads to mechanical deflection which is readily detected with visible light. Highly responsive pixels have been fabricated for detection at 95 GHz and 693 GHz, demonstrating the frequency agility of our technique, and their subwavelength nature enables their use as a focal plane array (FPA) to image near the diffraction limit. We have obtained single pixel responsivities as high as 16,500 V/W and noise equivalent powers of 10-8 W/Hz^{1/2} with these first-generation devices, which were achieved at room temperature and pressure. Consequently, MMs hold great promise for facilitating the development of a “versatile” THz detector which can a) strongly absorb THz radiation; b) operate at room temperature; c) function as a multi-pixel array for imaging applications; and d) be lightweight and low cost.

12:39PM Q17.00006 Experimental observation of strong microwave-induced force in parallel-plate metallic cavity, Z. MARCET, University of Florida, Hong Kong University of Science and Technology, Z.H. HANG, S.B. WANG, C.T. CHAN, H.B. CHAN, Hong Kong University of Science and Technology — It has long been known that light induced forces have an impact on matter. These forces, albeit small, have found various applications in physics, chemistry and biology. The magnitude of this induced force is directly related to the momentum carried by light. With a much longer wavelength than visible light, microwave radiation is commonly regarded to having negligible mechanical impact on macroscopic objects. Here we present the first experimental demonstration of a strong repulsive force induced by incident microwave radiation in parallel centimeter-sized metallic plates. We found that the microwave radiation induced force can be significantly stronger than the usual photon pressure exerted by the incident beam when the cavity is excited at resonance, as strong electromagnetic energy is trapped inside the cavity walls. There is good agreement between experimental measurement and calculations using a boundary element method and the Maxwell stress tensor formalism. Our effort may bring new applications of microwave manipulations in the microwave and metamaterial communities.

12:51PM Q17.00007 Geometrical structure, multifractal spectra and localized optical modes of aperiodic Vogel spirals. , JACOB TREVINO, Division of Materials Science and Engineering, Boston University, SENG FATT LIEW, HESSO NOH, HUI CAO¹, Department of Applied Physics, Yale University, LUCA DAL NEGRO², Department of Electrical and Computer Engineering, Boston University — We present a numerical study of the structural properties, photonic density of states and bandedge modes of Vogel spiral arrays of dielectric cylinders in air. Specifically, we systematically investigate different types of Vogel spirals obtained by the modulation of the divergence angle parameter above and below the golden angle value (≈ 137.507 degrees). We found that these arrays exhibit large fluctuations in the distribution of neighboring particles characterized by multifractal singularity spectra and pair correlation functions that can be tuned between amorphous and random structures. We also show that the rich structural complexity of Vogel spirals results in a multifractal photonic mode density and isotropic bandedge modes with distinctive spatial localization character. Vogel spiral structures offer the opportunity to create a novel photonic devices that leverage radially localized and isotropic bandedge modes to enhance light-matter coupling, such as optical sensors, light sources, concentrators, and broadband optical couplers.

1:03PM Q17.00008 Geometrically Structured Dynamic Shadowing Lithography: Structural Growth and Control¹, SHENGRONG YE, AARON ROUTZAHN², R. LLOYD CARROLL³, Department of Chemistry, West Virginia University — Sphere lithography (SL), or nanosphere lithography (NSL), stands out as a versatile technique capable of producing 2D periodic micro- and nanostructures using colloidal crystal as deposition mask. Many of the fundamental aspects of the features produced by SL have been extensively investigated, including the optical, magnetic, electronic, and catalytic behaviors with emphasis toward applications in biosensing, ultrasensitive spectroscopy, and nanodevice fabrication. Previous work has primarily focused on 2D patterning, however, with little attention paid to vertical growth of the SL features. In this work, we will demonstrate the 3D structural evolution of metal dot arrays by SL-based geometrically structured dynamic shadowing lithography (GSDSL). The resulting structure is highly dependent on the nature of the metal that is used as evaporative source. We will specifically focus on the difference in the grain size of several typical metals and illustrate the ability in control of the structural growth through experiment and modeling. We believe that knowledge of the detailed geometry will enable us to understand further information on the physical and chemical properties of the SL substrates.

1:15PM Q17.00009 Omni-directional active pillar arrays for emission extraction and on-chip generation of optical vortices at $1.55\mu\text{m}$, NATE LAWRENCE, Department Electrical Engineering, Boston University, JACOB TREVINO, Division of Material Science, Boston University, LUCA DAL NEGRO, Department Electrical Engineering, Boston University — We engineer deterministic aperiodic structures (DAS) for omni-directional light extraction, emission profile shaping and direct orbital angular momentum generation from Si-based light emitting devices operating at telecom wavelengths. Omni-directional diffraction is achieved through the use of structures with circularly symmetric Fourier space and is well suited for extracting light from devices, such as LEDs or lasers. To exploit the unique light scattering properties of these structures we have fabricated active pillar arrays of Erbium (Er) doped Silicon-Rich Nitride (SRN) using electron beam lithography (EBL) and reactive ion etching (RIE) while varying geometry to optimize extraction enhancement around $1.55\mu\text{m}$. We find that aperiodic spiral arrays with continuous circular Fourier space give over 10 times extraction enhancement and outperform Archimedean lattices, which are the standard structures commonly utilized for omni-directional extraction. Additionally we directly image the real and reciprocal space of the emitted radiation at $1.55\mu\text{m}$ and demonstrate direct generation of optical vortices with well-defined values of orbital momentum. These results offer the opportunity to engineer novel optical devices that leverage the control of structured light on optical chips, such as novel laser sources, broadband optical couplers and concentrators.

1:27PM Q17.00010 Synthesis and Structural Characterization of Orthorhombic Vanadium Oxide Nanorods, L.M. GARCIA, E. CHAVIRA, Instituto de Investigacion en Materiales, UNAM, Mexico, DF 04510, P. SANTIAGO-JACINTO, L. RENDON, Instituto de Fisica, UNAM, Mexico, DF 04510, E.E. MARINERO, Hitachi San Jose Research Center, 3404 Yerba Buena Road, San Jose, CA 95135, A. TEJADA, E. FREGOSO-ISRAEL, C. FLORES, Instituto de Investigacion en Materiales, UNAM, Mexico, DF 04510 — Nanorod structures for Li storage are of interest for rechargeable battery applications. Vanadium pentoxide is a promising battery cathode material and in this work we report on the synthesis of V_2O_5 orthorhombic single crystal and polycrystalline nanorods by the sol-gel polymerizing acryl amide method via ethylenediamine tetra acetic acid EDTA assisted hydrothermal process. In order to determine the thermodynamic stability of nanostructured polymorphs vanadates, heat treatments were performed from 450°C to 500°C with annealing times ranging from 48 to 72 h. The morphologies and structures of the nanorods were characterized by XRD, SEM and HRTEM. Thermo Gravimetric Analysis (TGA) was employed to monitor reaction mass losses during the course of the synthesis. Nanorod diameters ranging from 50 to 150 nm were observed. The lengths and diameter of the rods depended on the conditions of the preparation, such as concentration, and reaction time.

1:39PM Q17.00011 Nonlinear metamaterials through enhanced impact ionization in GaAs at terahertz frequencies, KEBIN FAN, Boston Univeristy, HAROLD HWANG, Massachusetts Institute of Technology, MENGKUN LIU, ANDREW STRIKWERDA, JINGDI ZHANG, AARON STERNBACH, XIN ZHANG, Boston Univeristy, KEITH NELSON, Massachusetts Institute of Technology, RICHARD AVERITT, Boston Univeristy, BOSTON UNIVERISTY TEAM, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM — We report the experimental observation of a nonlinear response in metamaterial split ring resonators on semi-insulating GaAs at terahertz frequencies. Using metamaterials with narrow gaps (down to $1\mu\text{m}$), a local in-gap THz field of 3.5 MV/cm was achieved with a field enhancement of ~ 20 on resonance. With increasing THz electric field the metamaterial resonance is gradually quenched as the capacitive gap is shorted due to a large change in the local conductivity in the gap. This indicates an increase of the local carrier density by ten orders of magnitude resulting from impact ionization. Hybrid metamaterials with intense local electric fields not only have the potential to serve as a new tool to study nonequilibrium transport phenomena in materials, but also provide a new way to explore nonlinear metamaterials at terahertz frequencies.

1:51PM Q17.00012 Mode nonorthogonality in nonhermitian PT-symmetric optical resonators, GWANGSU YOO, H.-S. SIM, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea, HENNING SCHOMERUS, Department of Physics, Lancaster University, Lancaster LA1 4YB, United Kingdom, QUANTUM ELECTRON TRANSPORT THEORY GROUP TEAM, CENTRE FOR NANOSCALE DYNAMICS AND MATHEMATICAL MODELLING COLLABORATION — PT -symmetric optical resonators combine absorbing regions with active, amplifying regions. The latter are the source of radiation generated via spontaneous and stimulated emission, which embodies quantum noise and can result in lasing. We calculate the frequency-resolved output radiation intensity of such systems and relate it to a suitable measure of excess noise and mode nonorthogonality. The lineshape differs depending on whether the emission lines are isolated (as for weakly amplifying, almost hermitian systems) or overlapping (as for the almost degenerate resonances in the vicinity of exceptional points associated to spontaneous PT -symmetry breaking). The calculations are carried out in the scattering input-output formalism, and are illustrated for a quasi one-dimensional resonator set-up.

2:03PM Q17.00013 Elastic metamaterials and effective medium theory, YING WU, Division of Mathematical and Computer Sciences and Engineering, King Abdullah University of Science and Technology, YUN LAI, Department of Physics, Soochow University, China, PING SHENG, Department of Physics and William Mong Institute of Nano Science and Technology, Hong Kong University of Science and Technology, ZHAO-QING ZHANG, Department of Physics and William Mong Institute of Nano Science and Technology, Hong Kong University of Science and Technology — The unusual properties of a metamaterial are induced by the resonance in its building blocks. We derived an effective medium theory for elastic metamaterials in two dimensions, which is capable of predicting the wave propagation behavior inside the metamaterial near resonances of the building-block. It reveals the connection between resonances and negativities in effective medium parameters. Based on the EMT, we design two types of elastic metamaterials consisting of different resonance structures in their building blocks that can exhibit multiple negative dispersion bands with special characteristics. One is able to produce negative shear modulus and negative mass density simultaneously over a frequency regime, and the other is super-anisotropic. All of these unusual properties are demonstrated by multiple-scattering theory or finite element simulations.

Session Q18 DMP: Focus Session: Interfaces in Complex Oxides - Electronic, Magnetic and Optical Properties 252B

11:15AM Q18.00001 First principles insights into electronic, magnetic, and dynamic effects at and across oxide interfaces¹, SOHRAB ISMAIL-BEIGI, Yale University — The recent experimental capacity to create high quality epitaxial oxide/oxide interfaces has opened new avenues for research and provides examples of novel materials properties that emerge at the interfaces and in some cases only exist at the interfaces. Furthermore, a coherent, high-quality interface allows degrees of freedom in the two materials to be coupled to each other across the interface thereby creating artificial multi-functional materials systems. Ab initio theoretical approaches can provide key understanding of these complex systems as they can directly describe the interfacial chemical and structural effects on the electronic properties without assumptions or empirical parameters that are derived from bulk properties. Here, we will provide recent examples from our work showing how the presence and structure of the interface can modify the electronic, magnetic, or transport properties. For example, at a ferroelectric/manganite interface we see how the ferroelectric polarization couples to and strongly modifies the magnetism in the manganite. Another example involves dynamic coupling across an insulator/manganite interface where structural fluctuations in the insulator modify the conductivity in the manganite. In part, we will be focusing on the types of structural distortions present at such interfaces, how they are different from or non-existent in the bulk, and which type of distortions create uniquely interfacial phenomena.

11:51AM Q18.00002 Digital Layered-Manganites: Madelung Energy Effects on Atomic Structure and Properties, B. NELSON-CHEESEMAN, MSD, Argonne Natl Lab, J. RONDINELLI, MSE, Drexell Univ, H. ZHOU, APS, Argonne Natl Lab, M. NIKIFOROV, CNM, Argonne Natl Lab, E. BARNES, MSE, Penn State Univ, A. SHAH, MRL, Univ of IL Urbana-Champaign, S. BADER, MSD/CNM, Argonne Natl Lab, V. GOPALAN, MSE, Penn State Univ, A. BHATTACHARYA, MSD/CNM, Argonne Natl Lab — The atomic monolayer control of molecular beam epitaxy allows one to explore non-equilibrium dopant-cation configurations in correlated oxide thin films, enabling new electronic phases and magnetic properties to emerge. We report the effects of digital A-site cation doping on electronic phase stability and competition in perovskite-derived manganites. In such digitally synthesized films, Madelung energy constraints are expected to play a primary role in minimizing local Coulomb forces. We correlate changes in the electrical and magnetic properties of the ordered manganites and the resulting crystal structures (Mn-O bond lengths and O-Mn-O bond angles) to the compositionally equivalent control films, i.e. those with randomly distributed A-site dopant-cations. DFT calculations predict that these different layering patterns produce different local and extended crystallographic distortions, including a potential multiferroicity induced by a hitherto unknown mechanism. Synchrotron surface X-ray diffraction measurements in combination with COherent Bragg Rod Analysis at the Advanced Photon Source is used to investigate the resulting atomic structure of the different layering variants, while Second Harmonic Generation and Piezoforce Microscopy investigate the ferroelectric properties.

12:03PM Q18.00003 Reduced dimensionality and pseudogap formation in $(\text{LaMnO}_3)_{2n}(\text{SrMnO}_3)_n$ superlattices, ERIC MONKMAN, CAROLINA ADAMO, DANIEL SHAI, JOHN HARTE, DAWEI SHEN, BULAT BURGANOVA, DARRELL SCHLOM, KYLE SHEN, Cornell University — $(\text{LaMnO}_3)_{2n}(\text{SrMnO}_3)_n$ superlattices, composed of the antiferromagnetic insulators LaMnO_3 (LMO) and SrMnO_3 (SMO), are ferromagnetic and metallic for $n < 3$. By increasing the separation between LMO/SMO interfaces for $n \geq 3$, the system goes through a transition from a metallic to insulating ground state whose origin remains unresolved. We present ARPES measurements of $\text{LMO}_{2n}\text{SMO}_n$ superlattices grown by MBE. The electronic structure of states near the Fermi level is similar to the random alloy $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$ for small n , but as n is increased we observe the formation of a more 2D state with a preferential occupation of $x^2 - y^2$ orbitals. As the system passes into the insulating state at $n = 3$, a pseudogap forms at the Fermi level: charge carriers are suppressed over a scale of hundreds of meV but without substantial changes to the overall bandstructure. This pseudogap begins to fill as the temperature is increased, but a large suppression in spectral weight at the Fermi level remains at room temperature. Our observations indicate that the insulating state for large- n superlattices is related to strong many-body effects within this system, enhanced by the reduced dimensionality of an interfacial two-dimensional electron liquid.

12:15PM Q18.00004 Cross-sectional Scanning Tunneling Microscopy (XSTM) Investigation on $(\text{SrMnO}_3)_n/(\text{LaMnO}_3)_n$ Heterostructures¹, WEI-CHENG KUO, Department of Electrophysics, National Chiao Tung University, HsinChu 30100, Taiwan, YING-HAO CHU, Department of Materials Science and Engineering, National Chiao Tung University, HsinChu 30100, Taiwan, TZENG-MING UEN, JENH-YIH JUANG, Department of Electrophysics, National Chiao Tung University, HsinChu 30100, Taiwan — Recent advances in obtaining heterostructures between dissimilar transition-metal oxides with atomically sharp interfaces have revealed emerging exotic electronic and magnetic phases in the vicinity of the interface, which are qualitatively different from the parent compounds. In this study, we have grown $(\text{SrMnO}_3)_n/(\text{LaMnO}_3)_n$ heterostructure superlattice, with n being varied from 2 to 8, by laser MBE system with the assistance of the reflection high-energy electron diffraction (RHEED) intensity oscillations on (001) SrTiO_3 single-crystal substrates. The variation of the density of states across the vicinity of the SrMnO_3 - LaMnO_3 interfaces were investigated by scanning tunneling microscopy (STM) to reveal the spatial modulation of the electronic properties arising from formation of the two-dimensional electron system at the interfaces. The effects of the layer number, n , on this electronically-induced contrast, which is generally ascribed to result from the differences in the energy band gaps, carrier concentrations, as well as electron affinities between SrMnO_3 and LaMnO_3 , will be discussed.

12:27PM Q18.00005 Magnetoelectric coupling at the interface of manganite thin films grown on strontium titanate, MATTHEW MARSHALL, FRED WALKER, CHARLES AHN, CRISP, Dept. of Applied Physics, Yale University, New Haven, CT, 06520 — Oxide heterostructures of $\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3/\text{La}_{0.8}\text{Sr}_{0.2}\text{MnO}_3/\text{SrTiO}_3$ (PZT/LSMO/STO) have been shown to undergo a large charge-driven magnetoelectric coupling. Switching the polarization state of the ferroelectric PZT layer induces a spin reconstruction in the top atomic layer of the magnetic LSMO layer, changing from ferromagnetic to antiferromagnetic ordering [1]. In this work, the LSMO layer is several unit cells thick. In order to enhance this magnetic switching effect, we have reduced the thickness of the active LSMO layer, replacing part of the LSMO film with LaMnO_3 (LMO), a bulk antiferromagnetic insulator. To carry out this approach, we use oxide molecular beam epitaxy (MBE) to control the composition of thin films of LMO and LSMO/LMO heterostructures on $\text{SrTiO}_3(001)$ with atomic layer precision. Heterostructures grown in this way show a large deviation from the expected behavior for a simple combination of the individual components. We compare measurements of the magnetization for epitaxial LMO on SrTiO_3 and heterostructures of LSMO/LMO grown on SrTiO_3 . Using this approach, one can optimize the properties of the ferromagnetic layer and improve the magnetoelectric switching properties of the PZT/LSMO/STO system. [1] CAF Vaz, et al. Phys. Rev. Lett. 104, 127202 (2010); doi:10.1103/PhysRevLett.104.127202

12:39PM Q18.00006 Density-functional Study of Suppressed Magnetism at $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$ Interfaces¹, JUN HE, Vanderbilt University, ALBINA BORISEVICH, SERGEI KALININ, STEPHEN PENNY-COOK, Oak Ridge National Laboratory, SOKRATES PANTELIDES, Vanderbilt University — The experimentally observed magnetism suppression at interfaces of $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ has attracted increasing attention. Here we report density-functional calculations for the interface systems of $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$. Two interface models are employed to isolate and identify different effects coming from epitaxial strain, symmetry-breaking, charge redistribution, and oxygen vacancy segregation. We found that the strain effect from SrTiO_3 substrate is not significant enough to cause magnetism suppression at the interface. Although the symmetry is broken at interfaces, this effect leads only to a local ground state and does not cause the observed suppression either. The choice of interface termination does have an effect: moderate magnetism suppression is found for SrO/MnO_2 termination. Finally, we considered the effect of oxygen vacancy segregation at the interface. In the scenarios we have tested, oxygen vacancies do not suppress the interfacial magnetism. Thus, a complicated mechanism is needed to explain the suppressed magnetism at $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$ interfaces.

12:51PM Q18.00007 Optical Measurements on Magnetoelectric LSMO/PZT Bilayers, DISHENG CHEN, SRINIVAS POLISETTY, EVAN WOLFE, JINLING ZHOU, MIKEL HOLCOMB, West Virginia University, THANH TRA VU, JAN-CHI YANG, YING-HAO CHU, National Chiao Tung University — Fairly weak magnetoelectric coupling observed in the only single phase material (BeFeO_3) exhibiting magnetism and ferroelectricity at room temperature has pushed scientists to consider alternative systems. Multilayers prove promising theoretically and experimentally, however, most modern techniques are blind to the interfacial mechanisms causing the coupling. Without a full understanding of the physical mechanism for these effects, significant improvements in the design and multiple potential applications of magnetoelectric coupling will be difficult to achieve. Optical measurements including second harmonic generation are crucial tools to solve this problem, as they provide complementary insight into the magnetic/ferroelectric properties and resulting carrier dynamics. For example, angular dependence SHG of magnetic LaSrMnO_3 and ferroelectric PbZrTiO_3 bilayers indicates the symmetry and magnetization as we vary thicknesses of the magnetic and ferroelectric layers and its implication to magnetoelectric coupling.

1:03PM Q18.00008 Mn valences in $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3$ Heterostructures, JINLING ZHOU, SRINIVAS POLISETTY, EVAN WOLFE, CHARLES FRYE, DISHENG CHEN, MIKEL HOLCOMB, West Virginia University, CATHERINE JENKINS, ANDREAS SCHOLL, Lawrence Berkeley National Lab, YING-HAO CHU, National Chiao Tung University — Magnetoelectric (ME) coupling—the electrical control of magnetic properties or vice versa—has promising applications in computer memory and logic, magnetic sensing and energy scavenging. Understanding the coupling mechanisms in a variety of magnetoelectric material systems is an important step as it will allow us to design better magnetoelectric systems. Our group studies the interfacial properties of the known magnetoelectric system of a ferromagnetic $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3$ (LSMO) and a ferroelectric $\text{PbZr}_{0.2}\text{Ti}_{0.8}\text{O}_3$ (PZT). Through photoemission electron microscopy imaging, ME coupling was confirmed at the interface. X-ray absorption spectroscopy of Mn was taken across wedged samples of varying ferroelectric and ferromagnetic thicknesses. Here, we will show the changes of Mn valences at different thicknesses of LSMO and PZT, which helps to understand ME coupling and impact of thickness on the ME properties.

1:15PM Q18.00009 Magnetic coupling at vertical perovskite-spinel epitaxial interface, QING HE, ELKE ARENHOLZ, Advanced Light Source, JAN-CHI YANG, YING-HAO CHU, National Chiao Tung University — Interfaces in complex oxides have been the focus of scientists because of their intriguing and unique properties that cannot be found in bulk. Vertical nanostructure is one of the most interesting heterostructure that has been studied for interface phenomena due to its high interface-volume ratio. In this study, $(\text{La,Ca})\text{MnO}_3$ (LCMO) (perovskite, matrix) / CoFe_2O_4 (CFO) (spinel, pillars, 50-200 nm in size) vertical nanostructure has been taken as model system to investigate the interface magnetic coupling with X-ray absorption spectroscopy and photoemission electron microscopy (PEEM), taking the advantages of their element sensitivity and spatial resolution. Matrix and pillars were studied separated with the photon energy set to different absorption edges. The magnetic order and valence states as well as site occupancy in CFO pillars were characterized by XMCD measurements at Co and Fe L-edges with the application of external magnetic fields. In order to investigate the exchange coupling at the interface, we combined this XMCD study with angular dependent XMLD measurements at Fe and Mn L-edges, which give us the information of orbital order in LCMO, while CFO pillars are magnetized in different directions. Similarly, XMCD studies at the Mn L-edges provide detailed insights into the magnetic order of the LCMO matrix, the Mn valence state and elucidate the impact of the CFO pillars. In addition, PEEM measurement provides spatially resolved XMCD/XMLD images that give more insight of the magnetic coupling at the matrix-pillar interface.

1:27PM Q18.00010 Transport Properties of Films of Prussian Blue Analogues and Manganites¹, P.A. QUINTERO, D.M. GRANT, E.S. KNOWLES, M.F. DUMONT, J.H. JEEN, A. BISWAS, M.W. MEISEL, Dept. Phys. and NHMFL, Univ. Florida, D.R. TALHAM, Dept. Chem., Univ. Florida — The CoFe Prussian blue analogue (PBA) is a coordination polymer, $\text{A}_x\text{Co}_k[\text{Fe}(\text{CN})_6]$ ($\text{A} = \text{K}, \text{Rb}, \text{Cs}$), that exhibits a photoinduced charge transfer.² The resulting changes in the magnetization and in the lattice parameter have been used to successfully apply stress on other pressure-sensitive materials, achieving photocontrol of the magnetic response.³ The metal-to-insulator transition (MIT) is a prominent feature of the manganites, whose transition temperature can be tuned by applying various stimuli such as pressure or magnetic field.⁴ By coupling a layer of PBA over a thin film of manganite, the temperature for the MIT can be altered by the light-induced changes in the CoFe PBA.

1:39PM Q18.00011 Enhanced magnetoresistivity of modulation-doped manganite superlattices

, P.V. WADEKAR, Q.Y. CHEN¹, H.J. HUNAG, S.W. YEH, C.F. CHANG, L.W. TU, H. CHOU, N.J. HO, National Sun-Yat Sen University, Kaohsiung, Taiwan, O. LOZANO, D. WIJESUNDERA, W.K. CHU, Texas Center for Superconductivity, University of Houston, TX, USA — Modulation-doped epitaxial superlattices of $\text{La}_{1-x}\text{Ca}_x\text{MnO}_3$ and $\text{La}_{1-y}\text{Ca}_y\text{MnO}_3$ layers alternating with $x=1/3$ and $y=1/2$ on (001) LaAlO_3 substrates have been grown by magnetron sputtering. The magnetoresistivity (MR) has been greatly enhanced over a wide temperature range in comparison with the parent compounds. The MR is -50% at 0.5 Tesla and -90% at 4 Tesla. At low temperatures, a quantum interference effect (QIE) was observed, as manifested by a resistivity minimum considered to be incurred by the 3D e-e interactions. The modulation-doping approach is an enabling strategy to boost the sensitivity of colossal magnetoresistive oxides in response to an applied magnetic field.

¹Corresponding author, also with Texas Center for Superconductivity, University of Houston, TX, USA

1:51PM Q18.00012 Induced magnetism at complex oxide interfaces

, JACOBO SANTAMARIA, J. TORNOS, F.A. CUELLAR, J. GARCIA-BARRIOCANAL, Z. SEFRIQUI, A. RIVERA, C. LEON, GPMC. Depto. Fisica Aplicada III. U. Complutense. 28040 Madrid, M. BIBES, A. BARTHÉLÉMY, Unite Mixte de Physique CNRS/Thales, Campus de Polytechnique, 1, Avenue A. Fresnel, 91767 Palaiseau and Université Paris-Sud, 91045 Orsay, France, M.R. FITZSIMMONS, Los Alamos National Laboratory, Los Alamos NM 87545 USA, Y.H. LIU, S.G.E. TE VELTHUIS, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA, M. VARELA, S.J. PENNYCOOK, Condensed Matter Sciences Division Oak Ridge National Laboratory, Tennessee 37831-6031, USA, N.M. NEMES, M. GARCIA HERNANDEZ, Instituto de Ciencia de Materiales de Madrid (ICMM-CSIC). 28049 Cantoblanco. Madrid — Modified bonding at complex oxide interfaces may be at the bottom of the appearance of interesting novel behaviours not appearing in the bulk constituents. The possibility of tailoring the electronic structure of interfaces has driven an important effort towards the design of interfaces with specific functionalities. We have examined novel interfacial magnetic states originating at the modification of the orbital occupancy resulting from the modified bonding at the interface. We discuss the effect of these low dimensional magnetic states in determining the macroscopic magnetic response and in tailoring specific functionalities of heterostructures.

2:03PM Q18.00013 Photostriction-Magnetostriction Coupled Epitaxial Nanostructures

, YING-HAO CHU, National Chiao Tung University — Extensive research on complex oxide thin films and heterostructures suggest new possibilities to create and design devices with tantalizing functionalities by taking the advantages of the interplay between lattice, charge, orbital, and spin degrees of freedom. Recently, the self-assemble vertical nanostructures have drawn considerable attentions due to the strong coupling mediated by high interface-to-volume ratio to tailor the properties of oxide nanostructures. However, most studies have been stressing on the controllability of heterostructures through external electric or magnetic fields. In this study, we have synthesized SrRuO_3 (SRO)- CoFe_2O_4 (CFO) nanostructures to introduce light as other external control parameter, where the light-controlled properties are enabled by ultrafast photostriction of SRO and the magnetostriction of CFO. Through a combination of ultrafast-optics, magnetic force microscopy, and soft X-ray absorption spectroscopy, the coupling between SRO and CFO is clearly revealed. When illuminating CFO-SRO nanostructures, SRO matrix inflates its volume via expanding its c-axis; the elongated SRO matrix relaxes the out-of-plane compressive strain in CFO pillars effectively reduces the magnetic anisotropy thereof; the reduce magnetic anisotropy resets the preferred magnetization direction of CFO pillars; after removing the illumination, the magnetic anisotropy is re-installed and CFO pillars choose to reverse their magnetization. Our study paves a way to ultrafast optical-coupled functionalities.

Session Q19 FHP: Invited Session: The Scientific Legacy of Edward Purcell (1912-2012) 253AB

11:15AM Q19.00001 Purcell and NMR

, NICOLAAS BLOEMBERGEN, College of Optical Sciences, University of Arizona — In 1946 and 1947 the author carried out research at Harvard University under the guidance of Professor Edward M. Purcell. The results were communicated in a frequently cited paper, often referred to as BPP, after the authors Bloembergen, Purcell and Pound. The same material appeared in my 1948 Ph. D. Leiden thesis “Nuclear Magnetic Relaxation.” Some personal interactions with Ed Purcell and Bob Pound in these early and in later years at Harvard will be recounted.

11:51AM Q19.00002 Purcell and the Development of Radioastronomy

, DOC EWEN, Special Projects Team, LLC — “Join me for a ride on an electron, as we fly through electric and magnetic fields.” With those words, Ed Purcell began a course in Electromagnetic Theory. I had a front row seat. Ken Bainbridge recommended I take the course and get to know Ed. Ed’s wisdom and lucidity of thought soon gave the course, and Ed, a special place in my learning experience. I did not take notes in class. I was in awe at Ed’s ability to present the subject with such clarity and simplicity. Ed’s broad scope of interests and ability to present simple solutions to complex issues quickly led to my identification of Ed as the supreme mentor on any and all subjects. While working with Norman Ramsey to obtain an external beam from the Harvard Cyclotron, I consulted with Ed on the subject of available options. He suggested I scatter the beam off a target that could be remotely positioned, and catch it in a tunnel shielded from the magnetic field of the Cyclotron. When I had a problem with implementation I would, “Ask Ed.” During a visit to the Lab by Fermi, he commented on the simplicity of the solution. He was not surprised to learn that Purcell provided critical guidance. When I suggested Meteorology as a subject for my Oral Test, Purcell said it was not a science and I should pick another subject. I argued it was a science. Ed asked that I loan him some books on the subject and the Oral would be in two weeks. When I walked into the room for the Oral, I noticed that Ed had invited all seven authors of the books I had loaned to him. A simple Purcell answer to a problem. When I asked about his recommendations concerning doctorate dissertation topics, he said the selection must be based on my interests not his. I provided a brief summary: Mathematics, Quantum Mechanics, Meteorology, and Astronomy. Within two weeks, Ed proposed I look into the Hydrogen Line. After a joint review of the papers by Van de Hulst and Shklovski we concluded that: van de Hulst had clearly shown the line was undetectable, Shklovski had claimed the line was detectable, however, there was an error in his calculations. We noted, however, that the topic fit my interests. Purcell had a simple solution. I would proceed with a “negative thesis,” the goal to measure the level of non-detectability. As with all other joint ventures, Ed was always there when I needed help. His guidance was always simple and embarrassingly obvious. For my doctorate oral exam, Ed invited Van de Hulst as the only other participant. Purcell began by asking if I had any questions. I asked Van de Hulst why the line was detectable. Purcell then announced that I had my doctorate and could leave at any time, while he and Van de Hulst worked on the answer to my question. Many of us became terribly alone on March 7, 1997, when we learned we could no longer “Ask Ed.”

12:27PM Q19.00003 On small things in water moving around: Purcell’s contributions to biology

, HOWARD BERG, Departments of Molecular & Cellular Biology and of Physics, Harvard University — I went to see Purcell after finishing my course work for the Ph.D. (1961) to ask whether I might join his group. “But I don’t have any graduate students,” he said. “Why is that?” I asked. “I can’t think of anything to do,” he replied. That was a wipe out. After I had finished my Ph.D. with Ramsey on the hydrogen maser (1964), Ed and I came up with an idea that led to work on sedimentation field-flow fractionation (PNAS 1967). We had hoped this method would be useful for biology, but problems of adsorption of proteins to surfaces stood in the way. Then I moved over to the biology department and got interested in the motile behavior of bacteria (1968). Here was a subject that I thought Ed would really enjoy. There were wonderful movies made by Norbert Pfennig of experiments done by Theodor Engelmann in the 1880’s. We found a 16-mm projector and looked at these movies on Ed’s office wall. Ed’s first comment proved seminal, “How can such a small cell swim in a straight line?” We thought about how cells count molecules in their environment and wrote “Physics of chemoreception,” (*Biophys. J.*, 1977). In the meantime, Ed gave a memorable lecture at Viki Weisskopf’s retirement symposium, his classic “Life at low Reynolds number” (*Am. J. Phys.* 1977). Ed really wanted to understand what it would be like to swim like a bacterium! He wasn’t very interested in what the literature had to say about such a problem, he wanted to think it through for himself. My role was straight man. I very much enjoyed the ride.

1:03PM Q19.00004 Purcell's Work Helping the Government, RICHARD GARWIN, IBM Fellow Emeritus at IBM T.J. Watson Research Center, Yorktown Hts, NY 10598 — I worked closely with Ed Purcell from 1956 through 1975 or so, largely through our joint membership on and consulting with the President's Science Advisory Committee (PSAC) and working with the "Land Panel" on reconnaissance satellites. Purcell's work with the government had begun long before, with his 5-year service at the MIT Radiation Laboratory, and his advisory role had included, in particular, important work of the Technological Capabilities Panel (TCP) of the predecessor to PSAC. I will try to capture the flavor of Ed's contributions and the context of the times in which he was involved. His style and impact are well characterized by this quote from the book of Eisenhower's Science Advisor and PSAC Chair, James R. Killian, "When Eisenhower was later to speak in memorable tribute of 'my scientists' he was surely recalling among others this quiet, modest, lucid man. Robert Kreidler [one of Killian's staff], in an interview I had with him in preparing for this memoir spoke almost with awe of his [Purcell's] impact on PSAC, 'Ed Purcell did not speak often,' he said, 'but when he did there would be enormous silence in the room, because everybody knew that whatever he said was going to be worth listening to with careful attention.'" I give some examples why it was so worthwhile listening to Ed Purcell.

1:39PM Q19.00005 Purcell the Teacher: In and Out of the Classroom, JOHN RIGDEN, Washington University in St. Louis — As a high school student Edward Purcell read articles by K.K. Darrow from his series, "Advances in Contemporary Physics." Many years later, Purcell, referring to those articles, said they remind us "that great teaching does not require a classroom..." Many of Purcell's choices were motivated by his devotion to teaching: the undergraduate courses he preferred to teach at Harvard, the textbooks and pedagogical papers he wrote, and the professional activities he engaged in. He delighted in explaining complex phenomena in simple ways — a mark of a great teacher.

Wednesday, February 29, 2012 11:15AM - 2:15PM — Session Q20 FIAP: Invited Session: Robust Energy Storage with Engineered Si 253C

11:15AM Q20.00001 Silicon Nanowire Anodes: Materials and Composites, CANDACE CHAN, Arizona State University — Silicon nanowires (SiNWs) have the potential to perform as anodes for lithium-ion batteries with a much higher energy density than graphite. Previously, we have shown that reversible capacities $>3,000$ mAh/g can be obtained by using an electrode geometry consisting of SiNWs grown on metallic current collector substrates using the CVD-based vapor-liquid-solid (VLS) method. These electrodes consisted of SiNWs directly attached and vertically oriented off of the current collector. SiNWs can be synthesized in large quantities using the supercritical-fluid-solid (SFLS) method. Slurries were prepared composed of silicon nanowires synthesized using the SFLS method mixed with amorphous carbon or carbon anotubes and binder and coated onto Cu foil. Recent results regarding the cycling behavior of the SiNWs using different experimental conditions will be presented. The performance of these composite electrodes will also be compared with our previous work using the VLS SiNWs to determine how the electrode architecture affects the electrochemical performance.

11:51AM Q20.00002 Strain-tolerant High Capacity Silicon Anodes via Directed Lithium Ion Transport for High Energy Density Lithium-ion Batteries, JASON GOLDMAN, University of Illinois at Urbana Champaign — Energy storage is an essential component of modern technology, with applications including public infrastructure, transportation systems, and consumer electronics. Lithium-ion batteries are the preeminent form of energy storage when high energy / moderate power densities are required. Improvements to lithium-ion battery energy / power density through the adoption of silicon anodes—with approximately an order of magnitude greater gravimetric capacity than traditional carbon-based anodes—have been limited by $\sim 300\%$ strains during electrochemical lithium insertion which result in short operational lifetimes. In two different systems we demonstrated improvements to silicon-based anode performance via directed lithium ion transport. The first system demonstrated a crystallographic-dependent anisotropic electrochemical lithium insertion in single-crystalline silicon anode microstructures. Exploiting this anisotropy, we highlight model silicon anode architectures that limit the maximum strain during electrochemical lithium insertion. This self-strain-limiting is a result of selecting a specific microstructure design such that during lithiation the anisotropic evolution of strain, above a given threshold, blocks further lithium intercalation. Exemplary design rules have achieved self-strain-limited charging capacities ranging from 677 mAhg $^{-1}$ to 2833 mAhg $^{-1}$. A second system with variably encapsulated silicon-based anodes demonstrated greater than 98% of their initial capacity after 130+ cycles. This anode also can operate stably at high energy/power densities. A lithium-ion battery with this anode was able to continuously (dis)charge in 10 minutes, corresponding to a power / energy density of ~ 1460 W/kg and ~ 243 Wh/kg—up to 780% greater power density and 220% higher energy density than conventional lithium-ion batteries. Anodes were also demonstrated with areal capacities of 12.7 mAh/cm ^{2} , two orders of magnitude greater than traditional thin-film silicon anodes.

In collaboration with Michael W. Cason and Ralph G. Nuzzo.

12:27PM Q20.00003 Understanding the Degradation of Silicon Electrodes for Lithium-Ion Batteries Using Acoustic Emission and Fracture Mechanics¹, CLAUD DANIEL, Oak Ridge National Laboratory and University of Tennessee — Silicon is a promising anode material for lithium-ion battery application due to its high specific capacity, low cost, and abundance. However, when silicon is lithiated at room temperature, it can undergo a volume expansion in excess of 280%, which leads to an extensive fracturing. This is thought to be a primary cause of the rapid decay in cell capacity routinely observed. We have developed a special cell design which allows us to monitor acoustic emissions stemming from mechanical events in the cell and allow for detailed structural analysis using X-ray diffraction with an internal standard. The combined result from acoustic emissions and X-ray diffraction allow for a first of its kind detailed look at how silicon anodes degrade and together with presented theories of fracture mechanics enable a material engineering approach to optimize its long term behavior. In collaboration with Kevin Rhodes and Sergiy Kalnaus.

Parts of this research were performed at the High Temperature Materials Laboratory, a national user facility sponsored by the same office.

¹This research at Oak Ridge National Laboratory, managed by U.T. Battelle, LLC, for the U.S. Department of Energy under contract DE-AC05-00OR22725 was sponsored by the Vehicle Technologies program for the Office of Energy Efficiency and Renewable Energy.

1:03PM Q20.00004 Reversible Cycling of Silicon and Silicon Alloys¹, MARK OBROVAC, Dalhousie University

— Lithium ion batteries typically use a graphite negative electrode. Silicon can store more lithium than any other element and has long been considered as an attractive replacement for graphite. The theoretical lithium storage capacity of silicon is nearly ten times higher than graphite volumetrically and three times higher gravimetrically. The equilibrium Si-Li binary system is well known. Completely new phase behaviors are observed at room temperature. This includes the formation of a new phase, Li₁₅Si₄, which is the highest lithium containing phase at room temperature [1]. The formation of Li₁₅Si₄ is accompanied by a 280 percent volume expansion of silicon. During de-alloying this phase contracts, forming amorphous silicon. The volume expansion of alloys can cause intra-particle fracture and inter-particle disconnection; leading to loss of cycle life. To overcome issues with volume expansion requires a detailed knowledge of Li-Si phase behavior, careful design of the composition and nanostructure of the alloy and the microstructure of the negative electrode [2]. In this presentation the phase behavior of the Li-Si system will be described. Using this knowledge alone, strategies can be developed so that silicon can be reversibly cycled in a battery hundreds of times. Further increases in energy density and efficiency can be gained by alloying silicon with other elements, while controlling microstructure [2]. Coupled with negative electrode design strategies, practical negative electrodes for lithium ion cells can be developed based on bulk materials, with significant energy density improvement over conventional electrodes.

¹Reversible Cycling of Silicon and Silicon Alloys

1:39PM Q20.00005 Pair Distribution Function Analysis and Solid State NMR Studies of Silicon Electrodes for Lithium Ion Batteries: Understanding the (De)lithiation Mechanisms, BARIS KEY, Argonne National Laboratory

— The crystalline-to-amorphous phase transition that occurs on electrochemical Li insertion into crystalline Si, during the first discharge, hinders attempts to link the structure with electrochemical performance. We apply a combination of local structure probes, in situ and ex situ ⁷Li nuclear magnetic resonance (NMR) studies, and pair distribution function (PDF) analysis of X-ray data to investigate the changes in short-range order that occur during the initial charge and discharge cycles. The distinct electrochemical profiles observed subsequent to the first discharge have been shown to be associated with the formation of distinct amorphous lithiated silicide structures. The first process seen on the second discharge is associated with the lithiation of the amorphous Si, forming small clusters. These clusters are broken in the second process to form isolated silicon anions. The (de)lithiation model helps explain the hysteresis and the steps in the electrochemical profile observed during the lithiation and delithiation of silicon. At deep discharge states a highly reactive lithium excess Li₁₅Si₄ phase is detected by in situ NMR which undergoes a self-discharge process in electrolyte.

Session Q21 DCMP: Novel Superconductivity in New and Low Dimensional Materials 254A

11:15AM Q21.00001 Superconductivity in ThCoC₂¹, TED GRANT, University of California Irvine, ANTONIO J.S.

MACHADO, EEL-USP Brazil, ZACHARY FISK, University of California Irvine — We report bulk superconductivity in the metallic carbide compound ThCoC₂. This compound crystallizes in the orthorhombic CeNiC₂ prototype structure, a non-centrosymmetric system. Despite the presence of Cobalt and the lack of inversion symmetry, we find bulk superconductivity with a critical temperature of T_c = 2.6 K. Details of the superconducting state with specific heat, magnetization, and resistivity measurements will be presented. This study was made possible by the generous support of AFOSR MURI "Search for New Superconductors for Energy and Power Applications."

¹Supported by AFOSR-MURI

11:27AM Q21.00002 Superconductivity in ScGa₃ and LuGa₃¹, ETERI SVANIDZE, EMILIA MOROSAN, Physics and Astronomy Department, Rice University

— We are reporting low-temperature superconductivity in single crystals of ScGa₃ and LuGa₃. While the latter compound had been listed as a superconductor before, superconductivity in the former compound had never been observed, and characterization of the low-temperature state was lacking in both compounds. By measurements of magnetization, specific heat and resistivity, we show that RGa₃ (R = Sc and Lu) are conventional BCS superconductors with T_c around 2.3 K and the upper critical field less than 240 Oe. The experimental results agree with band structure calculation estimate of the critical temperature.

¹NSF DMR 0847681

11:39AM Q21.00003 Physical properties of single crystalline SrSn₄ and BaSn₅ superconductors¹

, XIAO LIN, SERGEY BUD'KO, Department of Physics and Astronomy, Iowa State University and Ames Laboratory, GERMAN SAMOLYUK, Materials Science & Technology Division, Oak Ridge National Laboratory, MILTON TORIKACHVILI, Department of Physics, San Diego State University, PAUL CANFIELD, Department of Physics and Astronomy, Iowa State University and Ames Laboratory — We present the growths and detailed thermodynamic and transport measurements on single crystals of the recently discovered binary intermetallic superconductors, SrSn₄ and BaSn₅. Their superconducting transition temperatures T_c are found to be 4.8 K and 4.4 K respectively. Both materials are strongly-coupled, possibly multi-band superconductors. Hydrostatic pressure causes a decrease in the superconducting transition temperature at the rate of ≈ -0.068 K/kbar for SrSn₄, and ≈ -0.053 K/kbar for BaSn₅. Band structure and upper superconducting critical field anisotropy of SrSn₄ suggest complex, multi-sheet Fermi surface formed by four bands. De Hass-van Alphen oscillations are observed in BaSn₅, which indicates a more complex topology of Fermi surface.

¹Work was supported by AFOSR-MURI grant FA9550-09-1-0603; the DMSE, Office of Basic Energy Sciences, US DOE contract # DE-AC02-07CH 11358; and NSF grant DMR-0805335.

11:51AM Q21.00004 Synthesis, Structure, Physical Properties of several Zirconium Chalcogenides, XIYU ZHU, BING LV, LIANGZI DENG, FENG YAN WEI, YANYI SUN, YUYI XUE, PAUL CHING-WU CHU, Texas Center for Superconductivity, University of Houston, Houston TX 77204-5002, USA

— Compounds of KxZr₂Se₆, RbxZr₂Se₆ and ZrTe_{1.3}As_{0.7} have been fabricated by high temperature solid state synthesis technique. All these compounds have the same space group Immm. They can be generally considered as the compounds derived from ZrSe₃ and ZrTe₃, which accommodate the quasi 2D type structure composed by (Zr₂Se₂)(Se₄) and (Zr₂Te₂)(Te₄) layers. KxZr₂Se₆ and RbxZr₂Se₆ could be considered as the anionic layers [(Zr₂Se₂)(Se₄)]^{x-} intercalated with alkali cations. One the other hand, ZrTe_{1.3}As_{0.7} isn't a layered compound. The compound has the same structure with NbPS, with disordered As and Te occupying the P sites. This structure could be considered as a derivative structure of ZrTe₃ with the retained (Zr₂Te₂) layers interspersed with linear (Te_{0.3}As_{0.7}) chains. We also measured the magnetic and transport properties of these samples. We shall present and discuss their interesting structural and physical properties.

12:03PM Q21.00005 Superconductivity in Pd, Ir, and Pt chalcogenide, YOON SEOK OH, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, JUNJIE YANG, Laboratory for Pohang Emergent materials, Postech, Korea, Y.J. CHOI, A. HOGAN, Y. HORIBE, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University — Large spin-orbit coupling in materials with heavy chalcogens can result in unique quantum states or functional properties such as topological insulator, giant thermoelectric power, and superconductivity. When materials contain heavy cations in addition to heavy chalcogens, spin-orbit coupling can be further enhanced. For these reasons, we have studied the superconductivity of Pd, Ir, and Pt tellurides and selenides. In the exploration of these chalcogenides, we have focused on the competition between superconductivity and charge density wave that is associated with superlattice reflections.

12:15PM Q21.00006 Elementary excitations and elusive superconductivity in palladium hydride – *ab initio* perspective. I. Paramagnons, P. BUCZEK, MPI Halle, Germany, V. BORISOV, MLU Halle-Wittenberg, Germany, C. BERSIER, MPI Halle, Germany, S. OSTANIN, MLU Halle-Wittenberg, Germany, L. SANDRATSKII, MPI Halle, Germany, J.B. STAUNTON, University of Warwick, United Kingdom, E.K.U. GROSS, MPI Halle, Germany, I. MERTIG, MLU Halle-Wittenberg, Germany, A. ERNST, MPI Halle, Germany — Motivated by a experimental reports on possible high temperature superconductivity in palladium hydride [Tripodi *et al.*, *Physica C* **388-389**, 571 (2003)], we present a first principle study of spin fluctuations, electron-phonon coupling and critical temperature in PdH_x , $0 \leq x \leq 1$. A prerequisite for any qualitative study of exchange-enhanced materials is the knowledge of spin flip fluctuation spectrum. It is generally believed [Berk & Schrieffer, *Phys. Rev. Lett.*, **17**, 433 (1966)] that the ferromagnetic-like paramagnons of Pd are destructive for the conventional, i.e. *s*-wave, superconductivity. We describe them using linear response time dependent density functional theory, recently implemented to study complex metals [Buczek *et al.*, *Phys. Rev. Lett.* **105**, 097205 (2010)]. We find that hydrogenation suppresses the intense spin fluctuations of pure Pd, driving it away from a magnetic critical point. Under the assumption of *s*-wave pairing, this could lead to the formation of the superconducting state. The *ab-initio* estimated electron-phonon coupling is strong enough to support superconductivity. Please look for the complementary contribution of Christophe Bersier.

12:27PM Q21.00007 Elementary excitations and elusive superconductivity in palladium hydride – *ab initio* perspective. II. Phonons, CHRISTOPHE BERSIER, PAWEŁ BUCZEK, MPI Halle, Germany, VLADISLAV BORISOV, SERGEY OSTANIN, MLU, Halle-Wittenberg, Germany, LEONID SANDRATSKII, MPI Halle, Germany, JULIE B. STAUNTON, University of Warwick, United Kingdom, E.K.U. GROSS, MPI Halle, Germany, I. MERTIG, MLU, Halle-Wittenberg, Germany, ARTHUR ERNST, MPI Halle, Germany — Motivated by a experimental reports on possible high temperature superconductivity in palladium hydride [Tripodi *et al.*, *Physica C* **388-389**, 571 (2003)], we present a first principle study of spin fluctuations, electron-phonon coupling and critical temperature (T_c) in PdH_x , $0 < x < 1$. Our results described in terms of (i) electronic structure, (ii) phonon density of states and (iii) Eliashberg function show that the hydrogenation of Pd clearly enhance the electron-phonon coupling in this material. Assuming phonons to be the driving force for superconductivity, fcc Pd features a vanishingly small T_c , while for the stoichiometric $x = 1$ PdH the resulting T_c is around 10K in agreement with experiment. It is generally believed [Berk & Schrieffer, *Phys. Rev. Lett.*, **17**, 433 (1966)] that intense spin-&flip fluctuations of Pd are destructive for the conventional, i.e. *s*-wave, superconductivity. However, the H doping leads to a drastic reduction of spin-flip scattering. Please look for complementary presentation of Paweł Buczek.

12:39PM Q21.00008 Structural and Electronic properties of the 2D Superconductor CuS covellite with 113-valent Copper, IGOR MAZIN, Naval Research Laboratory — Hexagonal CuS has recently been reported to superconduct at 40 K. At the same time, earlier experiments had found superconductivity at 1.5 K. Some authors reported local magnetic moments in this compound, while others observe pure Pauli paramagnetism. It exhibits a rather unusual for a good metal symmetry-lowering transition at 55 K of unknown origin. Even the Cu valency in CuS has been debated, with suggested ionic models such as $(\text{Cu}^{+1})_3(\text{S}_2^{-2})(\text{S}^{-1})$ and $(\text{Cu}^{+1})_3(\text{S}_2^{-1})(\text{S}^{-2})$, as well as noninteger valencies. To gain more insight, we've performed DFT calculations and found that the actual valency of Cu is $4/3$ (2), so that the Cu d band is not sufficiently ionized in the ideal compound to provide enough proximity to Mott dielectric for either local moments or unconventional superconductivity. On the other hand, the reason that Cu is not divalent here is that some sulfurs form covalent S_2 molecules with the effective S_2^{-2} valency. If some of these covalent S-S bonds are broken, local moments *can* form, and in that case superexchange in the hexagonal lattice can induce *f*-wave pairing. Finally, regarding the structural transition, it is well reproduced in DFT calculations. Possible microscopic origin of this transition will be discussed in the talk.

12:51PM Q21.00009 Moving Beyond Quantum Mechanics in Search for a Generalized Theory of Superconductivity, GODFREY AKPOJOTOR, Delta State University, ALEXANDER ANIMALU, International Centre for Basic Research — Though there are infinite number of theories currently in the literature in the search for a generalized theory of superconductivity (SC), there may be three dominating mechanisms for the Cooper pair formation (CPF) and their emergent theories of SC. Two of these mechanisms, electron-phonon interactions and electron-electron correlations which are based on the quantum theory axiom of action-at-a distance, may be only an approximation of the third mechanism which is contact interaction of the wavepackets of the two electrons forming the Cooper pair as envisaged in hadronic mechanics to be responsible for natural bonding of elements. The application of this hydronic –type interaction to the superconducting cuprates, iron based compounds and heavy fermions leads to interesting results. It is therefore suggested that the future of the search for the theory of SC may be considered from this natural possible bonding that at short distances, the CPF is by a nonlinear, nonlocal and nonhamiltonian strong hadronic-type interactions due to deep wave-overlapping of spinning particles leading to Hulthen potential that is attractive between two electrons in singlet couplings while at large distances the CPF is by superexchange interaction which is purely a quantum mechanical affairs.

1:03PM Q21.00010 Material Specific Design for Room Temperature Superconductivity¹, O-PAUL ISIKAKU-IRONKWE², The Center for Superconductivity Technologies, (TCST), Department of Physics, Michael Okpara University of Agriculture, Umudiike, (MOUUAU), Nigeria, UKO OFE, TCST @ MOUUAU, CHIJOKE ORIAKU, DAN ASIEGBU, TCST@MOUUAU, EMEKA OGUZI, TCST and Department of Chemistry, FUTU, Owerri, Nigeria — The transition temperature, T_c , of superconductors has been increased sevenfold from 23K in Nb_3Ge to 164K in Hg-1223. A further two-fold increase would get us to above room temperature superconductivity. Studying high temperature superconductors (HTSCs), we have developed a formula that expresses T_c in terms of electronegativity, valence electrons, N_v , atomic number, Z , formula mass and a coupling constant, K_o . We observe an increasing linear relationship between T_c and K_o . K_o also correlates with formula mass and atomic number and the number of atoms in the compound. By our formula, Hg-1223 has $K_o = 70$. We propose, using our design algorithm, that room temperature superconductivity may be realized in a system with $K_o = 160$; electronegativity = 2.5, $N_v/\text{Sqrt } Z = 0.8$. We proceed to show combinations of oxides and elements that will yield the required parameters for synthesizing reproducible room temperature superconductivity.

1:15PM Q21.00011 Thermopower and Resistivity in the Spin Density Wave- Metal co-existence regime of (TMTSF)2PF6, ARJUN NARAYANAN, PAUL CHAIKIN, Department of Physics, New York University — The organic conductor (TMTSF)2PF6 is studied in the pressure regime where it is believed to exhibit co-existence between Metallic and Spin Density Wave domains. In this pressure regime, an anisotropy in the superconductivity transition - seen previously in resistivity data on separate samples in different experimental runs - is here reproduced using both resistivity and thermopower as probes, on three slices of the same crystal measured simultaneously. The simultaneous use of these two measurements along the a, b and c axes, enables us to extract complementary information about the remarkable anisotropy in the superconducting transition and may shed light on the possibly inhomogeneous ground states in the co-existence regime of (TMTSF)2PF6.

1:27PM Q21.00012 Non-analytical Angular Dependence of the Upper Critical Magnetic Field in a Quasi-One-Dimensional Superconductor¹, OTAR SEPPER, ANDREI LEBED, University of Arizona — We have derived the so-called gap equation, which determines the upper critical magnetic field, perpendicular to conducting chains of a quasi-one-dimensional superconductor. By analyzing this equation at zero temperature, we have found that the calculated angular dependence of the upper critical magnetic field is qualitatively different than that in the so-called effective mass model. In particular, our theory predicts a non-analytical angular dependence of the upper critical magnetic field, $H_{c2}(0) - H_{c2}(\alpha) \sim \alpha^{3/2}$, when magnetic field is close to one of the crystallographic axes and makes an angle α with the axis. We discuss possible experiments on the superconductor (DMET)2I3 to discover this non-analytical dependence.

¹This work was supported by the NSF under Grant No. DMR-1104512

1:39PM Q21.00013 Hidden Reentrant and Larkin-Ovchinnikov-Fulde-Ferrell Superconducting Phases in a Magnetic Field in (TMTSF)2ClO4¹, ANDREI LEBED, Department of Physics, University of Arizona — We solve a long-standing problem about a theoretical description of the upper critical magnetic field, parallel to conducting layers and perpendicular to conducting chains, in (TMTSF)2ClO4 superconductor. In particular, we explain why the experimental upper critical field, $H_{c2}^b = 6\text{T}$, is higher than both the quasi-classical upper critical field and Clogston paramagnetic limit. We show that this property is due to the coexistence of the hidden Reentrant and Larkin-Ovchinnikov-Fulde-Ferrell phases in a magnetic field in a form of three plane waves with non-zero momentums of the Cooper pairs. Our results are in good qualitative and quantitative agreement with the recent experimental measurements of H_{c2}^b and support a singlet d-wave-like scenario of superconductivity in (TMTSF)2ClO4.

¹This work was supported by the NSF thru Grant # DMR-1104512.

1:51PM Q21.00014 ¹H NMR Spin-Lattice Relaxation Study of κ -(ET)2Cu[N(CN)2]Br, J.C. GEZO, TAK-KEI LUI, R.W. GIANNETTA, C.P. SLICHTER, Loomis Laboratory of Physics, University of Illinois at Urbana-Champaign, IL 61801, J.A. SCHLEUTER, Material Sciences Division, Argonne National Laboratory, Argonne IL 60439 — The discovery of an anomalous Nernst signal in the organic superconductor κ -(ET)2Cu[N(CN)2]Br suggests the presence of magnetic flux vortices above T_c ^[1]. Previous studies below the transition temperature have shown that the additional fluctuating field created by vortices dramatically increases the ¹H NMR spin-lattice relaxation rate^[2]. We revisit ¹H spin-lattice relaxation in κ -(ET)2Cu[N(CN)2]Br and provide new evidence of inhomogeneous behavior both above and below T_c . ^[1]M. S. Nam et al, Nature 449, 584-587 (2007) ^[2]H. Mayaffre et al, Phys. Rev. Lett. 76, 4951-4954 (1996) Work at UIUC supported by NSF DMR 10-05708 and the Center for Emergent Superconductivity, USDOE Award No. DE-AC0298CH1088. Work at Argonne supported by UChicago Argonne, LLC, Operator of Argonne National Laboratory, DOE Contract No. DE-AC02-06CH11357.

2:03PM Q21.00015 ¹³C NMR Study of Slow Motions in κ -(ET)2Cu[N(CN)2]Br¹, TAK-KEI LUI, JOSEPH C. GEZO, RUSSELL W. GIANNETTA, CHARLES P. SLICHTER, University of Illinois at Urbana-Champaign, IL 61801, JOHN A. SCHLEUTER, Material Sciences Division, Argonne National Laboratory, Argonne, IL 60439 — Like the high- T_c cuprates, the 2D organic superconductor κ -(ET)2Cu[N(CN)2]Br ($T_c = 11.9\text{ K}$) exhibits a pseudo-gapped phase above the superconducting transition, as indicated by the ¹³C spin-lattice relaxation rate ($1/T_1T$) peak at about 50 K. While ¹³C NMR has been used extensively to probe the pseudo-gapped regime, T_1 is only sensitive to fast motions in the MHz scale (Larmor frequency), and T_2 remains relatively constant in the pseudo-gapped regime. Neither T_1 nor T_2 give us any clue about any possible slow motions. We report measurements using the stimulated echo pulse sequence² which is capable of providing more detailed information on possible slow motions in the pseudo-gapped regime.

Wednesday, February 29, 2012 11:15AM - 2:15PM –
Session Q22 DMP DCOMP: Focus Session: Fe-based Superconductivity - Doped and Undoped BaFe2As2 254B

11:15AM Q22.00001 Nature of phase transitions in the parent and lightly electron doped BaFe2As2 compounds¹, MIN GYU KIM, R.M. FERNANDES, A. KREYSSIG, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA, J.W. KIM, Advanced Photon Source, ANL, Argonne, IL, A. THALER, S.L. BUD'KO, P.C. CANFIELD, R.J. MCQUEENEY, J. SCHMALIAN, A.I. GOLDMAN, Ames Laboratory, Dept. of Physics and Astronomy, Iowa State University, Ames, IA — We present a combined high-resolution x-ray diffraction and x-ray resonant magnetic scattering study of as-grown BaFe2As2. The structural and magnetic transitions must be described as a two-step process. The undoped BaFe2As2 parent compound manifests a second-order structural transition from the high-temperature paramagnetic tetragonal structure to a paramagnetic orthorhombic phase and a first-order antiferromagnetic transition from the paramagnetic orthorhombic phase to an antiferromagnetic orthorhombic phase at slightly lower temperature. As electrons are introduced by Co or Rh, the phase transitions evolve toward second-order transitions. Using these results, we provide an estimate of the position of a tricritical point in the phase diagram of Ba(Fe1-xCox)2As2.

¹The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, DMSE, contract DE-AC02-07CH11358.

11:27AM Q22.00002 Neutron powder diffraction studies on $\text{Ba}_{1-x}\text{A}_x\text{Fe}_2\text{As}_2$ ($\text{A}=\text{Na}, \text{K}$)¹, SEVDA AVCI, DUCK-YOUNG CHUNG, HELMUT CLAUS, STEPHAN ROSENKRANZ, RAY OSBORN, Argonne National Laboratory, OMAR CHMAISSEM, Northern Illinois University and Argonne National Laboratory, MERCOURI KANATZIDIS, Northwestern University and Argonne National Laboratory, EUGENE GORE-MYCHKIN, ISIS, Rutherford Appleton Laboratory, UK — In the so-called 122 iron pnictide superconductors, the SDW is suppressed and superconductivity can be induced by various means including charge doping, pressure, and isovalent substitution. Using neutron powder diffraction and SQUID magnetization measurements, we have investigated the effects of both potassium and sodium substitution on superconductivity, structural transformation and magnetic ordering in $\text{Ba}_{1-x}\text{A}_x\text{Fe}_2\text{As}_2$ ($\text{A}=\text{K}, \text{Na}$) producing detailed phase diagrams of both systems. We present a comparison of the similarities and differences in the various internal atomic and magnetic structural parameters as a function of temperature and composition of these two hole-doped systems.

¹This work is supported by U.S. Department of Energy Office of Science under contract No. DE-AC02-06CH11357.

11:39AM Q22.00003 Neutron diffraction study of the development of incommensurate magnetic order in $\text{Ba}(\text{Fe}_{1-x}\text{M}_x)\text{As}_2$ ($\text{M} = \text{Co}, \text{Ni}, \text{Cu}$)¹, R.J. MCQUEENEY, M.-G. KIM, D.K. PRATT, Ames Laboratory, Iowa State University, Ames, IA 50011, T.W. HEITMANN, The Missouri University Research Reactor, University of Missouri, Columbia, MO 65211, J. LAMSAL, S.N. KHAN, Y.B. LEE, G.S. TUCKER, A. THALER, S. RAN, S.L. BUD'KO, P.C. CANFIELD, D.D. JOHNSON, B.N. HARMON, A. KREYSSIG, A.I. GOLDMAN, Ames Laboratory, Iowa State University, Ames, IA 50011 — We employ neutron diffraction and electronic structure calculations using both virtual crystal and coherent potential approximations to investigate the conditions for incommensurate magnetism in several electron-doped compounds $\text{Ba}(\text{Fe}_{1-x}\text{M}_x)\text{As}_2$ with $\text{M} = \text{Co}, \text{Ni}, \text{Cu}$. Incommensurate order is observed for $\text{M} = \text{Co}$ and Ni with $x \approx 0.06$ and 0.03 , respectively. Assuming each Co (Ni) ion donates one (two) additional electrons, the appearance of incommensurate magnetism in the Co and Ni doped systems occurs at similar electron concentrations. For $\text{M} = \text{Cu}$, Cu should donate three electrons and one expects that incommensurate magnetism will appear at $x \approx 0.02$. However, we find that the magnetism remains commensurate until it disappears at $x \approx 0.05$. Thus, Cu doping behaves differently than either Co or Ni , as can be explained from the electronic structure.

¹The work at the Ames Laboratory was supported by US DOE, Office of Basic Energy Sciences, DMSE, contract DE-AC02-07CH11358.

11:51AM Q22.00004 Magnetic moment in single crystalline $\text{BaFe}_{2-x}\text{Zn}_x\text{As}_2$, YANFENG GUO, International Center for Materials Nanoarchitectonics (MANA), National Institute for Materials Science, XIA WANG, JUN LI, KAZUNARI YAMAURA, Superconducting Materials Centre, National Institute for Materials Science, EIJI TAKAYAMA-MUROMACHI, International Center for Materials Nanoarchitectonics (MANA), National Institute for Materials Science — Nature of the magnetism for iron-based superconductors (FeSCs) has been actively studied since the discovery of this new family of compounds in 2008, largely owing to its significance for interpreting the pairing mechanism. The approach through impurity substitution to shed light into this issue is always one of major ways. The substitution shows distinct responses to species of impurities, where partially replacement of Fe in parent FeSCs with a variety of d -metals like Co , Ni , Ru , Rh , Pd , Ir , and Pt generally results in superconductivity, while recent progress in Zn doped FeSCs gives rather contrary result, where Zn severely degenerates the T_C . Herein we show the magnetic and electrical studies on $\text{BaFe}_{2-x}\text{Zn}_x\text{As}_2$ single crystals. Nonmagnetic Zn doping progressively suppresses the SDW without resulting in superconductivity, while it alternatively develops the spin-glass state, possibly suggestive of local magnetic moment around the Fe sites induced by Zn . The characterizations by X-ray diffraction, magnetic and electrical transport properties, specific heat capacity, and Hall coefficient have been done and the results will be discussed in detail.

12:03PM Q22.00005 75As-NMR studies on $\text{Ba}(\text{Fe}_{1-x}\text{Ni}_x)_2\text{As}_2$ single crystals, JIANLIN LUO, XIAODONG ZHANG, GUOZHI FAN, XIUNIAN JING, Institute of Physics, Chinese Academy of Sciences, CHENGLIN ZHANG, Department of Physics and Astronomy, The University of Tennessee — 75As nuclear magnetic resonance (NMR) were measured for $\text{Ba}(\text{Fe}_{1-x}\text{Ni}_x)_2\text{As}_2$ single crystals with $x = 0.05$ and $x = 0.1$ under 0 GPa and 1.5 GPa, respectively. For the optimal doped sample with $x = 0.05$, the superconducting transition temperature T_C is strongly suppressed from 18 K to 5 K, while for the over-doped sample with $x = 0.1$, it is turned from the superconducting ground state to a disordered paramagnetic state under 1.5 GPa. Our experimental results show that the antiferromagnetic spin fluctuations are suppressed as well as T_C . The experimental results can be explained with the two-band model. As a result, the electronic band is downward shifted with increase of pressure and the electrons become the dominant carriers in the system.

12:15PM Q22.00006 Do Transition Metal Substitutions Dope Carriers in Iron Based Superconductors?¹, TOM BERLIJN, Brookhaven National Laboratory, CHAI-HUI LIN, Stony Brook University, WEI KU, Brookhaven National Laboratory — We investigate the currently debated issue concerning whether transition metal substitutions dope carriers in iron based superconductors. From first-principles calculations of the configuration-averaged spectral function [1,2] of BaFe_2As_2 with disordered Co/Zn substitutions of Fe , important doping effects are found beyond merely changing the carrier density. While the chemical potential shifts suggest doping of a large amount of carriers, a reduction of the coherent carrier density was found due to the loss of spectral weight. Therefore, none of the change in the Fermi surface, density of states, or charge distribution can be solely used for counting doped coherent carriers, let alone presenting the full effects of the disordered substitutions. Our study highlights the necessity of including disorder effects in the studies of doped materials in general. [1] W. Ku, T. Berlijn. and C.-C. Lee, Phys. Rev. Lett. 104, 216401 (2010) [2] T. Berlijn, D. Volja and W. Ku, Phys. Rev. Lett. 106, 077005 (2011)

¹Work supported by DOE DE-AC02-98CH10886 and DOE CMCSN

12:27PM Q22.00007 X-ray absorption spectroscopy study in the BaFe_2As_2 family, YOONYOUNG KOH, YEONGKWAN KIM, Yonsei university, WANLI YANG, Advanced Light Source, CHANGYOUNG KIM, Yonsei university — One of the representative Fe-based superconductor families, BaFe_2As_2 ($T_C \approx 38\text{K}$) is a semimetal with the same number of hole and electron carriers, and is in a spin density wave state below 139K. It has been reported that various types of “doped” BaFe_2As_2 systems can be obtained by substitution of Ba , Fe , and As atoms. However, an important issue has been recently raised regarding whether each type of substitution indeed induces effective charge doping or not. It is essential to clarify whether each type of substitution indeed induce an effective doping in BaFe_2As_2 system. To clarify the carrier doping issue, we performed high resolution X-ray absorption spectroscopy experiment on $\text{Ba}(\text{Fe}, \text{Co})_2\text{As}_2$, $\text{Ba}(\text{Fe}, \text{Ru})_2\text{As}_2$, $\text{BaFe}_2(\text{As}, \text{P})_2$ which are representative “doped” BaFe_2As_2 systems.

12:39PM Q22.00008 Competing Magnetic Phases in $\text{Ba}(\text{Fe}_{0.925}\text{Mn}_{0.075})_2\text{As}_2$ ¹, G.S. TUCKER, D.K. PRATT, M.G. KIM, S. RAN, A. THALER, Ames Laboratory and Department of Physics & Astronomy, Iowa State University, G.E. GRANROTH, K. MARTY, Oak Ridge National Laboratory, W. TIAN, J.L. ZARESTKY, S.L. BUD'KO, P.C. CANFIELD, A. KREYSSIG, A.I. GOLDMAN, R.J. MCQUEENEY, Ames Laboratory and Department of Physics & Astronomy, Iowa State University — Inelastic neutron scattering measurements on $\text{Ba}(\text{Fe}_{0.925}\text{Mn}_{0.075})_2\text{As}_2$ show broad, diffusive spin fluctuations at two different propagation vectors corresponding to stripe magnetic order and conventional Néel antiferromagnetic order. Below $T = 80\text{K}$ long-range stripe magnetic ordering occurs and sharp spin wave excitations appear at the stripe propagation vector while diffusive spin fluctuations remain at the Néel propagation vector. These results suggest that low concentrations of Mn dopants introduce a competing magnetic phase that may prevent the development of superconductivity in $\text{Ba}(\text{Fe}_{1-x}\text{Mn}_x)_2\text{As}_2$.

12:51PM Q22.00009 Infrared pseudogap in P- and Co-doped BaFe₂As₂ superconductors , S.J.

MOON, A.A. SCHAFFGANS, Department of Physics, University of California, San Diego, S. KASAHARA, Research Center for Low Temperature and Materials Science, Kyoto University, T. SHIBAUCHI, Department of Physics, Kyoto University, T. TERASHIMA, Research Center for Low Temperature and Materials Science, Kyoto University, Y. MATSUDA, Department of Physics, Kyoto University, M.A. TANATAR, R. PROZOROV, A. THALER, P.C. CANFIELD, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, A.S. SEFAT, D. MANDRUS, Materials Science and Technology Division, Oak Ridge National Laboratory, D.N. BASOV, Department of Physics, University of California, San Diego — We investigated the in-plane electronic response of P- and Co-doped BaFe₂As₂ compounds using infrared spectroscopy. We found hallmarks of the normal-state pseudogap in the optical spectra of the BaFe₂As₂ system, which are very similar with those of the cuprates. Based on the evolution of the electronic response with doping and across the superconducting transition, we suggest that the antiferromagnetic fluctuations can be a possible origin of the infrared pseudogap in the iron pnictides. We will also discuss implications of our results for the origin of the pseudogap in the cuprates.

1:03PM Q22.00010 Effects of disordered isovalent substitution in Fe-based superconductor¹

, LIMIN WANG, TOM BERLIJN, Brookhaven National Laboratory, YAN WANG, University of Florida, CHAI-HUI LIN, Stony Brook University, Brookhaven National Laboratory, P.J. HIRSCHFELD, University of Florida, WEI KU, Brookhaven National Laboratory, Stony Brook University — Using a recently developed first-principles method for disordered materials [1-2], we investigate the effect of isovalent substitution in Fe-based superconductors, BaFe₂(As_{1-x}P_x)₂, FeTe_{1-x}Se_x, and Ba(Fe_{1-x}Ru_x)₂As₂. For anion substitutions (the first two cases) effects of impurity scattering are found mostly in the anion bands. By contrast, the Ru substitution introduces much stronger scattering in the Fe bands. Surprisingly, in all the cases, the pockets near the chemical potential are the least affected, due to the low density of states near the chemical potential. Together, our results suggest an interesting scenario of enhancing superconductivity.

1:15PM Q22.00011 Electron Injection and “Oxygen Effect” in BaFe₂As₂: Mössbauer Studies

, AIRAT KHASANOV, University of North Carolina at Asheville, DING HU, XINGYE LU, HUIQIAN LUO, Institute of Physics, Academy of Sciences, Beijing, China, JIANYI JIANG, ERIC HELLSTROM, Florida State University, AMAR NATH, University of North Carolina at Asheville, MATERIALS RESEARCH LAB TEAM, HIGH FIELD LAB TEAM, BEIJING NATIONAL LABORATORY OF CONDENSED MATTER PHYSICS TEAM — It is widely believed that a few percent substitution of Co (with d7) or Ni (with d8) for Fe (with d6) in BaFe₂As₂ results in donation of electrons, killing of magnetism, and thereby induction of superconductivity. We are exploring the possibility of injecting electrons by physico-chemical techniques instead of substitutions. We have also discovered that traces of chemisorbed oxygen can change drastically the magnetic behavior in polycrystalline BaFe₂As₂ at low temperatures. BaFe₂As₂ exhibits considerable hysteresis behavior as well that of thermal history.

1:27PM Q22.00012 ABSTRACT MOVED TO Y22.00013 —

1:39PM Q22.00013 Effects of annealing on Ba(Fe_{1-x}Co_x)₂As₂ and Ba(Fe_{1-x-y}Co_xTM_y)₂As₂ (TM=Mn,Cr) single crystals¹ , ALEX THALER, SHENG RAN, Iowa State University/Ames Lab, ALFRED KRACHER, Retired, WARREN STRASZHEIM, JIA YAN, SERGEY BUD'KO, PAUL CANFIELD, Iowa State University/Ames Lab — Single crystals of Ba(Fe_{1-x-y}Co_xTM_y)₂As₂ (TM=Cr, Mn) have been grown and characterized by structural, magnetic and transport measurements, both in the as-grown state (quenched from ~ 1000° C) as well as after post-growth annealing. This phase space has many parameters and is rich and complex, with superconducting transition temperatures depending upon x and y, as well as annealing temperature and time. In this talk, we will present T-x and T-y, as well as T-time and T-T (for annealing) phase diagrams and discuss the implications for future research into these complex materials.

¹Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

1:51PM Q22.00014 Infrared conductivity of BaFe₂As₂ superconductors: Effects of in-plane and out-of-plane doping , R.P.S.M. LOBO, LPEM, ESPCI, CNRS, Paris, France, Y.M. DAI, B. XU, B. SHEN, H.H. WEN, X.G. QIU, IOP, Chinese Academy of Sciences, Beijing, China — We measured the *in-plane* optical conductivity of a nearly optimally doped (*T*_c = 39.1 K) single crystal of Ba_{0.6}K_{0.4}Fe₂As₂. Upon entering the superconducting state the optical conductivity vanishes below ~ 20 meV, indicating a fully gapped system. A model with two different isotropic gaps is required to describe the optical response of this material. The temperature dependence of the gaps indicate a strong interband interaction, but no impurity scattering induced pair breaking is present. This contrasts to the large residual conductivity observed in optimally doped Ba(Fe_{1-x}Co_x)₂As₂ and strongly supports an *s*_± gap symmetry for both compounds.

2:03PM Q22.00015 Ultrafast Probing of Antiferromagnetism and Dynamic Critical Behaviors in Iron Pnictide , TIANQI LI, AARON PATZ, SHENG RAN, SERGEY BUD'KO, PAUL CANFIELD, JIGANG WANG, Department of Physics and Astronomy and Ames Laboratory-USDOE, Iowa State University, DEPARTMENT OF PHYSICS AND ASTRONOMY AND AMES LABORATORY-USDOE, IOWA STATE UNIVERSITY COLLABORATION — Iron pnictide superconductors and their parent compounds exhibit superconductivity, antiferromagnetism, poor conductivity in undoped phase, structural instabilities, and additional peculiarities. Much of the complexity originates from strong interactions among the spin, charge, lattice degrees of freedom, where correlated excitations and self-organization among them occur and cause exotic cooperative behaviors. Time-resolved magneto-optical spectroscopy has been developed as a power tool to dynamically disentangle various degrees of freedoms by exploring their responses to fs photoexcitation. Using femtosecond optical and magneto-optical technique, we were able to measure and decoupling dynamics of AFM, structure and electronic excitations in parent BaFe₂As₂ and also underdoped sample (Co=4.7%). The technique demonstrated provides an extremely powerful tool to reveal fs dynamics and critical behaviors of various order parameters in the iron pnictide system.

Wednesday, February 29, 2012 11:15AM - 2:15PM —

Session Q23 DCMP: Superconductivity Theory III: Mainly Cuprates 255

11:15AM Q23.00001 Grand-canonical variational study for the Gutzwiller-projected BCS wave function , TING-KUO LEE, CHUNG-PIN CHOU, Institute of Physics, Academia Sinica, Nankang, Taipei 11529, Taiwan, FAN YANG, Department of Physics, Beijing Institute of Technology, Beijing PRC — We study the Gutzwiller-projected BCS wave function in the 2D extended t-J model using a variational Monte Carlo method. To take into account the effect of Gutzwiller projection, a fugacity factor proposed by Laughlin and Anderson has been included into the coherence factor of the BCS state. We show that the ground-state energy and excitation spectra calculated in the grand-canonical picture are essentially the same as previous results in the canonical scheme if the free energy is used for minimization. Except for La-214 materials, we find that the doping dependence of chemical potential is consistent with experimental findings on several cuprates. We have investigated the asymmetry of tunneling conductance observed by scanning tunneling spectroscopy becomes much stronger as decreasing doping. A very huge enhancement of phase fluctuation in the underdoped regime has been found.

11:27AM Q23.00002 Fluctuating Bond Model of cuprate superconductivity. , JENHAO HSIAO, NTHU, R.A. NISTOR, Columbia University, G.J. MARTYNA, D.M. NEWNS, C.C. TSUEI, IBM Watson Research Center — The fluctuating bond model(FBM), an empirical model based on a strong, local coupling of electrons to the square of the planar oxygen vibrator amplitudes, provides explanations of the d-wave pairing mechanism¹ and the pseudogap² of cuprate superconductivity. The d-wave pairing is mediated by the anharmonic phonon (planar oxygen vibrator) which is also responsible for the pseudogap when the C4 symmetry of the oxygen vibrator is broken. Here we present calculations of gap and T_c in a unitary framework involving pseudogap as a competing order parameter, with the help of ab initio simulations.

11:39AM Q23.00003 d-wave superconductivity from correlated hopping interactions determined by angle-resolved photoemission spectroscopy¹ , CHUMIN WANG, CESAR G. GALVAN, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico, LUIS A. PEREZ, Instituto de Fisica, Universidad Nacional Autonoma de Mexico — Starting from a generalized Hubbard model, in which correlated-hopping interactions are considered in addition to the on-site repulsive Coulomb one, we solve numerically two coupled integral equations [1] within the Bardeen-Cooper-Schrieffer formalism, in order to quantify the doping effects on the critical temperature (T_c), d-wave superconducting gap, and the electronic specific heat. Within the mean-field approximation, we have determined the single and correlated electron hopping parameters for $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$ compound by using angle-resolved photoemission spectroscopy (ARPES) data [2]. The resulting parametrized Hubbard model is able to explain the experimental T_c variation as a function of the doping level (x). In addition, the observed power-law behavior of the superconducting specific heat is reproduced by this correlated-hopping Hubbard model without adjustable parameters. [1] L.A. Pérez, J.S. Millán, C. Wang, *Int. J. Mod. Phys. B* **24**, 5229-5239 (2010). [2] T. Yoshida, *et al.*, *Phys. Rev. B* **74**, 224510 (2006).

11:51AM Q23.00004 Role of the charge reservoir layer in cuprate superconductors , THEODORE GEBALLE, SRINIVAS RAGHU, Stanford University — The high pressure measurements of Jorgensen *et al.*, which show that T_c increases as the apical oxygen distance from the CuO_2 plane decreases, is at odds with current theoretical predictions of T_c . Furthermore, the unusually close T_c (and similar NMR signatures) of Hg and TI based families of cuprates, in addition to the facts that their T_c is significantly higher than superconductors without charge reservoir layers (CRLs), suggest that CRLs play a significant role in determining T_c . Based on recent studies of S. Raghu *et al.* on the effects of longer ranged interactions on unconventional superconductivity, we discuss the possibility of the generic role that the CRLs may have in enhancing T_c by considering their role in screening short-range repulsive Coulomb interactions within the CuO_2 plane.

12:03PM Q23.00005 Phase separation instabilities and pairing modulations in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$, ARMEN KOCHARIAN, California State University, Los Angeles, CA 90032, KUN FANG, GAYANATH FERNANDO, KALUM PALANDAGE, University of Connecticut, Storrs, CT 06269, ALEXANDER BALATSKY, Theoretical Division, LANL, Los Alamos, NM 87545 — There is a growing evidence that the unconventional spatial inhomogeneities accompanied with the pairing of electrons, subsequent quantum phase transitions (QPTs), and condensation control coherent states in doped high- T_c cuprate superconductors, iron pnictide and telluride materials. We show that these superconducting states can be obtained from the phase separation instabilities near the quantum critical points. We examine electron coherent and incoherent pairing instabilities using our results on exact diagonalization in pyramidal and octahedron Hubbard-like clusters under variation of chemical potential (or doping), interaction strength, temperature and magnetic field. We also evaluate the dependence of the energy gap function in the vicinity of the sign change (nodes) as a function of position of the apical oxygen atom, due to vibration of apical atom and variation of inter-site coupling. The developed approach provides a simple microscopic explanation of (correlation) supermodulation of the coherent pairing gap observed recently in the scanning tunneling microscopy experiments at atomic scale in $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$.

12:15PM Q23.00006 Pairing Correlations in the two-layer attractive Hubbard Model , ALEKSANDER ZUJEV, PINAKI SENGUPTA, Nanyang Technological University, RICHARD SCALETTAR, UC Davis — Quantum Monte Carlo (QMC) is used to study pairing correlations in a two-layer Hubbard Model in which one layer is attractive ($U < 0$), and the other uncorrelated ($U = 0$). We provide a detailed characterization of how superconductivity in the $U < 0$ layer induces pairing in the $U = 0$ layer, as a function of the interlayer hopping, density, temperature, and on-site attraction strength in the $U < 0$ layer. QMC data are complemented by calculations within the Bogoliubov - de Gennes approximation.

12:27PM Q23.00007 Pair-Density-Wave Superconducting Order in Two-Leg Ladders , AKBAR JAEFARI, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We show, using bosonization and Renormalization Group methods, that Pair Density Wave (PDW) state happens in the system of two extended Hubbard-Heisenberg models on two leg ladders. Two different models are discussed in detail. In even legged ladder system we find that PDW state is the dominant instability for certain filling factors and some range of parameters. We show that phase diagram of the spin gap regime is composed of two dual phases: PDW and uniform Superconducting (SC) states. The phase transition between uniform SC and PDW in this model is shown to be in the Ising universality class. The idea has been generalized to the case of other commensurate fillings where we find higher order commensurate PDW states. Then we consider a two leg ladder system with nonzero flux Φ per plaquette. This system is commensurate for wide range of the electron fillings when $\Phi = \pi$. We show that commensurate PDW and incommensurate CDW are some of the phases present in the phase diagram of this model. We show how formation of PDW order in the ladder embodies the notion of intertwined orders.

12:39PM Q23.00008 Numerical Investigations of Spontaneous Orbital Currents in the Three-Orbital Hubbard Model¹, CHENG-CHIEN CHEN, ALEXANDER KEMPER, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory, CHUNJING JIA, Department of Applied Physics, Stanford University, RONNY THOMALE, Department of Physics, Stanford University, THOMAS DEVEREAUX, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory — Recent experiments show that the pseudogap regime of the cuprate superconductors could be characterized by a phase where the time-reversal symmetry is spontaneously broken but the translational symmetry remains intact. One possible but still highly disputed theory involves a circulating current looping around the Cu and O atoms. To address this issue, we perform large-scale exact diagonalization using a three-orbital Hubbard model on a Cu8O16 cluster. We find that the current-current correlations fall off quickly and show no signs of particular orbital current patterns. We also extend our calculations by adding explicitly a perturbative orbital current term into the Hamiltonian to study its experimental consequences. Using the magnetic moment measured in neutron scattering to constrain the strength of this perturbation, we compute the dichroic signals of various photon-spectroscopies to provide experimental benchmarks to test the existence of such a circulating current phase.

¹This work is supported by the U.S. DOE under contract number DE-AC02-76SF00515.

12:51PM Q23.00009 Momentum-Resolved d-wave Eliashberg Calculation Using The Spin Excitation Spectrum for LSCO Superconductors, SEUNG HWAN HONG, HAN-YONG CHOI, SungKyunKwan University — We solve the momentum resolved d-wave Eliashberg equation employing the magnetic excitation spectrum from the inelastic neutron scattering on the LSCO superconductors reported by Vignolle et al. [1]. The magnetic excitation spectrum exhibits 2 peaks: a sharp incommensurate peak at 18 meV at momentum $(\pi, \pi \pm \delta)$ and $(\pi \pm \delta, \pi)$, and another broad peak near 40~70 meV at momentum (π, π) . Above 70 meV, the magnetic excitation spectrum has a long tail that is shaped into a circle centered at (π, π) with δ' . The sign of the real part of the total self-energy $\Sigma(\vec{k}, \omega) + X(\vec{k}, \omega)$ is determined by the momentum position of the peaks of the magnetic excitation spectrum and bare dispersion $\xi(\vec{k})$. We will discuss the effects of the each component of the magnetic excitation spectrum on the self-energy $\Sigma(\vec{k}, \omega)$ the renormalization of the band dispersion $X(\vec{k}, \omega)$, the pairing function $\phi(\vec{k}, \omega)$, and the spectral function $A(\vec{k}, \omega)$.

1:03PM Q23.00010 Superconducting Instabilities in Electronic Liquid Crystal Phases, RODRIGO SOTO GARRIDO, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We discuss the superconducting instabilities in a two dimensional fermionic system in uniform electronic liquid crystal phases which cause the Fermi surfaces (FS) to become distorted. We study the case of fermions in a time-reversal broken nematic-like state with $l = 3$ in the charge channel, and the $l = 2$ state in the spin channel. We discuss the competition between singlet and triplet superconducting states with pair density wave states.

1:15PM Q23.00011 Odd-frequency triplet pairing in mixed-parity superconductors¹, MARIO CUOCO, PAOLA GENTILE, CANIO NOCE, ALFONSO ROMANO, GAETANO ANNUNZIATA, CNR-SPIN, I-84084 Fisciano (Salerno), Italy and Dipartimento di Fisica E. R. Caianiello, Università di Salerno I-84084 Fisciano (Salerno), Italy, JACOB LINDER, Department of Physics, Norwegian University of Science and Technology, N-7491 Trondheim, Norway — We show that mixed-parity superconductors may exhibit equal-spin pair correlations that are odd-in-time and can be tuned by means of an applied field. The direction and the amplitude of the pair correlator in the spin space turn out to be strongly dependent on the symmetry of the order parameter, and thus provide a tool to identify different types of singlet-triplet mixed configurations. We suggest that odd-in-time spin-polarized pair correlations can be generated without magnetic inhomogeneities in superconducting/ferromagnetic hybrids with non-centrosymmetric superconductor or when parity mixing is induced at the interface. Paola Gentile, Canio Noce, Alfonso Romano, Gaetano Annunziata, Jacob Linder, Mario Cuoco, arXiv:1109.4885

¹The research leading to these results has received funding from the FP7/2007-2013 under the grant agreement No. 264098 - MAMA

1:27PM Q23.00012 Common Fermi-liquid origin of T₂ resistivity and superconductivity in n-type SrTiO₃, DIRK VAN DER MAREL, DOOK VAN MECHELEN, University of Geneva, IGOR MAZIN, Naval Research Laboratory — SrTiO₃ is a semiconductor which, when doped with a low density of electrons, becomes a good conductor with relatively high mobility and strong temperature dependence of the electrical resistivity and the infrared optical conductivity. At low temperatures the material becomes superconducting with a maximum reported T_c below 1 K with a dome-shaped doping dependence of T_c, both in the 3D bulk material and at the 2D LaAlO₃/SrTiO₃ interface. The DC resistivity below 100 K has a T² temperature dependence. The quasiparticles are in the anti-adiabatic limit with respect to electron-phonon interaction, which renders the interaction mediated through phonons effectively non-retarded. We apply Fermi-liquid theory for the T² term in the resistivity, and combine this with expressions for T_c and with the Brinkman-Platzman-Rice (BPR) sum-rule to obtain Landau parameters of n-type SrTiO₃. These parameters are comparable to those of liquid ³He, indicating interesting parallels between these Fermi-liquids despite the differences between the composite fermions from which they are formed.

1:39PM Q23.00013 Time Reversal Invariant Topological Superconductor in Rashba System, SHO NAKOSAI, Dept. of Appl. Phys., Univ. of Tokyo, YUKIO TANAKA, Dept. of Appl. Phys., Nagoya Univ., NAOTO NAGAOSA, Dept. of Appl. Phys., Univ. of Tokyo, CMRG & CERG, ASI, RIKEN — Recently, topological superconductors (TSCs) have been intensively studied as one of the topologically nontrivial phases. TSCs are characterized by topological numbers classified by their symmetries and dimensions. In the previous proposals on TSCs in Rashba systems, Zeeman splitting is necessary and therefore time reversal symmetry (TRS) is broken. We consider instead a bilayer Rashba system, e.g., a two-interface system, where hybridization causes a band gap. As for the single layer case, it has been shown experimentally that at the interface of SrTiO₃/LaAlO₃, two dimensional electron gas with Rashba spin-orbit interaction and superconductivity is formed. We find that the hybridization in bilayer system leads to topological phase without breaking TRS. This system belongs to the class characterized by Z₂ index. We obtain the conditions for odd-parity pair potentials by analyzing relations between strength of interactions and types of pair potentials. TSCs are attained in the case when the system has an odd-parity pair potential and the Fermi energy lies in the hybridization gap. We analytically calculate a topological number in a bulk system, and explicitly confirm the bulk-edge correspondence by performing numerical calculation in a finite system with edges.

1:51PM Q23.00014 Pairing Theories in Very High Magnetic Fields: Effects of Condensed and Non-condensed Pairs, PETER SCHERPELZ, DAN WULIN, KATHRYN LEVIN, James Franck Institute and Department of Physics, University of Chicago, ATTIPAT RAJAGOPAL, Inspire Institute — In this talk we focus on the interplay of pseudogap effects with high magnetic fields. Our work is built on reformulating the Gor'kov equations in the non-linear regime into a Landau level basis. Here we explore two distinct fermionic pairing schemes associated with the Abrikosov lattice in real and reciprocal space. We show how both have antecedents in the literature and both can be extended to accommodate non-condensed pairs. With this formulation, we can calculate quantities including the local density of states and H_{c2} in this regime. Importantly, both pairing theories yield gapless excitations which should be relevant to cuprate magneto-oscillatory experiments. The additional implications for the high field diamagnetic susceptibility are discussed.

2:03PM Q23.00015 Quantum oscillations in vortex-liquids¹, SUMILAN BANERJEE, SHIZHONG ZHANG, MOHIT RANDERIA, Department of Physics, The Ohio State University, Columbus, OH 43210 — Motivated by observations of quantum oscillations in underdoped cuprates [1], we examine the electronic density of states (DOS) in a *vortex-liquid* state, where long-range phase coherence is destroyed by an external magnetic field H but the local pairing amplitude survives. We note that this regime is distinct from that studied in most of the recent theories, which have focused on either a Fermi liquid with a competing order parameter or on a d -wave vortex lattice. The cuprate experiments are very likely in a resistive vortex-liquid state. We generalize the s -wave analysis of Maki and Stephen [2] to d -wave pairing and examine various regimes of the chemical potential, gap and field. We find that the $(1/H)$ oscillations of the DOS at the chemical potential in a d -wave vortex-liquid are much more robust, i.e., have a reduced damping, compared to the s -wave case. We critically investigate the conventional wisdom relating the observed frequency to the area of an underlying Fermi surface. We also show that the oscillations in the DOS cross over to a $\sqrt{H}$ behavior in the low field limit, in agreement with the recent specific heat measurements. [1] L. Taillefer, J. Phys. Cond. Mat. **21**, 164212 (2009). [2] M. J. Stephen, Phys. Rev. B **45**, 5481 (1992).

¹Supported by DOE-BES grant DE-SC0005035

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q24 FIAP: Fractional Quantum Hall Effect II 256

11:15AM Q24.00001 Fractional Quantum Hall Effect of Rydberg-Polaritons, FABIAN GRUSDT, MICHAEL FLEISCHHAUER, Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, JOHANNES OTTERBACH, Physics Department, Harvard University, Cambridge, Massachusetts — Dark-state-polaritons (DSP) are bosonic quasiparticles arising in the interaction of light with 3-level atoms under conditions of electromagnetically induced transparency (EIT). They can be exposed to artificial magnetic fields, strong enough to enter the lowest Landau level regime [Otterbach et. al., Phys. Rev. Lett. **104** (2010)]. We take into account interactions between the DSPs via Rydberg dipole-dipole interactions and discuss the realization of the $\nu = 1/2$ -Laughlin state and its anyonic excitations (quasiholes) in such systems. The DSPs can be prepared in the correct total angular-momentum subspace by using orbital angular momentum light beams. A numerical and semi-analytical evaluation of the quasihole-gap is presented.

11:27AM Q24.00002 Compressible and incompressible phases in lattice fractional quantum Hall systems¹, SHUO YANG, KAI SUN, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD 20742 — We study lattice fractional quantum Hall (FQH) systems in the presence of local potential traps using the exact diagonalization technique. By implementing an array of local potential traps, we show that the system undergoes a series of phase transitions. As the strength of potential traps is increased, the FQH state turns into a compressible metallic state, and then into a topologically trivial insulator. We present the phase diagram as well as convincing numerical evidences which we use to identify these phases and phase transitions, including the energy spectrum, the fidelity metric, the Chern number, and the entanglement spectrum. In addition, we also compare the topological trivial insulator observed in our systems with Anderson insulators, which are expected in ordinary fractional quantum Hall systems in 2D electron gases in the presence of strong impurities.

¹This work is supported by DARPA-QuEST, Microsoft Q, and CNAM.

11:39AM Q24.00003 Tailoring Fabry-Perot Interferometers for Fragile Fractional Quantum Hall States¹, DOUGLAS MCCLURE, PATRICK GALLAGHER, CHARLES MARCUS, Harvard University, LOREN PFEIFFER, KEN WEST, Princeton University — Depending on the relevance of Coulomb interactions, electronic Fabry-Perot interferometers can exhibit two qualitatively different types of interference, each of which can shed light on the unique physics of quantum Hall systems. Long observed in the integer quantum Hall (IQH) regime, the so-called “Coulomb-dominated” interference has only recently been confirmed in the fractional quantum Hall (FQH) regime, where its observation has remained limited to the simplest and most robust FQH states. Building on our recent observation and analysis of this type of interference at several fractional filling factors, we report on interferometer design improvements yielding greater visibility, most notably for weaker FQH states. We find that parameters such as the distance from the gates defining the interferometer to the 2DEG, gate layout, and wafer structure affect the visibility much more in the FQH regime than in the IQH regime. High sensitivity to such parameters is also a characteristic of the second type of interference, believed to arise from a pure Aharonov-Bohm effect, which has been clearly observed only in the IQH regime; we discuss efforts to observe this behavior in the FQH regime.

¹We acknowledge funding from Microsoft Project Q, Harvard CNS, and DOE.

11:51AM Q24.00004 Multipartite wavefunctions for the second Landau level FQHE, SREEJITH GANESH JAYA, The Pennsylvania State University, ARKADIUSZ WÓJS, Wrocław University of Technology, CSABA TOKE, Institute of Physics, University of Pecs, Hungary, JAINENDRA JAIN, The Pennsylvania State University — We study the multipartite wave functions of composite fermions, in which the composite fermions within each partition are correlated differently than those across partitions. These include the Pfaffian wave function at $5/2$ and the Rezayi-Read wave function at $13/5$. Neutral and charged excitations of this state are modeled as neutral and charged excitations created in the individual partitions. We investigate how accurate these wave functions are for certain model three and four body interactions, and whether they are adiabatically connected to the Coulomb solutions. In particular, $5/2$ state for an odd number of particles, which contains at least one unpaired composite fermion, will be considered. We also test how multiple degeneracy arises in this model for quasiparticles and quasiholes.

12:03PM Q24.00005 Excitons in FQH states, MARIA HERMANNNS, Princeton University, THOMAS KVORNING, THORS HANS HANSSON, Stockholm University — Fractional quantum Hall (FQH) states are the first experimentally realized systems that exhibit topological order. For a full understanding of these systems it is crucial to be able to describe not only their ground states and quasihole excitations, but in fact the full low-energy sector. The lowest energy excitations are believed to be neutral quasihole-quasielectron pairs. We present a description of these excitations for a wide range of FQH states. Our method allows us to variationally change the model states without changing any of their topological properties.

12:15PM Q24.00006 Geometrical Description of fractional quantum Hall quasiparticles¹, YEJE PARK, BO YANG, F.D.M. HALDANE, Princeton University — We examine a description of fractional quantum Hall quasiparticles and quasiholes suggested by a recent geometrical approach (F. D. M. Haldane, Phys. Rev. Lett. **108**, 116801 (2011)) to FQH systems, where the local excess electric charge density in the incompressible state is given by a topologically-quantized “guiding-center spin” times the Gaussian curvature of a “guiding-center metric tensor” that characterizes the local shape of the correlation hole around electrons in the fluid. We use a phenomenological energy function with two ingredients: the shear distortion energy of area-preserving distortions of the fluid, and a local (short-range) approximation to the Coulomb energy of the fluctuation of charge density associated with the Gaussian curvature. Quasiparticles and quasiholes of the $1/3$ Laughlin state are modeled as “punctures” in the incompressible fluid which then relax by geometric distortion which generates Gaussian curvature, giving rise to the charge-density profile around the topological excitation.

¹Supported by DOE DE-SC0002140

12:27PM Q24.00007 Model wavefunctions for fractional quantum Hall collective modes¹, BO YANG, F.D.M. HALDANE, ZIXIANG HU, ZLATKO PAPIĆ, Princeton University — We examine the collective modes of primary fractional quantum Hall states which can be represented by Jack polynomial wavefunctions, in particular the $\nu = 1/3$ Laughlin and the $\nu = 1/2$ (or $5/2$) Moore-Read states. Using the extension of Jack Polynomial states (B. A. Bernevig and F. D. M. Haldane, Phys. Rev. Lett. 102, 066802 (2009)) to describe states with excited quasiparticles as well as quasiholes, we model the collective mode as a dipole formed by the combination of a single elementary quasiparticle with a single quasihole. In the Laughlin case, this neutral collective excitation is bosonic, while in the Moore-Read case, it has two forms, one bosonic and one fermionic. For small electric dipole moment (also small momentum and wavenumber) the (variational) energy of this mode lies above the threshold of the continuum of roton-pair (Laughlin) or neutral-fermion-pair (Moore-Read) excitations. In the long-wavelength limit the bosonic mode is a “spin-2” excitation that has an analogy to the “graviton” suggested by a recent geometric approach (F. D. M. Haldane, Phys. Rev. Lett. 108, 116801 (2011)) to FQH systems, while the neutral fermionic mode (present if the “odd-denominator rule” is violated) has “spin-3/2”, and has a possible analogy to the “gravitino”.

¹Supported by DOE DE-SC0002140

12:39PM Q24.00008 Determination of counter-propagating edge modes in the $\nu = 5/2$ fractional quantum Hall state, JENNIFER CANO, University of California, Santa Barbara, CHETAN NAYAK, University of California, Santa Barbara and Microsoft Station Q — Determining the wavefunction that describes the fractional quantum Hall state at $\nu = 5/2$ remains an unresolved question. Two main candidates are the Pfaffian and anti-Pfaffian states. A major difference between the two is the chirality of their neutral Majorana fermion modes, which in the former run parallel to the charged modes and in the latter, anti-parallel. We consider the recent experiment [Bid, A., et al. Nature, 466, 585-590 (2010)], in which counter-propagating, neutral edge modes in the $\nu = 5/2$ state were detected as a change in shot noise at an inter-edge quantum point contact (QPC) when current was injected at a point downstream of the QPC. We present a theoretical description of this experiment. We model the injection by coupling one edge to an external field and determine that the change in noise is incompatible with a parallel-propagating neutral mode. We also consider the injection as heat transfer to the neutral mode and reach the same conclusion. In agreement with experiment, these results are strong evidence in favor of any state with counter-propagating edge modes, such as the anti-Pfaffian, as a model for the $\nu = 5/2$ state.

12:51PM Q24.00009 Geometry of the fractional quantum Hall effect¹, F.D.M. HALDANE, Princeton University — Unlike the integer effect, the incompressible electron fluid that exhibits the fractional effect is *not* invariant under “area-preserving diffeomorphisms” of the guiding-center degrees of freedom. Instead (F. D. M. Haldane, Phys. Rev. Lett. 108, 116801 (2011)), it has a shear modulus that characterizes the energy cost of distortions of the correlation hole around the electrons, and a “guiding-center metric tensor” that exhibits quantum zero-point fluctuations around a preferred shape. In a simple (one-component) fluid, electronic charge-density fluctuations relative to the background set by the magnetic flux density are given by $\delta\rho = (e^*/2\pi)\bar{s}K$, where e^* is the elementary fractional charge, $\bar{s}$ is an integer or half-integer “guiding-center spin” that is topologically quantized by the Gauss-Bonnet theorem, and K is the local Gaussian curvature of the guiding-center metric. These results provide a simple explanation of the seminal 1985 results of Girvin, MacDonald and Platzman on the FQH structure factor and collective mode, which remained unexplained in previous proposed narrative explanations of FQH incompressibility (Ginzburg-Landau Chern-Simons theory, composite fermions, and non-commutative Chern-Simons field theory).

1:03PM Q24.00010 Microscopic nature of the backward propagating neutral edge modes of the “negative” flux FQHE states, YINGHAI WU, SREEJITH GANESH JAYA, JAINENDRA JAIN, The Pennsylvania State University — It is believed that FQHE states that require antiparallel vortex attachment, e.g. $2/3$, have neutral modes propagating in the backward direction. Recent experiments have observed signatures of such modes. We study the edge excitations of the fully spin polarized as well as spin singlet $2/3$ state both from exact diagonalization and from the microscopic composite fermion (CF) theory, to gain insight into the microscopic nature of the neutral edge modes. We investigate the validity of the CF theory for the edge modes, and also study the dependence on the form of the interaction and the background potential. We further evaluate the spectral weights and compare them with the predictions from the effective bosonic description.

1:15PM Q24.00011 Braiding statistics of the Gaffnian through the coherent state representation¹, JOHN FLAVIN, ALEXANDER SEIDEL, Washington University in St. Louis — Certain quantum Hall states have trial wave functions that can be connected to non-unitary conformal field theories, and arguments exist implying that such wave functions cannot describe gapped states. For these trial wave functions, the question arises whether braiding statistics may still be well defined through a formal Berry phase calculation. In essence, this corresponds to assuming an artificial gap to “non-zero modes” introduced by non-local terms in the Hamiltonian. The presence of long ranged correlations may still foil the emergence of well defined statistics. However, assuming that this is not the case, the question of what such statistics would be, and how they compare to those defined in terms of conformal block monodromies, can be analyzed using a recently developed coherent state Ansatz based on the thin torus limit. We report pertinent results for the Gaffnian state. Time and/or results permitting, we also present developments on the application of this method to a state by Thomale *et al.*, the associated conformal field theory of which is currently unknown. [References: S. Simon *et al.*, Phys. Rev. B 75, 075317 (2007), J. Flavin and A. Seidel, arXiv:1108.2734v1, N. Read, Phys. Rev. B 79, 045308 (2009)]

1:27PM Q24.00012 Gapless excitations in the Haldane-Rezayi state: The thin-torus limit¹, ALEXANDER SEIDEL, Department of Physics and Center for Materials Innovation, Washington University, St. Louis, MO 63130, USA, KUN YANG, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32306, USA — We study the thin-torus limit of the Haldane-Rezayi state. Eight of the ten ground states are found to assume a simple product form in this limit, as is known to be the case for many other quantum Hall trial wave functions. The two remaining states have a somewhat unusual thin-torus limit, where a “broken” pair of defects forming a singlet is completely delocalized. We derive these limits from the wave functions on the cylinder, and deduce the dominant matrix elements of the thin-torus hollow-core Hamiltonian. We find that there are gapless excitations in the thin-torus limit. This is in agreement with the expectation that local Hamiltonians stabilizing wave functions associated with non-unitary conformal field theories are gapless. We also use the thin-torus analysis to obtain explicit counting formulas for the zero modes of the hollow-core Hamiltonian on the torus, as well as for the parent Hamiltonians of several other paired and related quantum Hall states. [Reference: A. Seidel, K. Yang, PRB 84, 085122 (2011)]

1:39PM Q24.00013 Dependence of pinning modes of 2D electron system on short-ranged alloy disorder , B.H. MOON, B.A. MAGILL, L.W. ENGEL, NHMFL/FSU, D.C. TSUI, L.N. PFEIFFER, K.W. WEST, Princeton University — A 2D electron system (2DES) in a low Landau filling (ν) pinned Wigner solid state exhibits a striking resonance in its rf or microwave spectrum. The resonance is understood as a pinning mode, in which the electrons oscillate about their pinned positions, and the frequency (f_{pk}) increases for larger disorder. We report on microwave spectroscopy of the low- ν Wigner solids in $\text{Al}_x\text{Ga}_{1-x}\text{As}-\text{Al}_{0.1}\text{Ga}_{0.9}\text{As}$ heterojunctions with $x=0.4$ and 0.8% . The 2DES resides mainly in the dilute $\text{Al}_x\text{Ga}_{1-x}\text{As}$, and the alloy disorder has been shown to be randomly distributed [1]. We compare the pinning modes of the samples as density (n , controlled by backgates) and magnetic field are varied. For example, with densities around $n \sim 6.5 \times 10^{10} \text{cm}^{-2}$ (in sample state with no indication of a $1/5$ fractional quantum Hall effect) $f_{pk} \approx 5.93$ and 8.55 GHz at $\nu \sim 0.2$ for $x=0.4$ and 0.8% respectively.

1:51PM Q24.00014 Local Thermometry of Neutral Modes on the Quantum Hall Edge , SEAN HART, VIVEK VENKATACHALAM, Harvard University, LOREN PFEIFFER, KEN WEST, Princeton University, AMIR YACOBY, Harvard University — A system of electrons in two dimensions and strong magnetic fields can be tuned to create a gapped 2D system with one dimensional channels along the edge. Interactions among these edge modes can lead to independent transport of charge and heat, even in opposite directions. Measuring the chirality and transport properties of these charge and heat modes can reveal otherwise hidden structure in the edge. Here, we heat the outer edge of such a quantum Hall system using a quantum point contact. By placing quantum dots upstream and downstream along the edge of the heater, we can measure both the chemical potential and temperature of that edge to study charge and heat transport, respectively. We find that charge is transported exclusively downstream, but heat can be transported upstream when the edge has additional structure related to fractional quantum Hall physics.

2:03PM Q24.00015 Real Space Entanglement Spectrum of Fractional Hall States , EDWARD REZAYI¹, CSU Los Angeles, JEROME DUBAIL², NICHOLAS READ³, Yale University — The entanglement spectrum has been shown by Li and Haldane to provide a reliable tool to detect the topological order of Hall states. For example, bi-partitioning the system in orbital space produces the signature count of Hall edge states. The spectrum, however, appears to bear no resemblance to the linear spectrum conjectured by Kitaev and Preskill analogous to the actual edge mode dispersion. Here we employ two types of cuts: a real space and a modified particle bi-partitioning. On the sphere, we obtain the entanglement spectrum for the Laughlin, Moore-Read and Read-Rezayi states for both. We also consider the filled Landau level with a real space cut and show that the Laughlin state for $\nu=1/3$ has the same count of levels, which agrees with the chiral CFT (for up to $\Delta M = N/2$, $\Delta M = L_{\text{max}} - L_z$). Moreover, the entanglement spectrum of the Laughlin state approaches a linear spectrum, similar to the filled Landau level, as the size of the system increases.

11:15AM Q25.00001 Metallization of FeO at High Temperatures and Pressures: DFT-DMFT Computations and Comparisons with Experiments , R.E. COHEN, Geophysical Laboratory, Carnegie Institution, KRISTJAN HAULE, Dept. Physics, Rutgers University — DFT+Dynamical Mean Field Theory (DMFT) was applied to FeO as a function of pressure and temperature. We use an LAPW basis set, and the lattice terms are evaluated using the WIEN2K LAPW code. The impurity model is solved using continuous time quantum Monte Carlo (CTQMC). Temperature enters explicitly, so we made special efforts to understand high temperature behavior. The computations are fully self-consistent, including the impurity levels and crystal field splitting, and the total energy is evaluated using the full potential and charge density of the lattice plus impurity models. We find with increasing pressure in paramagnetic FeO in a cubic lattice and $U=8$ eV a high-spin low-spin transition, with a wide transition region between characterized by intermediate occupancies of the t_{2g} and e_g states between. We find that at 300K cubic FeO remains insulating to a factor of two compression (over 600 GPa), except for a small region of high spin metal. However, at high temperatures (e.g. 2000K) a metallic state is found. We find excellent agreement with recent high temperature high pressure experiments (Ohta et al.). We are now studying the antiferromagnetic ordering and effects of lattice strain.

11:27AM Q25.00002 ABSTRACT WITHDRAWN —

11:39AM Q25.00003 Finite-temperature solid phases and melting of denser lithium¹ , SABRI ELATRESH, Department of Physics, Dalhousie University, Halifax, NS, B3H 3J5, Canada, STANIMIR BONEV, Department of Physics, Dalhousie University, Halifax, NS, B3H 3J5, Canada; Lawrence Livermore National Laboratory, Livermore, California 94550 — There has been a lot of recent interest in lithium at high pressure, in particular, in relation to deviations from simple metallic behavior, non-intuitive structural changes, and its anomalous melting curve. Most of the theoretical studies have been limited to 0 K static lattices and liquid properties with classical ions. In this talk, we will present results for the stability of lithium up to 250 GPa and finite temperature, as well as its melting curve. Comparison with experimental measurements and the significance of quantum ion dynamics for the observed properties will be discussed.

11:51AM Q25.00004 Study on the release process of γ and α phase transition in cerium material , XIAOMIAN HU, HAO PAN, National Key Laboratory of Computational Physics, Institute of Applied Physics and Computational Mathematics, Beijing 100088, China, CHENGDA DAI, QIANG WU, Laboratory for Shock Wave and Detonation Physics Research, Institute of Fluid Physics, China Academy of Engineering Physics, Mianyang 621900, China, NATIONAL KEY LABORATORY OF COMPUTATIONAL PHYSICS, INSTITUTE OF APPLIED PHYSICS AND COMPUTATIONAL MAT TEAM, LABORATORY FOR SHOCK WAVE AND DETONATION PHYSICS RESEARCH, INSTITUTE OF FLUID PHYSICS, CHINA ACADEMY COLLABORATION — Cerium has lots of phase transition in high pressure and temperature. A volume change of about 15% occurs when Cerium is subject to high pressure (~ 0.7 GPa) and $\gamma \rightarrow \alpha$ phase change takes place. The phase transition and constitutive model of Cerium can be respectively obtained by calculating the experiment results and taking account of the multi-phase equation of state (EOS). The calculated results indicate that in loading condition the phase transition pressure of Cerium is higher than quasi-static compression. The calculated results indicate that the phase transition under release is difficultly described because the $\alpha \rightarrow \gamma$ phase reversal is great influenced by plastic flow. Based on multi-phase equation of state, constitutive model and non-equilibrium phase transition equation, introducing quasi-elastic unloading rule simulated the phase transition under release. The calculated result is according with the experiment.

12:03PM Q25.00005 Stability of dense liquid carbon dioxide¹, BRIAN BOATES, Lawrence Livermore National Laboratory, Dalhousie University, AMANUEL TEWELDEBERHAN, Lawrence Livermore National Laboratory, STANIMIR BONEV, Lawrence Livermore National Laboratory, Dalhousie University — We have used first-principles molecular dynamics to identify a transition from molecular liquid CO₂ to a new polymeric liquid phase under compression. The phase transition is first-order and unlike other such transitions, is not accompanied by metallization. The region near the liquid-liquid-solid triple point is particularly interesting as it coincides with pressure-temperature conditions inside the Earth's mantle. We have characterized the stability of CO₂ under these conditions; contrary to previous studies, our calculations show that CO₂ does not phase separate into carbon and oxygen. Comparisons with and alternative interpretations of previous measurements will be presented. Routes for experimental detection of our predictions will also be discussed.

12:15PM Q25.00006 On the stability of body-centered cubic Fe at Earth's core conditions, VEKILOVA OLGA, SIMAK SERGEI, ABRIKOSOV IGOR, Linköping University, Linköping, Sweden — Elucidation of Earth's core content and structure is extremely important for understanding Earth's behavior influencing human life, from geodynamics to earthquakes. Though cosmochemical and geochemical studies strongly suggest that solid Fe is the main constituent of the inner core, its exact content and crystal structure are still a matter of debate. The recent experiments reported controversial results of phase stability. Dubrovinsky *et al.* showed stabilization of the body centered cubic (bcc) phase of Fe alloyed with 10 at. % of Ni at pressures above 225 GPa and temperatures over 3400 K [1]. Tateno *et al.* on pure Fe at up to 377 GPa and 5700 K, no bcc phase was observed [2]. We offer a resolution of this contradiction based on finite temperature first-principles molecular dynamics calculations of elastic properties of both bcc Fe and Fe₉₀Ni₁₀ alloy at high-temperature high-pressure conditions. We indicate the stability range for the bcc phase of high-pressure high-temperature Fe and show how experimental conditions may cause diverse phase stabilization. REFERENCES [1] L. S. Dubrovinsky *et al.* Body-centered cubic iron-nickel alloy in Earth's core. *Science* **316**, 1880-1883 (2007). [2] S. Tateno, K. Hirose, Y. Ohishi, Y. Tatsumi. 12:27PM Q25.00007 Thermoelastic Properties of Olivine and its High Pressure Polymorphs at High Pressures and Temperatures: A First-Principles Study¹, MARIBEL NÚÑEZ VALDEZ, School of Physics and Astronomy, University of Minnesota, ZHONGQIN WU, School of Earth and Space Sciences, University of Science and Technology of China, YOUNGGANG YU, Department of Chemical Engineering and Materials Science, University of Minnesota, RENATA WENTZCOVITCH, Department of Chemical Engineering and Materials Science, Minnesota Supercomputing Institute (MSI), University of Minnesota — We combine density functional theory (DFT) within the local density approximation (LDA), the quasi-harmonic approximation (QHA), and a model of vibrational density of states (VDoS) to calculate aggregate elastic moduli and sound velocities of olivine (α -phase) (Fe_xMg_{1-x})₂SiO₄, and its high pressure polymorphs, wadsleyite (β -phase) and ringwoodite (γ -phase), the most abundant minerals of the Earth's upper mantle (UM) and transition zone (TZ). Comparison of results with high-pressure and room-temperature data and ambient-pressure and high-temperature data shows very good agreement. Using our findings, we investigate the discontinuities in elastic moduli and velocities associated with the α to β and β to γ transformations at pressures and temperatures relevant to seismic discontinuities near 410 km and 520 km depth. This information offers clearly defined reference values to advance understanding of the role that chemical composition and temperature play in these mantle boundary layers.

12:39PM Q25.00008 Fate of MgSiO₃ post-perovskite at multi-Mbar pressures¹, KOICHIRO UMEMOTO, University of Minnesota, SHUNQING WU, Iowa State University and Xiamen University, China, MIN JI, CAI-ZHUANG WANG, KAI-MING HO, Iowa State University, RENATA WENTZCOVITCH, University of Minnesota — The discovery of the post-perovskite (PPV) transition of MgSiO₃ in 2004 invited a new question: What would be the next phase transition from the PPV phase? The importance of this question has increased, since many terrestrial exoplanets with masses of a few to 10 times Earth's (super-Earth) have been recently discovered. Here we predict the new class of phase transitions of MgSiO₃ PPV under ultrahigh pressure by first-principles calculations combined with the adaptive genetic algorithm, which is a powerful tool for blind structural searches for systems with the large number of atoms. We discuss implications of these new phase transitions in modeling of interiors of terrestrial exoplanets.

12:51PM Q25.00009 Raman study of the Verwey transition in Magnetite at high-pressure and low-temperature; effect of Al doping¹, LEV GASPAROV, Z. SHIRSHIKOVA, T.M. PEKAREK, J. BLACKBURN, Department of Physics, University of North Florida, Jacksonville, FL, STRUZHUKIN, A. GAVRILIUK², Geophysical Laboratory, Carnegie Institution of Washington, Washington D.C., R. RUECKAMP, University of Cologne, Institute of Physics 2, Cologne, Germany, H. BERGER, Ecole Polytechnique Fédérale de Lausanne, Switzerland — We report high-pressure low-temperature Raman measurements of the Verwey transition in pure and Al-doped magnetite (Fe₃O₄) Al-doped magnetite Fe_{2.8}Al_{0.2}O₄ (T_V=116.5K) displays a nearly linear decrease of the transition temperature with an increase of pressure yielding dP/dT_V=-0.096±0.013 GPa/K. In contrast pure magnetite displays a significantly steeper slope of the PT equilibrium line with dP/dT_V = -0.18±0.013 GPa/K. Contrary to earlier high pressure resistivity reports we do not observe quantum critical point behavior at 8 GPa in the pure magnetite. Our data indicates that Al doping leads to a smaller entropy change and larger volume expansion at the transition. The trends displayed by the data are consistent with the mean field model of the transition that assumes charge ordering in magnetite.

1:03PM Q25.00010 Magnetic and Thermal Fluctuations in Fe and (Fe,Ni) alloys at Earth Core Conditions¹, SUFIAN ALNEMRAT, BORIS KIEFER, New Mexico State University — Several lines of evidence suggest that the earth's inner core is dominated by an iron rich (Fe,Ni) alloy. In this study we address the influence of magnetic and thermal fluctuations as driving forces for phase transitions in Fe and Fe₇Ni structures at inner core pressure and temperature conditions. Bcc iron is stable at ambient conditions due to its ferromagnetic nature which highlights the importance of magnetism for structural stability. *Ab-initio* electronic structure calculations are used to study the thermal and magnetic fluctuations in Fe and (Fe,Ni) alloys up to pressures and temperatures expected in the earth's inner core. The variable cell shape molecular-dynamics simulations include the magnetic moment and thermal fluctuations. Our preliminary results show a phase transformation in hcp-Fe₇Ni alloy that occurs after 2.5 ps, well after equilibration. The correlation of magnetic and thermal fluctuations suggests that the residual magnetism is too weak to induce the observed transition. Instead, large thermal fluctuations at the onset of the transition provide a likely driving force.

¹The authors gratefully acknowledge funding from NSF through grant EAR-0636075.

1:15PM Q25.00011 Mechanism of body-centered cubic phase stabilization in Fe and He at high pressure and temperature, ANATOLY BELONOSHKO, KTH Royal Institute of Technology, Stockholm, Sweden, SERGIU ARAPAN, Uppsala University, Uppsala, Sweden, LOVE KOCL, AWA Patent AB, Stockholm, Sweden, ANDERS ROSENGREN, KTH Royal Institute of Technology, Stockholm, Sweden — We have investigated the stabilization of the body-centered cubic phase in Fe and He at high P and T by means of *ab initio* and classical molecular dynamics. These phases are dynamically unstable at high P and low T, however, they become dynamically stable at high T. We calculated the phonon density of states for Fe and He phases and observed that the bcc PDOS contains long-wavelength phonon states (absent in the close packed phases) that contribute to the free energy. This observation is consistent with the mechanism of stabilization proposed earlier (P. Loubeyre, J.-P. Hansen, PRB 31, 634 (1985); B. L. Holian et al., JCP 59, 5444 (1973)). Direct *ab initio* simulations of Fe crystallization and classical co-existence simulations for He indicate that the bcc phase is a submelting phase at high P. Previous calculations of the free energy in the bcc phase have been performed on small samples and could not adequately take the long-wavelength correlated motion into account.

1:27PM Q25.00012 ABSTRACT WITHDRAWN —

1:39PM Q25.00013 Computation of free energy of liquids and its application to melting of CO₂ and N¹, AMANUEL TEWELDEBRHAN, Lawrence Livermore National Lab, BRIAN BOATES, STANIMIR BONEV, Dalhousie University and Lawrence Livermore National Lab — A computationally efficient method is proposed to compute the free energy of liquids with accuracy comparable to *ab initio* thermodynamic integration. The method has been applied to predict melting curves of CO₂ and N over a wide range of pressure using the solid-liquid phase coexistence approach. The calculated melting lines are compared with available experimental data and the crossing of the geotherm and melting line of CO₂ is determined.

1:51PM Q25.00014 Melting behaviour of high pressure Na. An *ab initio* study, DAVID J. GONZALEZ, Dpt Fisica Teorica, Universidad de Valladolid, Valladolid, LUIS E. GONZALEZ, Dpt Fisica Teorica, Universidad de Valladolid, Valladolid — The melting curve of sodium for a pressure range up to 120 GPa has been evaluated by the orbital free *ab initio* molecular dynamics method. This method uses the electronic density as the basic variable and scales almost linearly with system size which allows to perform simulations with a large number of particles and for long simulation times. For various pressures and temperatures we have calculated some static properties (pair distribution functions, static structure factors and short-range order parameters), dynamic properties (mean square displacement, velocity autocorrelation functions and dynamic structure factors) and transport coefficients (self-diffusion, adiabatic sound velocities and shear viscosities). The calculated melting curve reproduces the main qualitative features found in the experiment.

Session Q26 DCOMP: Focus Session: Computational Frontiers in Quantum Spin Systems I

257B

11:15AM Q26.00001 Computing Entanglement Entropy in Quantum Monte Carlo, ROGER MELKO, University of Waterloo — The scaling of entanglement entropy in quantum many-body wavefunctions is expected to be a fruitful resource for studying quantum phases and phase transitions in condensed matter. However, until the recent development of estimators for Renyi entropy in quantum Monte Carlo (QMC), we have been in the dark about the behaviour of entanglement in all but the simplest two-dimensional models. In this talk, I will outline the measurement techniques that allow access to the Renyi entropies in several different QMC methodologies. I will then discuss recent simulation results demonstrating the richness of entanglement scaling in 2D, including: the prevalence of the “area law”; topological entanglement entropy in a gapped spin liquid; anomalous subleading logarithmic terms due to Goldstone modes; universal scaling at critical points; and examples of emergent conformal-like scaling in several gapless wavefunctions. Finally, I will explore the idea that “long range entanglement” may complement the notion of “long range order” for quantum phases and phase transitions which lack a conventional order parameter description.

11:51AM Q26.00002 Scaling of entanglement entropy in the 2D Heisenberg ground state, ANN KALLIN, University of Waterloo, HYEJIN JU, University of California, Santa Barbara, PAUL FENDLEY, University of Virginia, Microsoft Station Q, MATTHEW HASTINGS, Duke University, Microsoft Station Q, ROGER MELKO, University of Waterloo — We use a Loop-Ratio Valence Bond quantum Monte Carlo algorithm to study the scaling of the bipartite Renyi entanglement entropy in the 2D Heisenberg ground state. We uncover the surprising result that finite-size scaling supports a logarithmic correction to the entropic area law even with the absence of corners in the entangled region. In addition, examining the scaling within a single system, we observe an aspect-ratio dependent scaling term resembling the “conformal distance” term that appears in one-dimensional systems with conformal symmetry.

12:03PM Q26.00003 Entanglement scaling of the 2D RVB wavefunction, HYEJIN JU, University of California, Santa Barbara, ANN KALLIN, University of Waterloo, PAUL FENDLEY, University of Virginia, Microsoft Station Q, MATTHEW HASTINGS, Duke University, Microsoft Station Q, ROGER MELKO, University of Waterloo — The resonating valence bond (RVB) state on a two-dimensional lattice is a superposition of all permutations of singlet spin pairs. This wavefunction was first proposed by Anderson as a simple spin liquid ground state, showing no long range order at T=0. Using a loop-algorithm Monte Carlo method that samples all nearest-neighbor singlet pairs, we examine the entanglement entropy of the nearest neighbor SU(2) RVB wavefunction on the square lattice. In addition to the area law, we show that the entanglement entropy splits into two branches, due to the different topological sectors of the RVB wavefunction. These branches individually scale with a logarithmic dependence on the size of the entangled region, the functional form of which appears to be similar to the conformal distance observed in scaling at conformal critical points in 1D. We comment on the implication for the search for topological order, and on generalizations of this wavefunction, including models involving SU(N) spins.

12:15PM Q26.00004 Entanglement entropy at the quantum critical point of the 2D transverse field Ising model, STEPHEN INGLIS, ROGER MELKO, University of Waterloo, RAJIV SINGH, University of California, Davis, ANDERS SANDVIK, Boston University — Entanglement entropy is a quantity that is desirable to examine at quantum critical points in condensed matter systems, because it is expected that sub-leading scaling terms should contain universal coefficients. In dimensions higher than one, these universal coefficients (that are sub-leading to the area law) may possibly be used to identify the universality class of the quantum critical point, much like the central charge in 1D systems. The recent development of zero temperature projector methods for the transverse field Ising model in combination with replica methods for stochastic series expansion quantum Monte Carlo (QMC) allows us to examine this idea, using measurements of Renyi entanglement entropies. We compare zero- and finite- temperature QMC results with series expansion, and discuss the scaling of the Renyi entropies at the 2D critical point in the transverse field Ising model.

12:27PM Q26.00005 Finite entanglement scaling at novel phase transitions in the Bose-Hubbard model with pairing terms

MICHAEL ZALETEL, ROGER MONG, JOEL MOORE, University of California, Berkeley — With the introduction of pair hopping, the 1+1D Bose-Hubbard model contains string like defects and half vortices in addition to the familiar vortices that drive the Kosterlitz - Thouless (KT) transition. Recent work [1] proposed the existence of a novel phase transition directly from the insulating to superfluid phase which is partly of an Ising, rather than KT type, contrary to expectations based on symmetry. To characterize the transition we demonstrate an approach to the study of 1+1D critical phenomena using infinite matrix product state algorithms (iMPS), in which critical fluctuations are cut off not by a finite system size, but by the finite entanglement of the iMPS ansatz. Starting from the “finite entanglement” scaling of the correlation length [2], we show that scaling and correlation functions also admit a universal “finite entanglement” collapse, avoiding boundary effects and validating an elegant alternative to finite size scaling methods for critical phases.

12:39PM Q26.00006 Renormalization of tensor-network states¹

TAO XIANG, HUI-HAI ZHAO, Institute of Physics, Chinese Academy of Sciences, ZHI-YUAN XIE, QIAO-NI CHEN, Institute of Theoretical Physics, Chinese Academy of Sciences, ZHONG-CHAO WEI, Institute of Physics, Chinese Academy of Sciences — We have discussed the tensor-network representation of classical statistical or interacting quantum lattice models, and given a comprehensive introduction to the numerical methods we recently proposed for studying the tensor-network states/models in two dimensions. A second renormalization scheme is introduced to take into account the environment contribution in the calculation of the partition function of classical tensor network models or the expectation values of quantum tensor network states. It improves significantly the accuracy of the coarse grained tensor renormalization group method. In the study of the quantum tensor-network states, we point out that the renormalization effect of the environment can be efficiently and accurately described by the bond vector. This, combined with the imaginary time evolution of the wave function, provides an accurate projection method to determine the tensor-network wave function. It reduces significantly the truncation error and enables a tensor-network state with a large bond dimension, which is difficult to be accessed by other methods, to be accurately determined.

12:51PM Q26.00007 Cluster update for tensor network states¹

LING WANG, FRANK VERSTRAETE, Faculty of Physics, University of Vienna, IQI TEAM — We propose a novel recursive way of updating the tensors in projected entangled pair states by evolving the tensor in imaginary time evolution on clusters of different sizes. This generalizes the so-called simple update method of Jiang et al. [Phys. Rev. Lett. 101, 090603 (2008)] and the updating schemes in the single layer picture of Pizorn et al. [Phys. Rev. A 83, 052321 (2011)]. A finite-size scaling of the observables as a function of the cluster size provides a remarkable improvement in the accuracy as compared to the simple update scheme. We benchmark our results on the hand of the spin 1/2 staggered dimerized antiferromagnetic model on the square lattice, and accurate results for the magnetization and the critical exponents are determined. Reference L. Wang and F. Verstraete, arXiv:1110.4362.

1:03PM Q26.00008 The spin 1/2 J1-J2 Antiferromagnetic Heisenberg model on Square Lattice

FRANK VERSTRAETE, LING WANG, Faculty of Physics, University of Vienna, ZHENG-CHENG GU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, XIAO-GANG WEN, Department of Physics, Massachusetts Institute of Technology, ANDERS SANDVIK, Department of Physics, Boston University, VERSTRAETE'S GROUP COLLABORATION, WEN'S GROUP COLLABORATION, SANDVIK'S GROUP COLLABORATION — We studied the spin 1/2 J1-J2 Heisenberg antiferromagnets on square lattice using the recently proposed cluster update for tensor network states [arXiv:1110.4362]. Ground state wavefunction with tensor network bond dimension upto $D = 9$ was obtained. Through a finite size scaling analysis, we observe a second order phase transition from an antiferromagnetic ordered state to a paramagnetic phase with plaquette valence bond order at a coupling constant ratio $J_2/J_1 \approx 0.44$. The ground state energies in the thermodynamic limit are in the order of $10^{-3} J_1$ per site difference from the state of art exact diagonalization study [Eur. Phys. J. B 73, 117 (2010)].

1:15PM Q26.00009 The spin-1/2 $J_1 - J_2$ Heisenberg antiferromagnet on a square lattice: a plaquette renormalized tensor network study¹

YING-JER KAO, JI-FENG YU, Department of Physics, National Taiwan University — We apply the plaquette renormalization scheme of tensor network states [Phys. Rev. E, 83, 056703 (2011)] to study the spin-1/2 frustrated Heisenberg J_1 - J_2 model on an $L \times L$ square lattice with $L=8, 16$ and 32 . By treating tensor elements as variational parameters, we obtain the ground states for different J_2/J_1 values, and investigate staggered magnetizations, nearest-neighbor spin-spin correlations and plaquette order parameters. In addition to the well-known Néel-order and collinear-order at low and high J_2/J_1 , we observe a plaquette-like order at $J_2/J_1 \approx 0.5$. A continuous transition between the Néel order and the plaquette-like order near $J_2^{c1} \approx 0.40 J_1$ is observed. The collinear order emerges at $J_2^{c2} \approx 0.62 J_1$ through a first-order phase transition.

1:27PM Q26.00010 MERA Study of Spatially Anisotropic Triangular Antiferromagnets

KENJI HARADA, Graduate School of Informatics, Kyoto University, Japan, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo, Japan — We report variational calculations for the ground states in the spatially anisotropic triangular antiferromagnets. The variational wave function is based on the tensor network with an entanglement renormalization [1]. The entanglement renormalization improves the ability of describing a quantum state. We construct a three-dimensional MERA tensor network for the triangular lattice models. The model in this study has two groups of the antiferromagnetic Heisenberg couplings on a triangular lattice: one on links along a lattice axis and the other on other links. J_1 and J_2 denote the coefficient of their couplings, respectively. We calculate the ground states of finite lattices ($N = 114, 2166$) and an infinite lattice. We confirm a magnetic phase in the region of $0.7 < J_2/J_1 \leq 1$. The magnetic structure is incommensurate, and the wave vector is not consistent with that of a classical model except for $J_1 = J_2$.

1:39PM Q26.00011 General framework of non-Abelian $SU(N)$ symmetries for matrix product states, ANDREAS WEICHSELBAUM, JAN VON DELFT, Ludwig Maximilians University, Munich, Germany — We present a generic numerical framework for the treatment of an arbitrary set of non-abelian quantum symmetries within the matrix product states (MPS) approach and generalization thereof. The framework is based on the simple observation that Clebsch Gordan coefficient spaces can be split off as tensor products for all objects relevant within MPS [1]. As such it is applicable, for example, to the numerical as well as the density matrix renormalization group (NRG or DMRG, respectively). The framework is applied to a generalized $SU(3)$ channel-symmetric Anderson impurity model within the NRG. This model of a fully screened spin $S = \frac{3}{2}$ Anderson model has been suggested recently as the effective microscopic Kondo model for Fe impurities in gold or silver [2]. Results are presented on the explicit treatment of $U(1) \otimes SU(2) \otimes SU(3)$ for charge, spin, and channel, respectively. This is compared to the alternative description in terms of $SU(2)^{\otimes 4}$ symmetries for total spin and particle-hole symmetry in every channel.

1:51PM Q26.00012 Reducing Memory Cost of Exact Diagonalization using Singular Value Decomposition, MARVIN WEINSTEIN, SLAC National Accelerator Laboratory, RAVI CHANDRA, ASSA AUERBACH, Technion, Haifa — We present a modified Lanczos algorithm to diagonalize lattice Hamiltonians with dramatically reduced memory requirements. In contrast to variational approaches and most implementations of DMRG, Lanczos rotations towards the ground state do not involve incremental minimizations, (e.g. sweeping procedures) which may get stuck in false local minima. The lattice of size N is partitioned into two subclusters. At each iteration the rotating Lanczos vector is compressed into two sets of n_{svd} small subcluster vectors using singular value decomposition. For low entanglement entropy S_{ee} , (satisfied by short range Hamiltonians), the truncation error is bounded by $\exp(-n_{\text{svd}}^{1/S_{ee}})$. Convergence is tested for the Heisenberg model on Kagomé clusters of 24, 30 and 36 sites, with no lattice symmetries exploited, using less than 15GB of dynamical memory. Generalization of the Lanczos-SVD algorithm to multiple partitioning is discussed, and comparisons to other techniques are given. Reference: arXiv:1105.0007

2:03PM Q26.00013 An efficient basis for the modeling of doped and undoped $S=1/2$ antiferromagnet¹, BAYO LAU, Department of Physics, Columbia University, NY, NY, MONA BERCIU, GEORGE A. SAWATZKY, Department of Physics and Astronomy, University of British Columbia, Vancouver, British Columbia, V6T 1Z1 — We formulate an efficient numerical basis to model both doped and undoped $S=1/2$ Heisenberg antiferromagnet (AFM) with two-dimensional periodic boundary condition (2DPBC). Using a linear combination of Slater determinants with total-spin symmetries, a variational approach is developed to systematically and combinatorially decreases the Hilbert space of the problems, allowing the application of exact diagonalization to record-breaking system sizes. We can now model explicitly the wavefunction of an undoped 64-spin AFM square lattice with 2DPBC. For the doped scenarios, we solve a half-filled lattice with 32 coppers and 64 oxygens with one or two electrons removed. This allows, for the first time, a direct comparison of 32-unit-cell exact diagonalization between multi-band model and the t-J model, quantifying several oxygen-specific properties relevant to the lightly doped cuprate structures.

Session Q27 DCMP: Invited Session: DCMP Prize Session: Buckley, Isakson, MGM 258AB

11:15AM Q27.00001 Oliver E. Buckley Condensed Matter Prize Lecture: Topological Insulators¹, CHARLES KANE, University of Pennsylvania — A topological insulator is a material that is an insulator on its interior, but has special conducting states on its surface. These surface states are unlike any other known two dimensional conductor. They are characterized by a unique Dirac type dispersion relation and are protected by a topological property of the material's underlying electronic band structure. In this talk we will outline our path to the theoretical discovery of this phase and describe the physical properties of the two dimensional topological insulator - also known as a quantum spin Hall insulator - as well as its three dimensional generalization. We will then go on to discuss more recent developments, including the topological classification of point and line defects in topological insulators and superconductors. The latter may provide a venue for observing Majorana fermion states and for realizing proposals for topological quantum computation.

¹Supported by NSF grant DMR-0906175.

11:51AM Q27.00002 HgTe as a Topological Insulator, LAURENS W. MOLENKAMP, Physics Institute(EP3), Wuerzburg University — HgTe is a zincblende-type semiconductor with an inverted band structure. While the bulk material is a semimetal, lowering the crystalline symmetry opens up a gap, turning the compound into a topological insulator. The most straightforward way to do so is by growing a quantum well with (Hg,Cd)Te barriers. Such structures exhibit the quantum spin Hall effect, where a pair of spin polarized helical edge channels develops when the bulk of the material is insulating. Our transport data provide very direct evidence for the existence of this third quantum Hall effect, which now is seen as the prime manifestation of a 2-dimensional topological insulator. To turn the material into a 3-dimensional topological insulator, we utilize growth induced strain in relatively thick (ca. 100 nm) HgTe epitaxial layers. The high electronic quality of such layers allows a direct observation of the quantum transport properties of the 2-dimensional topological surface states.

12:27PM Q27.00003 Oliver E. Buckley Condensed Matter Prize Lecture: Topological insulators and superconductors¹, SHOUCHENG ZHANG, Stanford University — In this talk I shall briefly review the basic concepts of topological insulators and superconductors, and recall the history of the discovery of the first topological insulator in nature, the HgTe material. I will then describe some striking physical properties of topological insulators and their possible applications.

1:03PM Q27.00004 Frank Isakson Prize for Optical Effects in Solids Lecture: Infrared nano-spectroscopy and nano-imaging of Dirac plasmons in graphene, DMITRI BASOV, UCSD — We have applied antenna-based infrared (IR) nano-spectroscopy and nano-imaging to investigate Dirac plasmons in monolayer graphene. This experimental technique enables IR imaging with nano-scale spatial resolution, and also allows one to investigate electromagnetic phenomena at wave-vectors on the order of the Fermi wave-vector in gated graphene. Nano-spectroscopy and nano-imaging experiments have uncovered rich optical effects associated with the Dirac plasmons of graphene [Fei *et al.* *Nano Letters* 2011]. We were able to directly image Dirac plasmons propagating over sub-micron distances and reflecting from the edges of graphene flakes, all with a spatial resolution far exceeding the plasmon wavelength. Furthermore, we employed new IR nano-optics capabilities to demonstrate the gate-tunable plasmonic properties of graphene and to investigate the coupling between Dirac plasmons and the phonon modes of polar substrates.

1:39PM Q27.00005 Maria Goeppert Mayer Award Lecture: Spectroscopy of Hybrid Superconductor-Carbon Nanostructure Systems, NADYA MASON, University of Illinois at Urbana-Champaign — The electronic properties of carbon nanotubes and graphene have excited much interest, for both fundamental science and technological applications. In this talk, I will discuss how coupling superconductors to these carbon nanostructures can enable new spectroscopic tools. In particular, I will discuss our experiments demonstrating that superconducting probes on carbon nanotube quantum dots can enhance weak spectroscopic features. I will also show how superconducting tunnel probes enable direct measurements of electron-electron interactions in carbon nanotubes. Finally, I will present data showing that connecting graphene to superconductors allows for the spectroscopy of individual, tunable superconducting (Andreev) bound states.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q28 FIAP: Applications of Semiconductors, Dielectrics, Complex Oxides 258C

11:15AM Q28.00001 Anatomy of a Nanoscale Conduction Channel Reveals the Mechanism of a High-Performance Memristor, FENG MIAO, JOHN PAUL STRACHAN, J. JOSHUA YANG, WEI YI, ILAN GOLDFARB, M.-X. ZHANG, ANTONIO C. TORREZAN, Hewlett-Packard Laboratories, Palo Alto, CA, PETER ESCHBACH, RONALD D. KELLEY, Hewlett-Packard, Corvallis, OR, GILBERTO MEDEIROS-RIBEIRO, R. STANLEY WILLIAMS, Hewlett-Packard Laboratories, Palo Alto, CA — Two major challenges for resistance memory devices (memristors) based on conductivity changes in oxide materials are better performance and understanding of the microscopic picture of the switching. After researchers' relentless pursuit for years, tantalum oxide-based memristors have rapidly risen to be the top candidate, showing fast speed, high endurance and excellent scalability. While the microscopic picture of these devices remains obscure, by employing a precise method for locating and directly visualizing the conduction channel, here we observed a nanoscale channel consisting of an amorphous Ta(O) solid solution surrounded by crystalline Ta₂O₅. Structural and chemical analyses of the channel combined with temperature dependent transport measurements revealed a unique resistance switching mechanism: the modulation of the channel elemental composition, and thus the conductivity, by the cooperative influence of drift, diffusion and thermophoresis, which seem to enable the high switching performance observed. (Miao*, Strachan*, Yang* *et al.*, *Advanced Materials*. DOI: 10.1002/adma.201103379 (2011))

11:27AM Q28.00002 Low-frequency noise properties in nanodiodes, SHAHRIR R. KASJOO, CLAUDIO BALOCCO, ARUN K. SINGH, LINQING Q. ZHANG, YASAMAN ALIMI, AIMIN M. SONG, School of Electrical and Electronic Engineering, University of Manchester, Manchester M13 9PL, United Kingdom — Terahertz (THz) detection by a novel type of unipolar nanodiodes, known as self-switching diodes (SSDs), has recently been demonstrated at room temperature up to 1.5 THz (App. Phys. Lett. Vol. 98, 223501, 2011). Since noise property is also of great importance for THz detection, here we have fabricated thousands of SSDs connected in parallel in order to increase the signal-to-noise ratio. Because of the planar nature of the SSDs, no specific metal interconnects are needed, and hence the device speed and voltage sensitivity are unaffected. We study the low-frequency noise spectra and noise equivalent power (NEP) at room and elevated temperatures. The exceptional possibility for the SSD to have an intrinsic zero threshold voltage enables very low noise at frequencies below 1 kHz, without being much affected by $1/f$ noise. We find that the NEP is comparable to the commercial Schottky diode detector. The activation energy extracted from the temperature dependence is approximately 0.27 eV, which we will compare with the barrier height in the SSD channel as well as the conduction band offset in the InGaAs/InAlAs structure used in this work. We show evidence that the observed $1/f$ noise properties at room and elevated temperatures seem to support Hooge's mobility fluctuation theory.

11:39AM Q28.00003 Understanding the resistive switching in thin-film Ta-O memristors by their d.c. switching characteristics, WEI YI, GILBERTO MEDEIROS-RIBEIRO, FENG MIAO, ILAN GOLDFARB, MAX ZHANG, J. JOSHUA YANG, MATTHEW D. PICKETT, JOHN PAUL STRACHAN, R. STANLEY WILLIAMS, Hewlett-Packard Laboratories, 1501 Page Mill Road, MS1123, Palo Alto, CA 94304, USA, HEWLETT-PACKARD LABORATORIES TEAM — Tantalum oxide (Ta-O) memristor is a promising candidate for resistive switching memory (RRAM) technology as they have demonstrated outstanding features such as high endurance, high speed, and low power. However, the responsible mechanisms remain vague partly due to difficulties in characterizing the amorphous film structure, nanoscale active regions, coupled ionic and electronic transport, and intertwined electrochemical and thermochemical processes. Rich information about Ta-O memristors has been revealed by microscopic structural and chemical characterizations of Ta-O conduction channels combined with temperature-dependent transport measurements. As an alternative approach, we took perspectives from a statistical study of the switching behavior under d.c. excitation. We identified distinctive behaviors in device switching characteristics depending on the chemical compositions of conductance channel, and found close correlations with previous temperature-dependent transport measurements and X-ray photoemission (XPS) characterizations. We were able to gather further insight into the microscopic switching mechanisms based on these observations, revealing the granularity of the switching phenomena.

11:51AM Q28.00004 *In-situ* MBE and ALD deposited HfO₂ on In_{0.53}Ga_{0.47}As¹, W.C. LEE, C.A. LIN, M.L. HUANG, J. KWO, Dept. Phys., Natl Tsing Hua Univ., Hsinchu 30013, Taiwan, Y.H. CHANG, P. CHANG, Dept. Mat. Sci. and Eng., Natl Tsing Hua Univ., Hsinchu 30013, Taiwan, T.D. LIN, M. HONG, Dept. Phys., Natl Taiwan Univ., Taipei 10617, Taiwan — The semiconductor industry is calling for innovative devices offering high performance with low power consumption. High- κ dielectrics/metal gates on high carrier mobility channels are now strong contenders in the post Si CMOS application. Hafnium-based oxide has been employed as the gate dielectric in Si CMOS since 45 nm node and InGaAs is a leading candidate for channel materials. However, reports of HfO₂ on InGaAs are scant, and surface treatments using H₂S or trimethylaluminum are claimed to be required for achieving high quality HfO₂(high- κ)/InGaAs interface. In this work, HfO₂ has been *in-situ* deposited on *n*- and *p*-In_{0.53}Ga_{0.47}As using both molecular-beam-epitaxy (MBE) and atomic-layer-deposition (ALD), without using any interfacial passivation layer or surface treatments. The HfO₂/In_{0.53}Ga_{0.47}As metal-oxide-semiconductor capacitors (MOSCAPs) all exhibit outstanding thermal stabilities ($> 800^{\circ}\text{C}$), low leakage currents ($\sim 10^{-8}$ A/cm² at 1 MV/cm), and good CV characteristics. Moreover, the MOSCAPs have shown spectra of interfacial trap densities (D_{it} 's) with no discernible peaks at mid-gap, confirmed by temperature-dependent conductance method.

¹This work has been supported by Nano National Program (NSC 100-2120-M-007-010) of the NSC of Taiwan, and the AOARD of the US Air Force.

12:03PM Q28.00005 *In-situ* photoemission analyses of ALD-oxide/ $\text{In}_x\text{Ga}_{1-x}\text{As}$ (001) interfaces

, M.L. HUANG, Dept. Phys., Natl Tsing Hua Univ., Hsinchu, Taiwan, Y.H. CHANG, Dept. Mat. Sci. and Eng., Natl Tsing Hua Univ., Hsinchu, Taiwan, T.D. LIN, Dept. Phys., Natl Taiwan Univ., Taipei, Taiwan, W.C. LEE, Dept. Phys., Natl Tsing Hua Univ., Hsinchu, Taiwan, T.H. CHIANG, Dept. Mat. Sci. and Eng., Natl Tsing Hua Univ., Hsinchu, Taiwan, C.A. LIN, H.Y. LIN, Dept. Phys., Natl Tsing Hua Univ., Hsinchu, Taiwan, T.-W. PI, Natl Synchrotron Rad. Res. Ctr, Hsinchu, Taiwan, M. HONG, Dept. Phys., Natl Taiwan Univ., Taipei, Taiwan, J. KWO, Dept. Phys., Natl Tsing Hua Univ., Hsinchu, Taiwan — High- κ dielectrics on high carrier mobility channels, such as $\text{In}_x\text{Ga}_{1-x}\text{As}$, are now being considered for CMOS technology beyond 15 nm node. The initial bonding of high- κ /InGaAs determines the value and the distribution of interfacial density of states (D_{it}) within the $\text{In}_x\text{Ga}_{1-x}\text{As}$ band gap, key to the device performance. In this work, atomic layer deposited (ALD) HfO_2 and Al_2O_3 on MBE-grown $\text{In}_x\text{Ga}_{1-x}\text{As}$ (001) have been *in-situ* and *ex-situ* carried out to investigate the initial stage of interfacial reactions by high resolution photoemission spectroscopy using synchrotron radiation and monochromatic Al K α x-ray sources. Comparing the results with the corresponding electrical measurements (C-V and G-V at various temperatures), Fermi level unpinning in the oxide/ $\text{In}_x\text{Ga}_{1-x}\text{As}$ hetero-structure may be attributed to the exclusion of the As-As and the As-O bonding during the initial interfacial formation.

12:15PM Q28.00006 High Temperature Seebeck Coefficient and Electrical Resistivity of $\text{Ge}_2\text{Sb}_2\text{Te}_5$ Thin Films

, LHACENE ADNANE, FARUK DIRISAGLIK, MUSTAFA AKBULUT, University of Connecticut, YU ZHU, CHUNG LAM, IBM T. J. Watson Research Center, ALI GOKIRMAK, HELENA SILVA, University of Connecticut — Phase-change memory (PCM) is a promising memory technology in which a small volume of a chalcogenide material can be reversibly and rapidly switched between amorphous and crystalline phases by an electrical pulse that brings it above crystallization (~ 150 -200 C) or melting (~ 700 C) temperature. The large temperature levels involved and small dimensions of PCM devices give rise to very large temperature gradients (~ 10 K/nm and higher) which result in strong thermoelectric effects. High-temperature characterization of the temperature-dependent thermoelectric properties of these materials is therefore critical to understand for the operation of these devices but to date there is only limited experimental data available. We have performed simultaneous measurements of Seebeck coefficient and electrical resistance of thin films of GST with different thicknesses, deposited on silicon dioxide, from room temperature to ~ 600 C, under small temperature gradients. Two-point current-voltage (I-V) measurements were performed using a semiconductor parameter analyzer. The resistance of the material and the Seebeck voltage (open-circuit voltage) are calculated from the slope and intercept of the I-V characteristics. The details of the measurements and S(T) and R(T) results for the GST thin film samples will be presented and discussed.

12:27PM Q28.00007 Thermoelectric Effects in Simulations of Phase Change Memory Mushroom Cells

, AZER FARACLAS, GOKHAN BAKAN, ALI GOKIRMAK, HELENA SILVA, University of Connecticut — Phase change memory is a potential candidate for the future of high-speed non-volatile memory, however significant improvements in cell design is crucial for its success in the mainstream market. Due to the asymmetric geometry of phase change mushroom cells and the high temperature gradients generated, thermoelectric effects play a key role in determining energy consumption, cell performance, and reliability. In this study, rotationally symmetric 2D finite element simulations using COMSOL Multiphysics are implemented for GeSbTe (GST). Temperature dependent material parameters (electrical conductivity, thermal conductivity, heat capacity, and Seebeck coefficient) are included in the model for accuracy. Switching the direction of current shows a large change in peak molten volume within the cell, as well as current and power consumption.

12:39PM Q28.00008 Light-controlled plasmon switching using hybrid metal-semiconductor nanostructures¹

, HARI PAUDEL, MICHAEL LEUENBERGER, University of Central Florida — We show a method for the dynamic control over the plasmon resonance frequencies in a hybrid metal-semiconductor nanoshell structure with silver core and TiO_2 coating. We temporarily change the dielectric function of TiO_2 using pump laser pulse operating at bandgap or above. This generates free electron-hole pairs in TiO_2 that alter the dielectric environment for the silver core. The probed surface plasmon frequency lying below bandgap appears to be blue-shifted due to the altered dielectric environment. We calculate the magnitude of the plasmon resonance wavelength shift as a function of electron-hole pair density and obtain shifts up to 126 nm at wavelengths of around 460 nm. Using these results, we propose a model of a light-controlled surface plasmon polariton (SPP) switch.

¹We acknowledge support from NSF (Grant No. ECCS-0901784), AFOSR (Grant No. FA9550-09-1-0450), and NSF (Grant No. ECCS-1128597).

12:51PM Q28.00009 Direct-bandgap infrared light emission from tensilely strained germanium nanomembranes¹

, JOSE SÁNCHEZ-PÉREZ, University of Wisconsin Madison, CICEK BOZTUG, Boston University, FENG CHEN², University of Wisconsin Madison, FAISAL SUDRADJAT, Boston University, DEBORAH PASKIEWICZ, R.B. JACOBSON, University of Wisconsin Madison, ROBERTO PAIELLA, Boston University, MAX LAGALLY, University of Wisconsin Madison — Silicon, germanium, and related alloys, which provide the leading materials platform of electronics, are extremely inefficient light emitters because of their indirect fundamental energy bandgap. This basic materials property has so far hindered the development of group-IV photonic active devices, including diode lasers, thereby significantly limiting our ability to integrate electronic and photonic functionalities at the chip level. We show that Ge nanomembranes can be used to overcome this materials limitation. Theoretical studies have predicted that tensile strain in Ge lowers the direct energy bandgap relative to the indirect one. We demonstrate [1] that mechanically stressed nanomembranes allow for the introduction of sufficient biaxial tensile strain to transform Ge into a direct-bandgap, efficient light-emitting material that can support population inversion and therefore provide optical gain.

1:03PM Q28.00010 A Tunable Terahertz Detector Based On Self Assembled Plasmonic Structure on a GaAs 2DEG

, CHEJIN BAE, DEEPU GEORGE, ROHIT SINGH, ANDREA MARKELZ, University at Buffalo (SUNY) Department of Physics — The use of tunable gated gratings on 2DEG structure has been well known methods for compact frequency sensitive THz detection based on the resonant absorption of the 2D Plasmon. The resonant frequency is dependent on system dimension and the tunability of that dimension by depletion gating. Here we attempt to improve detector sensitivity, tunability and remove polarization dependence through the development of a gated grid design. To satisfy the requirement for imaging applications of device dimensions on the order of < 1 micron over a detector area of 4 mm^2 , we have fabricated gated grid plasmonic structure on 2DEG material by using nanosphere self-assembly lithography. This fabrication method has not been widely developed for III-V processing but allows us to achieve large area sensitive detectors with tunability in the 1-4 THz range. In this paper we will discuss the characterization of the devices as a function of gate bias, magnetic field, and temperature using FTIR and THz time domain measurements.

1:15PM Q28.00011 Time-resolved second harmonic generation study of buried semiconductor heterointerfaces using soliton-induced transparency, Y.D. GLINKA¹, Department of Physics, University of Texas at Austin, Austin, Texas 78712, USA, N.H. TOLK, Department of Physics and Astronomy, Vanderbilt University, Nashville, Tennessee 37235, USA, J.K. FURDYNA, Department of Physics, University of Notre Dame, Notre Dame, Indiana 46556, USA — The transient second harmonic generation (SHG) and linear optical reflectivity (LOR) signals measured simultaneously in reflection from GaAs/GaSb/InAs and GaAs/GaSb heterostructures revealed a new mechanism for creating self-induced transparency in narrow bandgap semiconductors at low temperatures, which is based on the dual-frequency electro-optic soliton propagation. The mechanism takes account of the photo-Dember field solitary wave, which traps both the fundamental and SHG pulses, slowing their velocity down to that of the solitary wave. The trapped light pulses maintain the amplitude of the solitary wave and hence create a condition, at which the self-reinforcing nonlinear optical polarization (dual-frequency electro-optic soliton) can propagate through the semiconductor. This allows the ultrafast carrier dynamics at buried semiconductor heterointerfaces to be studied.

1:27PM Q28.00012 Room temperature ballistic transport in InSb quantum well structures, ADAM GILBERTSON, LESLEY COHEN, Imperial College, PHIL BUCKLE, Cardiff University, TIM ASHLEY, Warwick University, STUART SOLIN, Washington University in St. Louis, ANDOR KORMANYOS, COLIN LAMBERT, Lancaster University — We report significant advancements in InSb/AlInSb quantum well (QW) heterostructures for room temperature nanoelectronic applications. InSb/AlInSb heterostructures have phenomenally high room temperature mobility but display intrinsic parallel conduction in the buffer layer limiting exploitation for nanostructured devices where deep isolation etch processing is impractical. We demonstrate a strategy to reduce the parasitic conduction by the insertion of a pseudomorphic barrier layer of wide-band-gap alloy below the QW.¹ Mesoscopic geometric nanocrosses fabricated from such material clearly demonstrate ballistic transport at room temperature, as evidenced by very significant negative bend resistance (NBR). We have studied the interplay between sidewall and bulk scattering at 300K in relation to quantum calculations. DC measurements in the non-equilibrium (hot carrier) regime reveal that electrons remain ballistic at current densities in excess of 10^6 A/cm².

1:39PM Q28.00013 Spectral and Spatial Response of Sulfur-Hyperdoped n+/p Silicon Photodiodes¹, DAVID HUTCHINSON, Rensselaer Polytechnic Institute, DANIEL RECHT, Harvard University, JOSEPH SULLIVAN, Massachusetts Institute of Technology, JEFFREY WARRENDER, US Army - ARDEC, Benet Laboratories, MICHAEL AZIZ, Harvard University, TONIO BUONASSISI, Massachusetts Institute of Technology, PETER PERSANS, Rensselaer Polytechnic Institute — Pulsed laser melting of implanted silicon can enable doping well above equilibrium concentrations. Sulfur doping leads to a deep donor state that may form an impurity band at high enough concentrations. Photodiodes formed from sulfur-hyperdoped n+ layers on a p-type wafer have shown external quantum efficiency of much greater than 100%, as well as enhanced infrared response. In this paper we report on optoelectronic characterization of diodes prepared by implantation of $10^{15} - 10^{16}$ sulfur/cm² into a p-type wafer, followed by nanosecond pulsed laser melting and recrystallization. Experimental results from wavelength-dependent diode response, spatial quantum efficiency mapping, intensity dependent efficiency, and current-voltage techniques will be reported. We will also discuss potential models for the observed behavior.

1:51PM Q28.00014 The mesoscopic chaotic cavity as a rectifying heat engine, ANDREW JORDAN, University of Rochester, BJÖRN SOTHMANN, University of Geneva, RAFAEL SÁNCHEZ, Instituto de Ciencia de Materiales de Madrid, MARKUS BUTTIKER, University of Geneva — We present an exactly solvable model of a mesoscopic heat engine that works using the principle of rectifying thermal fluctuations applied to a nonlinear system. The system is a chaotic mesoscopic cavity where the contact transmission to leads is energy-dependent. This energy-dependence is generic in mesoscopic conductors, and leads to an intrinsic nonlinearity. The cavity is coupled capacitively to another conductor, held at a different temperature. The nonlinear cavity rectifies the thermal fluctuations, leading to a hot spot rectified electrical current that is proportional to the asymmetry in the energy-dependence of the contacts, and to the temperature difference. We will discuss the maximum power produced by the system, as well as the efficiency of the engine by comparing it to the heat current that passes between the coupled systems. Possible practical energy-harvesting applications will be proposed.

2:03PM Q28.00015 Thermal properties of CuGaS₂ from first principles¹, ALDO H. ROMERO, CINVESTAV, Unidad Queretaro, Mexico, MANUEL CARDONA, REINHARD KREMER, MPI, Stuttgart, ALEXANDER SCHINDLER, NETZSCH-Geratebau GmbH, ALFONSO MUÑOZ, Departamento de Física, Universidad de la Laguna, Spain — We have investigated in the past the specific heats of monatomic and binary semiconductors and their dependence on temperature and isotopic mass, both experimentally and theoretically. The theoretical calculations were performed *ab initio* with LDA exchange correlations. We are at present carrying over these investigations to ternary materials, in particular to those with chalcopyrite structure. We present here results involving the dependence of the specific heat and other physical properties (lattice parameters, volume thermal expansion, phonon dispersion) of the chalcopyrite CuGaS₂ on temperature and on the isotopic masses of the three constituent atoms. Particular emphasis is paid to the maxima of C_p/T^3 found at low temperatures which correspond to the deviation of Debye's law related to transverse acoustic phonons near the zone boundary. The calculations were performed with the ABINIT and VASP codes within the local density approximation for exchange and correlation. The results are shown to be in excellent agreement with the experimental data. Correlation with similar compounds such as CuAlS₂ and CuInS₂ is discussed.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q29 GQI: Focus Session: Topologically Protected Qubits II 259A

11:15AM Q29.00001 Topological superconducting states and protected qubit manipulations¹, SUMANTA TEWARI, Physics and Astronomy, Clemson University, Clemson, SC 29634 — Topological superconducting states supporting Majorana fermion excitations have been recently proposed as platforms for topological quantum computation. Of particular importance are semiconductor-superconductor and topological insulator-superconductor heterostructures, which have been shown to support Majorana fermions at order parameter defects under appropriate external conditions. Here I will focus on topologically non-trivial properties of two-dimensional semiconductors and one-dimensional quantum wires placed adjacent to superconductors, and discuss the possible protected qubit manipulations that may eventually lead to topological quantum computation.

11:51AM Q29.00002 Majorana Zero Modes in 1D Quantum Wires Without Long-Ranged Superconducting Order, LUKASZ FIDKOWSKI, ROMAN LUTCHYN, CHETAN NAYAK, Microsoft Station Q, MATTHEW FISHER, University of California, Santa Barbara — We show that long-ranged superconducting order is not necessary to guarantee the existence of Majorana fermion zero modes at the ends of a quantum wire. We formulate a concrete model which applies, for instance, to a semiconducting quantum wire with strong spin-orbit coupling and Zeeman splitting coupled to a wire with algebraically-decaying superconducting fluctuations. We solve this model by bosonization and show that it supports Majorana fermion zero modes. We argue that a large class of models will also show the same phenomenon. We discuss the implications for experiments on spin-orbit coupled nanowires coated with superconducting film and for LaAlO₃/SrTiO₃ interfaces.

12:03PM Q29.00003 Coulomb stability of the 4π -periodic Josephson effect of Majorana fermions, FABIAN HASSLER, Institute for Quantum Information, RWTH Aachen University, D-52056 Aachen, Germany, BERNARD VAN HECK, ANTON R. AKHMEROV, C.W.J BEENAKKER, Instituut-Lorentz, Universiteit Leiden, P.O. Box 9506, 2300 RA Leiden, The Netherlands — The Josephson energy of two superconducting islands containing Majorana fermions is a 4π -periodic function of the superconducting phase difference. If the islands have a small capacitance, their ground state energy is governed by the competition of Josephson and charging energies. We calculate this ground state energy in a ring geometry, as a function of the flux Φ enclosed by the ring, and show that the dependence on the Aharonov-Bohm phase $2e\Phi/\hbar$ remains 4π -periodic regardless of the ratio of charging and Josephson energies—provided that the entire ring is in a topologically nontrivial state. If part of the ring is topologically trivial, then the charging energy induces quantum phase slips that restore the usual 2π -periodicity [B. van Heck, F. Hassler, A. R. Akhmerov, and C. W. J. Beenakker, Phys. Rev. B **84**, 180502(R) (2011)].

12:15PM Q29.00004 Unconventional Josephson signatures of Majorana bound states, LIANG JIANG, DAVID PEKKER, GIL REFAEL, Department of Physics, Caltech, JASON ALICEA, Department of Physics and Astronomy, University of California, Irvine, YUVAL OREG, Department of Condensed Matter Physics, Weizmann Institute of Science, FELIX VON OPPEN, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin — A junction between two topological superconductors containing a pair of Majorana fermions exhibits a ‘fractional’ Josephson effect, 4π periodic in the superconductors’ phase difference. An additional fractional Josephson effect, however, arises when the Majoranas are spatially separated by a superconducting barrier. This new term gives rise to a set of Shapiro steps which are essentially absent without Majorana modes and therefore provides a unique signature for these exotic states. Other new signatures associated with Majorana fermions will also be discussed.

12:27PM Q29.00005 Signature of Majorana Fermions in Charge Transport in Semiconductor Nanowires¹, CHUNLEI QU, YONGPING ZHANG, LI MAO, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, WA 99164 — We investigate the charge transport in a semiconductor nanowire that is subject to a perpendicular magnetic field and in partial contact with an s-wave superconductor. We find that Majorana fermions, existing at the interface between superconducting and normal sections of the nanowire within certain parameter region, can induce resonant Andreev reflection of electrons at the interface, which yields a zero energy peak in the electrical conductance of the nanowire. The width of the zero energy conductance peak for different experimental parameters is characterized. While the zero energy peak provides a signature for Majorana fermions in one dimensional nanowires, it disappears in a two-dimensional semiconductor thin film with the same experimental setup because of the existence of other edge states in two dimensions. The proposed charge transport experiment may provide a simple and experimentally feasible method for the detection of Majorana fermions in semiconductor nanowires.

¹This work is supported by DARPA-MTO (FA9550-10-1-0497), DARPA-YFA (N66001-10-1-4025), and NSF-PHY (1104546).

12:39PM Q29.00006 Searching for Majorana Zero-Energy Modes in Semiconductor Nanowires, PETER O'MALLEY, PEDRAM ROUSHAN, BORZOYEH SHOJAEI, UC Santa Barbara, ROMAN LUTCHYN, Microsoft Station Q, CHRIS PALMSTROM, JOHN MARTINIS, UC Santa Barbara — Majorana fermions are proposed elementary particles with the unique property of being their own antiparticle, whose discovery remains elusive. Because of their non-Abelian statistics, Majorana fermions provide a promising opportunity to realize fault-tolerant topological quantum computation. Recently, semiconductor nanowires have been proposed as a possible platform for realizing Majorana physics in solid state systems. An s-wave superconductor inducing the proximity effect in a one-dimensional semiconductor nanowire would create chiral p-wave superconductivity in the nanowire; this superconductor would have Majorana modes as zero-energy excitations. We use nanofabrication techniques to create such nanowires out of MBE-grown two-dimensional electron gas formed in III-V semiconductor heterostructures. We present measurements which show the promise of this approach to creating and controlling Majorana excitations.

12:51PM Q29.00007 Majorana fermions in superconducting helical magnets, IVAR MARTIN, LANL, ALBERTO MORPURGO, University of Geneva — In a variety of rare-earth based compounds singlet superconductivity coexists with helical magnetism. Here we demonstrate that surfaces of these system are expected to generically host a finite density of zero-energy Majorana modes. When confined to a wire geometry, a discrete number of Majorana modes can be isolated, in close analogy with the Rashba superconductors proposed recently as a framework for topological quantum computing. In contrast to the latter systems, however, the larger characteristic energy scales for superconductivity and magnetism, as well as the lack of need for fine-tuning, make helical magnetic superconducting compounds favorable for the observation and experimental investigation of Majorana fermions.

1:03PM Q29.00008 Stability of Majorana fermions in proximity-coupled topological insulator nanowires¹, ASHLEY COOK, MARCEL FRANZ, University of British Columbia — It has been shown previously [1] that a finite-length topological insulator nanowire, proximity-coupled to an ordinary bulk s-wave superconductor and subject to a longitudinal applied magnetic field, realizes a one-dimensional topological superconductor with an unpaired Majorana fermion localized at each end of the nanowire. Here we show that the unpaired Majorana fermions persist in this system for any value of the chemical potential inside the bulk band gap of order 300 meV in Bi₂Se₃, and, remarkably, also outside this gap in smaller domains, by computing the Majorana number. From this calculation, we also show that the unpaired Majorana fermions persist when the magnetic flux through the nanowire cross-section deviates significantly from half flux quantum. Lastly, we demonstrate that the unpaired Majorana fermions persist in strongly disordered wires with fluctuations in the on-site potential ranging in magnitude up to the size of the bulk band gap. These results suggest this solid-state system should exhibit the elusive Majorana particles under conditions accessible enough for their long sought-after experimental realization.

1:15PM Q29.00009 Josephson current in finite-length nanowire SNS junctions with Majorana fermions, RAMON AGUADO, ELSA PRADA, ICM-CONICET, Consejo Superior de Investigaciones Científicas, PABLO SAN JOSE, ICM-CONICET, Consejo Superior de Investigaciones Científicas — The dc Josephson effect (JE) through infinite-length junctions of one-dimensional topological superconductors exhibits an anomalous 4π periodic phase (ϕ) dependence which originates from a parity-protected level crossing of zero-energy Majorana bound states (MBS) at $\phi = \pi$. This “fractional” JE provides an important experimental detection tool for MBS. In this talk, I will discuss the JE in more realistic SNS junctions of arbitrary transparency and when both the normal and the nanowire regions are of finite length, namely beyond the short-junction and infinite topological superconductor limits. In general, the spectrum of Andreev bound states can become rather intricate and dense as opposed to the infinite-length case. Moreover, the low-energy spectrum around $\phi = \pi$ shows always anticrossings, originated from hybridization of four MBS, which may preclude the experimental observation of the fractional JE. At finite bias voltages, Landau-Zener dynamics involving the MBS and quasi-continuum Andreev levels gives rise to a nontrivial ac Josephson current. Interestingly, the ac current phase diagram as a function of the Josephson frequency/normal transmission shows fractional JE regions which are tunable through bias/gate voltages.

1:27PM Q29.00010 Detecting a Majorana-Fermion Zero Mode Using a Quantum Dot¹, DONG E. LIU, HAROLD U. BARANGER, Duke University — We propose an setup for detecting a Majorana zero mode consisting of a spinless quantum dot coupled to the end of a p-wave superconducting nanowire [1]. The conductance through the dot is monitored by adding two external leads. We find that the Majorana bound state at the end of the wire strongly influences the conductance through the quantum dot: driving the wire through the topological phase transition causes a sharp jump in the conductance by a factor of 1/2. In the topological phase, the zero temperature peak value of the dot conductance (i.e. on resonance and symmetric coupling) is $e^2/2h$. In contrast, if the wire is in its trivial phase, the peak is e^2/h , or if a regular fermionic zero mode occurs, the conductance is 0. We also consider coupling the dot to both ends of the wire (two MBS), with a magnetic flux Φ through the loop. The conductance as a function of phase shows peaks at $\Phi/\Phi_0 = (2n+1)\pi$ which can be used to tune Flensberg’s qubit system [PRL (2011)] to the energy degeneracy point.

1:39PM Q29.00011 Majorana chain coupled to a microwave cavity, MIRCEA TRIF, YAROSLAV TSERKOVNYYAK, Department of Physics and Astronomy, University of California, Los Angeles, California 90095, USA — We study the Majorana end-states in a one-dimensional Kitaev model in the presence of a microwave cavity. We analyze both the resonant and off-resonant coupling to the cavity for different cavity states. In the resonant regime, we find that the topology of the system can be modified depending on the number of photons in the cavity, while in the off-resonant regime (large detuning), the cavity could be used to detect the topological transition from a non-trivial to trivial state, being thus an optical alternative to the transport-based detection of the transition point. We also analyze the effects of the coupling to the cavity on the braiding of the emerging Majoranas.

1:51PM Q29.00012 Majorana modes in time-reversal invariant s-wave topological superconductors, SHUA DENG, LORENZA VIOLA, Dartmouth College, GERARDO ORTIZ, University of Indiana, Bloomington — We present a time-reversal invariant s-wave superconductor supporting Majorana edge modes. The multi-band character of the model together with spin-orbit coupling are key to realizing such a topological superconductor. We characterize the topological phase diagram by using a partial Chern number sum, and show that the latter is physically related to the parity of the fermion number of the time-reversal invariant modes. By taking the self-consistency constraint on the s-wave pairing gap into account, we also establish the possibility of a direct topological superconductor-to-topological insulator quantum phase transition.

2:03PM Q29.00013 Majorana Fermions in Disordered Quasi-One-Dimensional Topological Superconductors, ANDREW POTTER, PATRICK LEE, MIT — Majorana fermions have long been predicted to emerge in certain quantum Hall states and other naturally occurring p-wave superconductors. However, these materials are quite delicate and consequently the experimental realization of Majorana fermions remains elusive. The possibility of engineering 1D networks of topological superconducting wires from conventional materials offers a promising alternative route to realize Majorana fermions and probe their predicted non-Abelian statistics. In practice, it is impossible to fabricate perfectly clean and strictly one-dimensional structures; how do these non-idealities affect the proposed Majorana states? This talk will show that Majorana end states are robust away from the strict 1D limit, so long as the sample width is not much larger than the superconducting coherence length. The effects of disorder are potentially more severe, as impurity scattering is generally pair-breaking and tends to suppress the gap protecting the Majorana modes. Finally, we propose new candidate materials and geometries that greatly simplify the experimental setup and mitigate the harmful effects of disorder.

Wednesday, February 29, 2012 11:15AM - 2:15PM –
Session Q30 GQI: Focus Session: Superconducting Qubits: Architecture, Tunable, and Static Coupling 259B

11:15AM Q30.00001 Coupling superconducting qubits and resonators, JOEL STRAND, Syracuse University — The performance of superconducting qubits has evolved rapidly in recent years, with coherence times now often measured in tens of microseconds. This makes superconducting qubits a promising candidate for a scalable quantum computing architecture and for modeling quantum systems. To realize this potential, consideration must be given to coupling multiple qubits to a system of microwave resonators in a way that balances coherence times, control and readout times, crosstalk, and space constraints. We compare three methods of coupling qubits to resonators: inductive coupling through a shared kinetic inductance with the resonator, capacitive coupling to a voltage antinode, and coupling to a three-dimensional superconducting cavity. We will also present designs and measurements of samples incorporating both inductively and capacitively coupled qubits on the same coplanar resonator. Lastly, we discuss a three-qubit/two-resonator system with one qubit bridging the two resonators that could serve as the building block of a large-scale architecture.

11:51AM Q30.00002 Inductive coupling to the fluxonium qubit¹, N.A. MASLUK, A. KAMAL, I. POP, Z.K. MINEV, Yale University, V.E. MANUCHARYAN, Harvard University, J. KOCH, Northwestern University, L.I. GLAZMAN, M.H. DEVORET, Yale University — Fluxonium is a highly anharmonic artificial atom, which utilizes an inductance formed by an array of large Josephson junctions to shunt the junction of a Cooper-pair box. The first excited state transition frequency is widely tunable with flux, and due to interactions of transitions to the second excited state with the readout cavity, a dispersive readout is possible over the entire five octave range. Previous fluxonium samples relied on a capacitive coupling to the readout cavity, but there is evidence that dielectric losses in these capacitors contributes significantly to relaxation [1]. We present a new method of coupling to the cavity through a mutual inductance, reducing relaxation through dielectric loss.

12:03PM Q30.00003 A dc SQUID Phase Qubit with Controlled Coupling to the Microwave Line¹, R.P. BUDOYO, B.K. COOPER, JQI and CNAM, University of Maryland, V. ZARETSKEY, Laboratory for Physical Sciences and University of Maryland, C.J. BALLARD, JQI and CNAM, University of Maryland, Z. KIM, JQI, University of Maryland, H. KWON, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, JQI and CNAM, University of Maryland — We have designed and fabricated a Al/AIO_x/Al dc SQUID phase qubit on a sapphire substrate with a qubit junction area of 0.4 μm^2 . The qubit junction is shunted with a 1 pF interdigitated capacitor, and is isolated from the bias leads by an LC filter and an inductive isolation network using a larger Josephson junction. Our previous device (A. Przybysz *et al.*, IEEE Trans. on Appl. Supercond., 2011) with similar parameters had its relaxation time T_1 limited by coupling to the microwave line. To reduce this coupling, we adopted a coplanar stripline design and verified the coupling strength using finite element model microwave simulations. We will discuss our design, the microwave simulations, estimates for the overall coherence time due to losses and noise from various sources, the device fabrication process, and progress towards testing the device.

¹Acknowledgement: LPS, CNAM, JQI

12:15PM Q30.00004 Large tunable inductance of the decorated Josephson chain, IVAN SADOVSKYY, MATTHEW BELL, LEV IOFFE, Rutgers University, ALEXEI KITAEV, California Institute of Technology, MICHAEL GERSHENSON, Rutgers University — We discuss the new design of a tunable superconductive inductance made from the decorated frustrated Josephson junction chains frustrated by magnetic field. We show that for the optimal choice of parameters the inductance of this chain varies in a very wide range as a function of the magnetic field. The resulting plasma frequency may exceed the value of quantum resistance, $\sqrt{L/C} \gg h/(2e)^2$ that characterizes superinductance. The important distinction of this design from the chain of dc-SQUIDs loops is the absence of phase slips at all magnetic fields. We present the results of the extensive numerical simulations that confirm these expectations.

12:27PM Q30.00005 Driven dynamics of a qubit tunably coupled to a harmonic oscillator¹, SIMON GUSTAVSSON, JONAS BYLANDER, FEI YAN, POL FORN-DIAZ, Massachusetts Institute of Technology, VLAD BOLKHOVSKY, DANIELLE BRAJE, STEVEN SPECTOR, BEN TUREK, PAUL B. WELANDER, MIT Lincoln Lab, FUMIKI YOSHIHARA, NEC, DAVID. G. CORY, University of Waterloo, YASUNOBU NAKAMURA, NEC, WILLIAM D. OLIVER, Massachusetts Institute of Technology, MIT Lincoln Lab — We have investigated the driven dynamics of a superconducting flux qubit that is tunably coupled to a microwave resonator. We find that the qubit experiences an additional oscillating field mediated by off-resonant driving of the resonator, leading to unanticipated, strong modifications of the qubit Rabi frequency. Low-frequency noise in the coupling parameter translates to an effective noise in the amplitude of the drive field, causing a reduction of the coherence time during driven evolution. The noise can be mitigated with the rotary-echo pulse sequence, which, for driven systems, is analogous to the Hahn-echo sequence.

12:39PM Q30.00006 Phase gate operation on a flux qubit via the readout SQUID line¹, X.Y. JIN, S. GUSTAVSSON, J. BYLANDER, F. YAN, Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, F. YOSHIHARA, S. NAKAMURA, The Institute of Physical and Chemical Research (RIKEN), Wako, Saitama 351-0198, Japan, W.D. OLIVER, MIT Lincoln Laboratory, 244 Wood Street, Lexington, Massachusetts 02420 — Detuning a superconducting qubit from its rotating frame is one means to implement a phase gate operation. For superconducting flux qubits, this detuning can be realized by changing the magnetic flux threading the qubit loop, e.g., by the mutual coupling from a nearby microwave antenna. In this work, we demonstrate an alternative approach: we implement a phase gate by pulsing a current through the readout DC SQUID. While the DC SQUID acts as a qubit flux sensor for readout, we in turn may use it as an actuator to impose the phase-gate flux shift. Using this pulsed current approach, we demonstrated Ramsey-type free-induction with more than 20 oscillation periods. We also studied the impact of the first phase gate on subsequent, sequential phase gates.

¹This work is sponsored by the Department of the Air Force under contract number FA8721-05-C-0002. Opinions, interpretations, conclusions, and recommendations are those of the author(s) and are not necessarily endorsed by the United States government.

12:51PM Q30.00007 Progress towards a metastable superconducting qubit¹, ANDREW KERMAN, WILLIAM OLIVER, VLADIMIR BOLKHOVSKY, MARK GOUKER, MIT Lincoln Laboratory — We will report on progress towards the demonstration of a metastable RF SQUID (MRFS) qubit, which has the potential to exhibit excited-state lifetimes many orders of magnitude longer than present-day superconducting qubits, while retaining long enough coherence times to allow gate error rates as low as $\sim 10^{-5}$. These properties result from the two main characteristics of the MRFS qubit: (i) its two lowest levels are essentially macroscopically distinct persistent-current states, which can be strongly decoupled from high-frequency electromagnetic fluctuations (in contrast to most superconducting qubits whose levels are approximately those of a nonlinear LC oscillator and are thus strongly coupled); and (ii) its extremely large inductance makes it only weakly sensitive to low-frequency magnetic flux noise.

¹This work is sponsored under Air Force Contract Number FA8721-05-C-0002. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the United States Government.

1:03PM Q30.00008 Quantum gates by qubit frequency modulation in circuit QED, FELIX BEAUDOIN, Universite de Sherbrooke, MARCUS P. DA SILVA, BLAKE R. JOHNSON, THOMAS A. OHKI, ZACHARY DUTTON, Disruptive Information Processing Technologies Group, Raytheon BBN Technologies, ALEXANDRE BLAIS, Universite de Sherbrooke — Several types of two-qubit gates have been realized experimentally in circuit QED. These are based, for example, on tuning the pair of qubits in resonance with each other [Majer, Nature 449, 443-447 (2007)] or on a microwave pulse on one qubit at the transition frequency of a second qubit [Chow, Phys. Rev. Lett. 107, 080502 (2011)]. Another realization is based on a sequence of blue-sideband transitions generated by microwave pulses [Leek, Phys. Rev. B 79, 180511(R) (2009)]. Here, we propose a different approach relying on oscillations of the qubit frequency using a flux-bias line. We explain how frequency modulation leads to tunable qubit-resonator and qubit-qubit interactions. We also show how this form of quantum control leads to faster (first-order) sideband transitions and consider applications to two-qubit gates.

1:15PM Q30.00009 Transmon qubit coupled to a quasi-lumped element resonator, B. SURI, S. NOVIKOV, V. ZARETSKEY, Dept. of Physics, University of Maryland, College Park, B.S. PALMER, Lab for Physical Sciences, College Park, Maryland, F.C. WELLSTOOD, JQI, CNAM, Dept. of Phys, Univ of MD, College Park — We report on the design, fabrication and measurement of an Al/AIO_x/Al transmon qubit coupled to a quasi-lumped element superconducting resonator. Our resonator, which has a resonant frequency of ≈ 5.4 GHz, and a loaded quality factor $Q_l \approx 30,000$ is, in turn, coupled to a transmission line. The qubit is designed to have $E_J/E_C > 30$ to significantly decrease the sensitivity to low-frequency charge noise. The coupling of the qubit to the resonator is designed to be $g/2\pi > 100$ MHz. We report and discuss preliminary spectroscopic measurements and coherence measurements of the qubit.

1:27PM Q30.00010 Fast, coherent control of the tunable coupling qubit, SRIKANTH SRINIVASAN, ANTHONY HOFFMAN, YANBING LIU, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, JAY GAMBETTA, IBM T.J. Watson Research Center, Yorktown Heights, New York 10598, ANDREW HOUCK, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544 — We present results of time domain measurements on a tunable coupling qubit (TCQ) coupled to a superconducting coplanar waveguide resonator. The TCQ has the benefit of independently tunable qubit frequency and cavity-qubit coupling. We show that the TCQ's frequency and coupling can be dynamically controlled in tens of nanoseconds by using two on-chip flux control lines. Using this dynamic control, Rabi oscillations were measured at various coupling strengths showing that the coupling can be reduced by a factor greater than 1500. To measure qubit coherence at low coupling, the TCQ was tuned to a high coupling region, excited by a synchronized pi-pulse and then returned to the zero coupling region where the qubit state was measured. Coherence times of several microseconds were measured and are comparable to other superconducting qubits

1:39PM Q30.00011 Transferring the state of a quantum register to a single oscillator: a simple circuit verses numerical optimization¹, KURT JACOBS, XIAOTING WANG, University of Massachusetts at Boston, FREDERICK STRAUCH, Williams College — We consider the problem of swapping a quantum state between a register of qubits and a single quantum oscillator. We design a mesoscopic quantum circuit to do this, using an off-resonant interaction, based on the concept of coherent feedback control. We consider an explicit realization of this circuit, and perform simulations of its performance. We then take a different approach, in which we couple the register directly to the resonator, including inter-qubit couplings and local controls, and use numerical optimization to search for a control protocol that will achieve the swap with very high fidelity. Our results show that the protocols found using numerical searches are superior in speed and fidelity to the manually-designed circuit. We also explore how the time and complexity of the protocols increases with the problem size.

1:51PM Q30.00012 Gradiometric persistent current flux qubit with tunable tunnel coupling¹, F. DEPPE, M. SCHWARZ, J. GOETZ, A. BAUST, M. HAEBERLEIN, E. HOFFMANN, E.P. MENZEL, F. WULSCHNER, L. ZHONG, A. MARX, R. GROSS, Walther-Meissner-Institute and TU Munich, Garching, Germany — The persistent current flux qubit is a Josephson junction based superconducting circuit exhibiting a strong anharmonicity in combination with excellent coherence times of more than 10 μ s. However, quantum coherence decreases drastically away from an optimal point and a controlled design of the transition frequency at this point is demanding with respect to fabrication stability. Here, we present the spectroscopic analysis of a gradiometric flux qubit, where the tunnel coupling can be tuned from a few hundreds of Megahertz to several Gigahertz.

¹Supported by the DFG via SFB 631 and by the German Excellence Initiative via NIM.

2:03PM Q30.00013 Large dispersive shift in superconducting flux qubit, TSUYOSHI YAMAMOTO, NEC Corporation, KUNIHIRO INOMATA, RIKEN, YASUNOBU NAKAMURA, JAW-SHEN TSAI, NEC Corporation — We study dispersive readout in superconducting flux qubits which are capacitively coupled to a superconducting cavity with ~ 10 GHz resonant frequency f_r . To discriminate the state of the qubit precisely, large magnitude of the dispersive shift χ is desirable. For the two-level system, χ is given by g^2/Δ where g is the coupling strength and Δ is the detuning between the qubit and the cavity. For the multilevel system such as superconducting qubits, however, this formula is modified due to the contributions from higher levels [1]. It has been pointed out that if f_r lies between 01 and 12 transition frequencies of the qubit (f_{01} and f_{12} , respectively), $|\chi|$ becomes large because of constructive contributions from different levels [1]. Our flux qubit has $f_{01} = 5$ GHz and $f_{12} = 15$ GHz at the optimal flux bias, thus satisfying this condition. Moreover, because of the large anharmonicity ($|f_{12} - f_{01}|$) of the flux qubit, we can easily make g as large as ~ 100 MHz, while staying in the deep dispersive limit. Both of these enhance $|\chi|$ and we have obtained χ of 80 MHz at the optimal flux bias, which agrees well with the prediction by the energy band calculation. [1] J. Koch et al., PRA 76, 042319 (2007)

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q31 GMAG DMP: Focus Session: Topological Insulators - Edge States 260

11:15AM Q31.00001 Electrical control of spin in topological insulators, KAI CHANG, SKLSM, Institute of Semiconductors, Chinese Academy of Science, Beijing, China — All-electrical manipulation of electron spin in solids becomes a central issue of quantum information processing and quantum computing. The many previous proposals are based on spin-orbit interactions in semiconductors. Topological insulator, a strong spin-orbit coupling system, make it possible to control the spin transport electrically. Recent calculations proved that external electric fields can drive a HgTe quantum well from normal band insulator phase to topological insulator phase [1]. Since the topological edge states are robust against local perturbation, the controlling of edge states using local fields is a challenging task. We demonstrate that a p-n junction created electrically in HgTe quantum wells with inverted band structure exhibits interesting intraband and interband tunneling processes. We find a perfect intraband transmission for electrons injected perpendicularly to the interface of the p-n junction. The opacity and transparency of electrons through the p-n junction can be tuned by changing the incidence angle, the Fermi energy and the strength of the Rashba spin-orbit interaction (RSOI). The occurrence of a conductance plateau due to the formation of topological edge states in a quasi-one-dimensional p-n junction can be switched on and off by tuning the gate voltage. The spin orientation can be substantially rotated when the samples exhibit a moderately strong RSOI [2]. An electrical switching of the edge-state transport can also be realized using quantum point contacts in quantum spin Hall bars. The switch-on/off of the edge channel is caused by the finite size effect of the quantum point contact and therefore can be manipulated by tuning the voltage applied on the split gate [3,4]. The magnetic ions doped on the surface of 3D TI can be correlated through the helical electrons. The RKKY interaction mediated by the helical Dirac electrons consists of the Heisenberg-like, Ising-like, and Dzyaloshinskii-Moriya (DM)-like terms, which can be tuned by changing the gate voltage. It provides us a new way to control surface magnetism electrically. The gap opened by doped magnetic ions can lead to a short-range Bloembergen-Rowland interaction. The competition among the Heisenberg, Ising, and DM terms leads to rich spin configurations and an anomalous Hall effect on different lattices [4]. There are many proposals for quantum computation scheme are based on the spin in semiconductor quantum dots. Topological insulator quantum dots display a very different behavior with that of conventional semiconductor quantum dots [5]. In sharp contrast to conventional semiconductor quantum dots, the quantum states in the gap of the HgTe QD are fully spin-polarized and show ring-like density distributions near the boundary of the QD and optically dark. The persistent charge currents and magnetic moments, i.e., the Aharonov-Bohm effect, can be observed in such a QD structure. This feature offers us a practical way to detect these exotic ring-like edge states by using the SQUID technique.

11:51AM Q31.00002 Conductance of the Quantum Spin Hall Edge in HgTe Quantum Wells ,

VIVEK VENKATACHALAM, SEAN HART, Harvard University, MATHIAS MÜHLBAUER, CHRISTOPH BRÜNE, LAURENS MOLENKAMP, Würzburg University, AMIR YACOBY, Harvard University — A two-dimensional electron system with band inversion due to spin-orbit interactions can support counterpropagating edge channels, each with one unit of conductance. Unlike the conventional quantum Hall effect, however, these channels can back scatter into each other in the presence of magnetic impurities (or other time-reversal breaking scattering sources). With topgates, we can create 1 μm edges of these QSH states and characterize their transmission. In some regions, we are able to see the quantized conductance that is expected of the QSH effect. In other regions, we see a higher resistance corresponding to a nonzero amount of scattering in the channel.

12:03PM Q31.00003 Inelastic electron backscattering in a generic helical edge channel ,

THOMAS L. SCHMIDT, Department of Physics, Yale University, 217 Prospect Street, New Haven, CT 06520, USA and Department of Physics, University of Basel, Switzerland, STEPHAN RACHEL, Department of Physics, Yale University, 217 Prospect Street, New Haven, CT 06520, USA, FELIX VON OPPEN, Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany, LEONID I. GLAZMAN, Department of Physics, Yale University, 217 Prospect Street, New Haven, CT 06520, USA — We calculate the low-temperature conductance of a generic one-dimensional helical liquid which exists at the edge of a two-dimensional topological insulator (quantum spin Hall insulator). In a generic case, the S_z spin-symmetry is absent, which opens a possibility of single-particle inelastic electron backscattering. We show that although time-reversal invariance is preserved, inelastic backscattering gives rise to a temperature-dependent deviation from the quantized conductance, $\delta G \propto T^4$. In addition, δG is sensitive to the position of the Fermi level in the gap of the insulator. We present an effective model for this type of helical liquid and determine its parameters explicitly from numerical solutions of microscopic models for two-dimensional topological insulators in the presence of Rashba spin-orbit coupling.

12:15PM Q31.00004 Gate controlled Rotating Spin Wave and chiral FFLO Superconducting phases in Quantum Spin Hall edge ,

QINGLEI MENG, TAYLOR HUGHES, MATTHEW GILBERT, SMITHA VISHVESHVARA, UIUC — We explore the phases exhibited by an interacting quantum spin Hall edge state in the presence of finite chemical potential (applied gate voltage) and spin imbalance (applied magnetic field). We find that the helical nature of the edge state gives rise to orders that are expected to be absent in non-chiral one-dimensional electronic systems. For repulsive interactions, the ordered state has an oscillatory spin texture whose ordering wavevector is controlled by the chemical potential. We analyze the manner in which a magnetic impurity provides signatures of such oscillations. For attractive interactions, finite spin-imbalance, which acts to set up a finite current in unordered QSH edges, results in superconducting order that is characterized by FFLO-type oscillations.

12:27PM Q31.00005 Phonon induced backscattering in helical edge states ,

JAN CARL BUDICH, Institute for Theoretical Physics and Astrophysics, University of Würzburg, FABRIZIO DOLCINI, Dipartimento di Fisica del Politecnico di Torino, Torino Italy, PATRIK RECHER, BJOERN TRAUZETTEL, Institute for Theoretical Physics and Astrophysics, University of Würzburg, MESOSCOPIC PHYSICS GROUP TEAM — A single pair of helical edge states as realized at the boundary of a quantum spin Hall insulator is known to be robust against elastic single particle backscattering as long as time reversal symmetry is preserved. However, there is no symmetry preventing inelastic backscattering as brought about by phonons in the presence of Rashba spin orbit coupling. In this work, we show that the quantized conductivity of a single channel of helical Dirac electrons is protected even against this inelastic mechanism to leading order. We further demonstrate that this result remains valid even when Coulomb interaction is included in the framework of a helical Tomonaga Luttinger liquid.

12:39PM Q31.00006 Optically engineering the topological properties of helical edge states ,

JÉRÔME CAYSSOL¹, Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany, BALÁZS DÓRA, FERENC SIMON, Department of Physics, Budapest University of Technology and Economics, Budafoki út 8, 1111 Budapest, Hungary, RODERICH MOESSNER, Max-Planck-Institut für Physik komplexer Systeme, Nöthnitzer Str. 38, 01187 Dresden, Germany — Time-periodic perturbations can be used to engineer topological properties of matter by altering the Floquet band structure. This is demonstrated for the helical edge state of a spin Hall insulator in the presence of monochromatic circularly polarized light. We first demonstrate that the inherent spin structure of the edge state is influenced by the Zeeman coupling and not by the orbital effect. The photocurrent (and the magnetization along the edge) develops a finite, helicity dependent expectation value and turns from dissipationless to dissipative with increasing radiation frequency, signalling a change in the topological properties. The connection with Thouless' charge pumping and non-equilibrium Zitterbewegung is discussed, together with possible experiments. B. Dora, J. Cayssol, F. Simon, and R. Moessner, Optically engineering the topological properties of a spin Hall insulator, arXiv:1105.5963

12:51PM Q31.00007 ABSTRACT WITHDRAWN —

1:03PM Q31.00008 Fingerprints of a bidimensional topological insulator in Bismuth nanocontacts ,

JUAN JOSE PALACIOS, Universidad Autonoma de Madrid, DANIEL GOSALBEZ, CARLOS SABATER, Universidad de Alicante, JOAQUIN FERNANDEZ-ROSSIER, International Iberian Nanotechnology Laboratory, CARLOS UNTIEDT, Universidad de Alicante — We report on experimental and theoretical work of the electronic transport in Bismuth nanocontacts as created by repeated breaking and indentation using scanning tunneling microscopy techniques. The conductance exhibits a number of unusual features, not shared by normal metals, one of the most striking ones being the presence of plateaus at fractional values of the quantum of conductance at low temperatures. We understand this phenomenon on the basis of the formation of a bilayer of Bismuth (a predicted bidimensional topological insulator) which supports a maximum of a quantum of conductance as expected for its odd number of gapless edge modes. Theoretical transport results based on an atomistic tight-binding model with disorder and spin-orbit coupling permit us to associate the fractional-valued plateaus to the final stages of the breaking of the bilayer.

1:15PM Q31.00009 Spin Josephson effect at the quantum spin Hall edge ,

VASUDHA SHIVAMOGGI, QINGLEI MING, TAYLOR HUGHES, Department of Physics, University of Illinois, MATTHEW GILBERT, Department of Electrical and Computer Engineering, University of Illinois, SMITHA VISHVESHVARA, Department of Physics, University of Illinois — We study a spin Josephson effect in a ferromagnetic junction at the quantum spin Hall (QSH) edge. The helical nature of the QSH edge states has striking consequences for the transport properties of such a junction. We derive an expression for the spin current through the junction as a function of the change in magnetization, similar to the current-phase relation of a Josephson junction. We discuss the novel transport properties of the junction that result from fractionally charged excitations hosted by the QSH edge.

1:27PM Q31.00010 Equality of certain bulk wave functions and edge correlations in $d = 2$ and $d = 3^1$, RAMAMURTI SHANKAR, Yale University, ASHVIN VISHWANATH, University of Californian Berkeley — Ground state wavefunctions and gapless edge physics provide two complementary approaches to the study of quantum Hall liquids. Seminal work of Read and Moore establishes a connection between wavefunctions and 1+1 D Conformal Field Theories, which also describe edge states. Here we provide a transparent derivation of the edge correlation-wavefunction *equality* for certain topological superconductors - theories with edge states, where charge is not conserved. By studying the 2+1 D $p + ip$ superconductor in some detail, we show that the only necessary ingredient is an approximate Lorentz invariance. We are therefore able to extend the derivation to other dimensions, for example an analogous equality of bulk wavefunctions and edge correlations is derived for superfluid $^3\text{He} - B$ in $d = 3$. A key realization is that ground state wavefunctions can be extracted by considering Euclidean partition functions with a time dependent chemical potential. We also demonstrate that the method works for interacting phases, by studying a “fractional” topological superconductor using the parton construction. This connection may help identify novel topological phases in various dimensions.

¹We are grateful for NSF for grants DMR- 0645691 (AV), and DMR-0103639 (RS). RS is grateful to the Department of Physics at UC Berkeley for hosting his sabbatical in Spring 2011, which made this work possible.

1:39PM Q31.00011 Transport on the Surface of Weak Topological Insulators, ROGER MONG, JENS H. BARDARSON, JOEL E. MOORE, University of California, Berkeley — Weak topological insulators have an even number of Dirac cones in their surface spectrum and are thought to be unstable to disorder, which leads to an insulating surface. Here we argue that the presence of disorder alone will not localize the surface states, rather, the presence of a time-reversal symmetric mass term is required for localization. Through numerical simulations, we show that in the absence of the mass term the surface always flow to a stable metallic phase and the conductivity obeys a one-parameter scaling relation, just as in the case of a strong topological insulator surface. With the inclusion of the mass, the transport properties of the surface of a weak topological insulator follow a two-parameter scaling form.

1:51PM Q31.00012 Coherent transport of topological insulator surface states, PIERRE ADROGUER, DAVID CARPENTIER, EDMOND ORIGNAC, Laboratoire de physique, Ecole Normale Supérieure de Lyon, France, JEROME CAYSSOL, LOMA, University Bordeaux-1, France — Topological insulators (TIs) are a new state of matter recently predicted theoretically^{1,2} and realized experimentally. In 3D they are characterized by the presence of gapless surface states which exhibit a linear dispersion, typical of Dirac fermions. Moreover, contrary to conventional materials, these Dirac cones occur in an odd number of Dirac fermions at the surface: ARPES experiments^{3,4} have found a single Dirac cone at the surface of Bi₂Se₃, Bi₂Te₃. This work focuses on the electronic transport properties calculations in the diffusive limit of a single Dirac cone. Specificities of the TI surface states, like the hexagonal warping coupling are taken into account.

2:03PM Q31.00013 Spin polarized multi-terminal transport in helical edge states, SUMATHI RAO, Harish-chandra Research Institute, SOURIN DAS, Delhi University — We propose a three-terminal spin polarized scanning tunneling microscope setup for probing the helical nature of the edge states that appear in the quantum spin Hall system. We show that the three-terminal tunneling conductance depends on the magnetic anisotropy, i.e., the angle between the magnetization of the tip and the local orientation of the electron spin on the edge. We show that chiral injection of an electron into the helical Luttinger liquid is associated with fractionalization of the spin and charge of the injected electron. Finally, we show that the magnetic anisotropy of the probe also leads to Fabry-Perot like two-terminal resonances in charge transport.

Wednesday, February 29, 2012 11:15AM - 2:15PM –
Session Q32 DMP DCOMP: Focus Session: Dielectric, Ferroelectric, and Piezoelectric Oxides - Multiferroics and Magnetoelectrics 261

11:15AM Q32.00001 Skyrmions in Multiferroics, SHINICHIRO SEKI, Department of Applied Physics, University of Tokyo, XIUZHEN YU, RIKEN CMRG/CERG, SHINTARO ISHIWATA, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo — Magnetic skyrmion is a topologically stable particle-like object, which appears as nanometer-scale vortex-like spin texture in a chiral-lattice magnet. In metallic materials, electrons moving through skyrmion spin texture gain a nontrivial quantum Berry phase, which provides topological force to the underlying spin texture and enables the current-induced manipulation of magnetic skyrmion. Such electric controllability, in addition to the particle-like nature, is a promising advantage for potential spintronic device applications. In this talk, we report the experimental discovery of magnetoelectric skyrmion in an insulating chiral-lattice magnet Cu₂OSeO₃. We find that the skyrmion can magnetically induce electric polarization through the relativistic spin-orbit interaction, which implies possible manipulation of the skyrmion by external electric field without loss of joule heating. The present finding of multiferroic skyrmion may pave a new route toward the engineering of novel magnetoelectric devices with high energy efficiency.

11:27AM Q32.00002 Dynamical matrix in magnetoelectrics¹, RAFFAELE RESTA, Physics Dept., Univ. of Trieste — In ordinary dielectrics the dynamical matrix at the zone center is a nonanalytic function of degree zero in the wavevector $\mathbf{q}$. Its expression (for a crystal of arbitrary symmetry) is well known and is routinely implemented in first principle calculations. The nonanalytic behavior occurs in polar crystals and owes to the coupling of the macroscopic electric field $\mathbf{E}$ to the lattice. In magnetoelectric crystals both electric and magnetic fields, $\mathbf{E}$ and $\mathbf{H}$, are coupled to the lattice, formally on equal footing. I provide the general expression for the zone center dynamical matrix in a magnetoelectric, where the $\mathbf{E}$ and $\mathbf{H}$ couplings are accounted for in a symmetric way. As in the ordinary case, the dynamical matrix is a nonanalytic function of degree zero in $\mathbf{q}$, and is exact in the harmonic approximation. Besides the above major result, I will also discuss other related issues: (i) The Lyddane-Sachs-Teller relationship for MEs, where the fields $\mathbf{E}$ and $\mathbf{H}$ are (once more) dealt with in a symmetric way; (ii) The microscopic origin of the coupling of magnetic fields to the lattice, which may look counterintuitive; (iii) The relationship to first-principle implementations, where in the simplest cases $\mathbf{E}$ and $\mathbf{B}$ (not $\mathbf{H}$) are zero.

11:39AM Q32.00003 Multiferroic behavior in $\text{Lu}_2\text{MnCoO}_6$, VIVIEN ZAPF, E.-D. MUN, B.G. UELAND, J.D. THOMPSON, J. SINGLETON, Los Alamos National Laboratory, Los Alamos, NM, J. GARDNER, NIST Center for Neutron Research National Institute of Standards and Technology, Gaithersburg, MD, S. YÁÑEZ-VILAR, M. SÁNCHEZ-ANDÚJAR, M.A. SEÑARIS-RODRIGUEZ, Dpto. Química Fundamental, U. Coruna, Coruna (Spain), J. MIRA, Dpto. Física Aplicada, U. Santiago de Compostela, Santiago de Compostela (Spain), N. BISKUP, Dpto. Tecnologías de la Información, Inst. de Ciencia de Materiales, Madrid (Spain), C.D. BATISTA, Los Alamos National Laboratory, Los Alamos, NM — $\text{Lu}_2\text{MnCoO}_6$ is a new member of the multiferroics with coupling between net magnetization and net electric polarization. Similar to $\text{Ca}_3\text{MnCoO}_6$, an up-up-down-down order of the magnetic spins is found that breaks spatial-inversion symmetry and creates an electric polarization. Unlike $\text{Ca}_3\text{MnCoO}_6$, the Co and Mn ions are both in a $S = 3/2$ state, the ordering temperature is 42 K, and the magnetic field needed to suppress electric polarization is 2 T. We present an experimental study of the multiferroic properties and spin structure including neutron diffraction, electric polarization, magnetization, dielectric constant, and specific heat measurements.

11:51AM Q32.00004 Structural and Magnetic Properties of $\text{Ln}_2\text{CoMnO}_6$ ($\text{Ln} = \text{Dy}$ and La) Produced by Combustion Synthesis¹, PEDRO LINHARES C. FILHO, UFPE, PETRUCIO BARROZO, UFS, N.R. DILLEY, Quantum Design, J. ALBINO AGUIAR, UFPE, UFPE TEAM, UFS COLLABORATION, QUANTUM DESIGN COLLABORATION — The lanthanum manganites have been intensively studied in recent years. These compounds present a wide variety of properties of great technological and scientific interest. The half-doped lanthanum manganite with Co in Mn site have ferroelectric and ferromagnetic properties with critical temperatures close to room temperature. The mechanisms responsible for magnetoelectric coupling in these materials are not yet understood. In this work we study the effect of Dy doping at La site in the structural and magnetic properties of lanthanum manganite half-doped with Co obtained by combustion method. The dark powder obtained was heat-treated in air and cooled slowly in the oven. The samples were characterized structurally by X-ray diffractometry with Rietveld refinement analysis. Magnetization measurements as a function of temperature and the magnetic field were carried out on the SQUID magnetometer in temperature interval of 5 - 300 K and in magnetic fields up to 7T. The results show an decreases of the magnetic transition temperature when we substitute the La by Dy.

¹Work financed by CAPES, CNPq and FACEPE (Grant 0589-1.05/08).

12:03PM Q32.00005 Emergence of a new order reconciling ferroelectric and antiferrodistortive instabilities in EuTiO_3 , JONG-WOO KIM, PHILIP RYAN, Argonne National Laboratory, PAUL THOMPSON, SIMON BROWN, XMaS, European Synchrotron Radiation Facility, France, PETER NORMILE, Universidad de Castilla-la Mancha, Spain, ANKE WEIDENKAFF, University of Bern, Swiss — Control of magnetic moments with electric field or electric polarization with magnetic field can open new possibilities to develop future applications of low power sensors, data storages and spintronics. However, in general this magnetoelectric coupling is extremely small for device application. Although, a substantial change of the dielectric constant under magnetic field was observed in the EuTiO_3 system. This finding offers an insight into how the electric polarization couples with the magnetism through phonon modes to the spin of the Eu atoms. We present recent x-ray diffraction data on a single crystal EuTiO_3 providing the direct proof of antiferrodistortive (AFD) TiO_6 octahedral rotations correlated with the quantum paraelectric state. Forming an incommensurate AFD order mediates the competition between antiferroelectric and AFD order. We discuss the origin of magnetoelectric coupling based on the interplay of AFD order and antiferromagnetic interactions.

12:15PM Q32.00006 Spin-phonon coupling in the rare-earth orthoferrite DyFeO_3 , ANDREW LAFORGE, University of California, Santa Cruz, JEFFREY WHALEN, THEO SIEGRIST, Florida State University, ARTHUR RAMIREZ, ZACK SCHLESINGER, University of California, Santa Cruz — The rare-earth orthoferrite (RFeO_3) canted antiferromagnets are known to exhibit a wide array of magnetic properties, including spin reorientation transitions and compensation points between the rare-earth and iron sublattices. Furthermore, strong magnetoelastic coupling has been observed to lead to field-induced multiferroism with a large dielectric polarization. Here we present an infrared optical study of DyFeO_3 , focusing on the evolution of the phonon structure with temperature. Polarized single-crystal reflectance measurements are supplemented with magnetization and dielectric constant measurements to illuminate the role of spin-phonon coupling in the lattice dynamics.

12:27PM Q32.00007 A first principles investigation of a hexagonal ferrite LuFeO_3 , HENA DAS, Postdoctoral Research Associate, CRAIG J. FENNIE, Assistant Professor — The multiferroic hexagonal manganites RMnO_3 ($\text{R}=\text{Dy-Lu,Y}$), are a fascinating class of materials that display an unusual, complex interplay between structural, polar and magnetic domains. For example, the electric polarization in these compounds are found to be a by-product of a trimerized (zone-boundary) lattice distortion, arising from the ionic size mismatch between R^{+3} and Mn^{+3} ions. As a direct consequence of this improper ferroelectric transition, the ferroelectric and structural trimer domains are locked; rotation of structural distortion at a structural domain not only flips the polarization, but also rotates the spins. The hexagonal ferrites RFeO_3 ($\text{R}=\text{Lu,Er-Tb}$) crystallize in the same polar structure as the manganite counterparts. However, unlike the $\text{M}=0$, non-collinear antiferromagnetism in manganites, the ferrites have recently been shown to display weak ferromagnetic behaviour[1], the underlying microscopic mechanism of which so far is not understood. In the present study, using first principles density functional calculations, we investigate the structural and magnetic properties of LuFeO_3 , one of the members of this ferrite series.

[1] A. R. Akbashev, A. S. Semisalova, N. S. Perov and A. R. Kaul, Appl. Phys. Lett **99**, 122502 (2011).

12:39PM Q32.00008 Atomic Resolution Valence Mapping in LuFe_2O_4 in an Aberration Corrected STEM¹, J.A. MUNDY, Cornell University, C.M. BROOKS, R. MISRA, P. SCHIFFER, Pennsylvania State University, D.A. MULLER, D.G. SCHLOM, Cornell University — LuFe_2O_4 is a multiferroic with the simultaneous existence of ferroelectricity and ferrimagnetism at the highest temperature of any known material. The improper ferroelectricity is attributed to charge ordering in the Fe-O layers, however, a direct measure of the Fe valence on individual columns in the crystal remains elusive. Scanning Transmission Electron Microscopy (STEM) in combination with Electron Energy Loss Spectroscopy (EELS) allows for spatially resolved, chemically sensitive investigation of oxide materials. We used a Nion 5th-order aberration corrected 100 keV dedicated STEM to collect spectroscopic images from a thin film of LuFe_2O_4 on MgAl_2O_4 to map the two-dimensional concentrations of every atomic species in the film. The Fe valence on individual columns was measured, however, no statistically significant modulation—as would be consistent with charge ordering—was observed. Finally, changes in the fine structure in the EELS O atoms in the Lu-O and Fe-O planes, was mapped in two-dimensions.

12:51PM Q32.00009 Anisotropy in the magnetic and multiferroic properties of $\text{LuFe}_2\text{O}_{4-\delta}$ single crystals with varying oxygen stoichiometry, G. BALAKRISHNAN, R.A. MCKINNON, M.R. LEES, Department of Physics, University of Warwick, Coventry CV4 7AL, UK — LuFe_2O_4 is a multiferroic, where the origin of the ferroelectricity is attributed to electron correlations and directly linked to the charge ordering of Fe^{2+} and Fe^{3+} in the lattice. The multiferroic properties of this system are known to be sensitive to the oxygen stoichiometry. Large single crystals of $\text{LuFe}_2\text{O}_{4-\delta}$ with varying oxygen stoichiometry have been produced by the floating zone technique. Detailed magnetic susceptibility, dielectric constant and polarization measurements have been carried out along specific crystallographic axes of the single crystals over a wide temperature range to study the anisotropic properties. The effect of altering the $\text{Fe}^{2+}/\text{Fe}^{3+}$ stoichiometry on the physical properties of $\text{LuFe}_2\text{O}_{4-d}$ is discussed.

1:03PM Q32.00010 Charge dynamics in a frustrated charge ordered multiferroic system, MAKOTO NAKA, SUMIO ISHIHARA, Department of Physics, Tohoku University — Electronic ferroelectricity is known as phenomena where the electric polarization is caused by the electronic charge order without inversion symmetry. This is seen in some transition metal oxides, e.g. LuFe_2O_4 , and organic salts. It is suggested from the theoretical work [1] that large charge fluctuation and frustration are responsible for the electric polarization. This charge fluctuation is expected to govern dynamical properties. Actually, the measurements of the low frequency dielectric dispersion and the optical conductivity indicate that the large charge fluctuation remains in charge ordered phase in LuFe_2O_4 . Motivated by these experimental results, we study charge dynamics in charge ordered system on the layered triangular lattice. We adopt the V-t model where the inter-site electron transfers and the inter-site Coulomb interactions are taken into account. We analyze this model by utilizing the exact diagonalization method and focus on effects of frustration in the charge dynamics. In the 3-fold charge ordered phase associated with the electric polarization, the optical conductivity shows multiple-peak structure in a wide energy range. In finite temperature, the low frequency oscillator strength of the optical conductivity and the dynamical charge correlation functions in 3-fold charge ordered phase decrease slower than those in the non-polar 2-fold charge ordered phase. These results imply the strong charge fluctuation in the 3-fold charge ordered phase due to the geometrical frustration. [1] M. Naka et al. Phys. Rev. B. **77** 224441.

1:15PM Q32.00011 Multiferroic M-type hexaferrites with room-temperature conical spin structure, Y. TAGUCHI, Y. TOKUNAGA, CMRG and CERG, RIKEN ASI, Japan, Y. KANEKO, ERATO MF, JST, Japan, D. OKUYAMA, CMRG and CERG, RIKEN ASI, Japan, S. ISHIWATA, Dept. of Appl. Phys., Univ. of Tokyo, Japan, T. ARIMA, Dept. of Adv. Mat. Sci., Univ. of Tokyo, Japan, S. WAKIMOTO, K. KAKURAI, Japan Atomic Energy Agency, Japan, Y. TOKURA, CMRG and CERG, RIKEN ASI, ERATO MF, JST, Univ. of Tokyo, Japan — Magnetic and magnetoelectric properties have been investigated for single crystals of Sc-doped M-type hexaferrites [1]. Magnetization and neutron diffraction studies have indicated that a longitudinal conical state is stabilized up to room temperature by tuning the Sc concentration. Magnetoelectric measurements have shown that electric polarization can be induced by applying a transverse magnetic field at lower temperatures, and that the spin helicity is nonvolatile and endurable up to near the transition temperature from conical to collinear state. In addition, the behavior of the polarization vector upon the reversal of magnetization varies with temperature, thereby allowing us to control the relation between spin helicity and magnetization vectors with magnetic field and temperature. This work was in part supported by FIRST program on "Quantum Science on Strong Correlation" from JSPS. [1] Y. Tokunaga, Y. Kaneko, D. Okuyama, S. Ishiwata, T. Arima, S. Wakimoto, K. Kakurai, Y. Taguchi, and Y. Tokura, Phys. Rev. Lett. **105**, 257201 (2010)

1:27PM Q32.00012 The magnetoelectric effect in the $\text{RAl}_3(\text{BO}_3)_4$ ($\text{R}=\text{Tb, Ho, Er, and Tm}$), K.-C. LIANG, R. P. CHAUDHURY, B. LORENZ, TCSUH and Department of Physics, University of Houston, Houston, TX 77204, USA, L.N. BEZMATERNYKH, V.L. TEMEROV, Institute of Physics, Siberian Division, Russian Academy of Sciences, Krasnoyarsk, 660036, Russia, C.W. CHU, TCSUH and Department of Physics, University of Houston, Houston, TX 77204, USA — We study the magnetoelectric (ME) effect of the rare earth aluminum borates, $\text{RAl}_3(\text{BO}_3)_4$ ($\text{R}=\text{Tb, Ho, Er, and Tm}$). The magnetic, magnetoelectric, and magnetostrictive properties were investigated between 2K and 300K with different orientation of fields up to 70kOe. A giant magnetoelectric polarization, $3600 \mu\text{C}/\text{m}^2$, is found in $\text{HoAl}_3(\text{BO}_3)_4$ while a 70kOe transverse magnetic geometry field is applied. This value is significantly larger than that previously reported in all other bulk crystalline linear magnetoelectric or multiferroic materials. Furthermore, the ME polarization decreases with increasing magnetic anisotropy of the rare earth moment. The magnetostrictive measurements show that there is a strong coupling between the 4-f moments and the lattice. Our data further imply that the field-induced ionic displacements in a unit cell give rise to a change of structural symmetry from non-polar to polar symmetry.

1:39PM Q32.00013 Polar Nanodomains and Giant Converse Magnetoelectric Effect in Charge-Ordered Fe_2OBO_3 , HUAIXIN YANG, HUANFANG TIAN, YUANJUN SONG, YUANBIN QIN, Institute of Physics, Chinese Academy of Sciences, YONGGANG ZHAO, Department of Physics, Tsinghua University, CHAO MA, JIANQI LI, Institute of Physics, Chinese Academy of Sciences — Charge ordering (CO) is considered to be an important issue that leads to metal-insulator transitions in numerous materials and also shows possible correlations to many notable physical phenomena, such as colossal magnetoresistance, superconductivity and multiferroics. In recent investigations, oxyborate Fe_2OBO_3 has been found to show certain structural and physical features in connection with a continuous CO transition [1, 2]. By using *In-situ* TEM technique, we revealed that the charge-ordering transition characterized by an incommensurate modulation could evidently result in remarkable polar nanodomains at low temperatures. This kind of nanodomain could play a critical role in triggering a high dielectric constant and notable dielectric dispersion as observed in Fe_2OBO_3 . Moreover, measurements of the magnetoelectric coupling under electrical field demonstrate the existence of giant electrically induced changes in magnetization around the magnetic transition [1, 2]. 1.Y. J. Song et al., Phys. Rev. B **81**, 020101(R) (2010). 2.H. X. Yang et al., Phys. Rev. Lett. **106**, (2011) 016406.

1:51PM Q32.00014 Ferroelectric Phase Transition in $\text{Pb}_5\text{Cr}_3\text{F}_{19}$ and Coupling of Electric Polarization and Magnetization, ZVONKO TRONTELJ, Physics Department, IMFM, Ljubljana, DAMIR PAJIC, Department of Physics, University of Zagreb, Croatia, MARKO JAGODIC, Physics Department, IMFM, Ljubljana, PAVEL CEVC, Josef Stefan Institute, Ljubljana, Slovenia — The ferroelectric fluoride $\text{Pb}_5\text{Cr}_3\text{F}_{19}$ with ferroelectric/paraelectric phase transition at 545 K offers a possibility of multiferroic behavior. The paramagnetic Cr^{3+} ion with electronic spin 3/2 has two inequivalent positions in the unit cell and is responsible for magnetic properties. These properties were measured with a SQUID magnetometer from 2 K to 630 K in addition to our earlier EPR measurements. At the ferroelectric/paraelectric phase transition the lattice parameters (c and a unit cell dimensions) experience relatively big changes leading to alteration of magnetic dipole-dipole and exchange interactions. The temperature dependence of magnetic susceptibility times temperature around the phase transition was analyzed following the usual free energy expansion. We obtained that a coupling between the electric polarization and the magnetization is quadratic. A magnetic anomaly was observed below 25 K.

2:03PM Q32.00015 The origin and coupling mechanism of magnetoelectric effect in $\text{TMCl}_2\cdot 4\text{SC}(\text{NH}_2)_2$ ($\text{TM} = \text{Ni and Co}$), E. MUN, National High Magnetic Field Laboratory (NHMFL), Los Alamos National Lab (LANL), Los Alamos, NM, J. WILCOX, J. MANSON, Department of Chemistry and Biochemistry Eastern Washington University Cheney, WA 99004 USA, B. SCOTT, MPA-MC, LANL, Los Alamos, NM, P. TOBASH, E. BAUER, MPA-CMMS, LANL, Los Alamos, NM, P. SENGUPTA, Nanyang Technological Institute, Singapore, C. BATISTA, Theory division, LANL, Los Alamos, NM, V. ZAPF, National High Magnetic Field Laboratory (NHMFL), Los Alamos National Lab (LANL), Los Alamos, NM — Most research on multiferroics and magnetoelectric effects to date has focused on inorganic oxides. Metal organic frameworks (MOF) are a new field in which to search for ferroelectricity and explore new coupling mechanisms between electricity and magnetism. We will present the magnetic and electric properties of $\text{NiCl}_2\cdot 4\text{SC}(\text{NH}_2)_2$, DTN, and $\text{CoCl}_2\cdot 4\text{SC}(\text{NH}_2)_2$, DTC, compounds as a function of temperature, magnetic, and electric field. We gain insights into the coupling mechanism by observing that in DTN the electric polarization closely tracks the magnetic ordering whereas in DTC it does not. For DTN, all electrically polar thiourea, $\text{SC}(\text{NH}_2)_2$, molecules are tilted in the same direction along the c-axis, breaking spatial inversion symmetry, whereas for DTC, two thiourea molecules are pointing up and the other two thiourea molecules are pointing down direction with respect to c-axis, perfectly canceling the net electrical polarization. Thus the magnetoelectric coupling mechanism is likely magnetostrictive adjustments of the thiourea molecule orientation in response to magnetic order.

Session Q33 GIMS: Focus Session: X-ray and Neutron Instruments and Measurement Science

11:15AM Q33.00001 Science Enabled by the Advanced Photon Source Upgrade¹, G. BRIAN STEPHENSON, Argonne National Laboratory — The Advanced Photon Source (APS) at Argonne National Laboratory is embarking on a major Upgrade that will significantly enhance capabilities for research using high brilliance, high energy synchrotron x-ray beams. The APS is a DOE Office of Science user facility that provides access to x-ray scattering, spectroscopy, and imaging instruments through an open, peer-reviewed proposal process. Currently 64 simultaneously operating beamlines are used by more than 4000 researchers each year across the full range of science and technology fields. The APS Upgrade project will provide major improvements to the x-ray sources as well as more than a dozen new or upgraded beamlines. Key areas of emphasis are using penetrating, high energy x-rays for atomic-scale studies of real materials in real time under real conditions, imaging of hierarchical structures on length scales from millimeters to nanometers, and ultrafast studies of chemical and physical processes on time scales down to picoseconds. I will illustrate the science enabled by the APS Upgrade using examples such as developing synthesis of new materials with outstanding properties and probing picosecond dynamics in energy conversion systems.

¹Work supported by the Dept. of Energy, Office of Basic Energy Sciences under contract DE-AC02-06CH11357.

11:51AM Q33.00002 Initial Results and Future Plans for the Soft X-ray Instrument for Materials at the Linac Coherent Light Source (LCLS), WILLIAM SCHLOTTER, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, CA, OLEG KRUPIN, European XFEL, Hamburg, Germany, MICHAEL MINITTI, JOSHUA TURNER, Linac Coherent Light Source, SLAC National Accelerator Laboratory, Menlo Park, CA — For two years ultrafast high intensity x-ray pulses have been available at the Linac Coherent Light Source, the x-ray free electron laser at the SLAC National Accelerator Laboratory. The soft x-ray instrument (SXR) operates at an energy range from 480eV-2000eV and features a plane grating monochromator as well as a bendable refocusing mirror system. The measured performance of the instrument will be presented as well as the future direction for instrumentation development.

Acknowledgement: This research was carried out on the SXR Instrument at the Linac Coherent Light Source (LCLS), a division of SLAC National Accelerator Laboratory and an Office of Science user facility operated by Stanford University for the U.S. Department of Energy. The SXR Instrument is funded by a consortium whose membership includes the LCLS, Stanford University through the Stanford Institute for Materials Energy Sciences (SIMES), Lawrence Berkeley National Laboratory (LBNL), University of Hamburg through the BMBF priority program FSP 301, and the Center for Free Electron Laser Science (CFEL).

12:03PM Q33.00003 Microfocusing options for sector 3 of the Advanced Photon Source upgrade project¹, A.M. ALSMADI, Umm Al-Qura University, A. ALATAS, J. ZHAO, L. YAN, L. GAO, E.E. ALP, Argonne National Laboratory — Synchrotron radiation from third generation, high-brilliance rings is an ideal source for x-ray microbeams. The aim of this report is to describe a microfocusing scheme that combines both a toroidal mirror and a Kirkpatrick-Baez (KB) mirrors for upgrading the existing optical system for inelastic x-ray scattering experiments at sector 3 at the Advanced photon Source (APS). Shadow ray tracing simulations show that this combination can provide beam sizes of $4.5 \mu\text{m}$ (H) $\times$ $0.6 \mu\text{m}$ (V) (FWHM) at the end of the existing D-station (66 m from the source) with a transmission of up to 59 % and a beam size of $3.7 \mu\text{m}$ (H) $\times$ $0.46 \mu\text{m}$ (V) (FWHM) at the front end of proposed E-station (68 m from the source) with a transmission of up to 57 %. With this new setup, experiments that combine high pressure, low temperature and external magnetic field can be done.

¹We would like to thank the IAEA for providing Dr. A. M. Alsmadi with a supported fellowship to stay at the APS for 6 months during this project.

12:15PM Q33.00004 Advances in X-ray Raman spectroscopy at Stanford Synchrotron Radiation Lightsource, DIMOSTHENIS SOKARAS, DENNIS NORDLUND, TSU-CHIEN WENG, ROBERTO ALONSO MORI, UWE BERGMANN, SLAC National Accelerator Laboratory — We present a state-of-the-art x-ray Raman spectroscopy end-station recently developed, installed, and operated at the Stanford Synchrotron Radiation Lightsource. The end-station consists of two multichannel Johann type spectrometers arranged on a Rowland circle of 1m. The first one, positioned at the forward scattering angles (low-q), consists of 40 diced and spherically bended Si(110) crystals of 4" of diameter providing a large solid angle of detection as well as an overall energy resolution of about 270 meV at 6462.20 eV. The second spectrometer, consisting of 14 spherically bent Si(110) crystal analyzers, is positioned at the backward scattering angles (high-q) enabling the study of non-dipole transitions. These features, in particular the improved total resolution with a substantial increase in solid angle, positions the instrumentation as a unique alternative to soft x-ray absorption for difficult sample conditions and bulk sensitive measurements, which allows a systematic implementation of this photon-in/photon-out hard x-ray technique on emerging research of multidisciplinary scientific fields in energy-related science, physics, and material science. Preliminary results and prospects will be presented and discussed, in particular for applications in Energy Science.

12:27PM Q33.00005 Facility Overview and Double-Focusing Thermal Triple-Axis Spectrometer at the NCNR, JEFFREY LYNN, National Institute of Standards and Technology — We will briefly overview the neutron scattering instrumentation at the NCNR, but will focus the talk on the capabilities of the new thermal triple-axis spectrometer is located at the BT-7 beam port [1]. This spectrometer takes full advantage of the large 165 mm diameter reactor beam to tailor the dual $20 \times 20 \text{ cm}^2$ double-focusing monochromator system to provide monochromatic fluxes exceeding $10^8 \text{ n/cm}^2/\text{s}$ onto the sample. The two monochromators installed are PG(002) and Cu(220), which provide incident energies for 5 meV to above 500 meV. The computer controlled analyzer system offers six standard modes of operation, including a diffraction detector, a position-sensitive detector (PSD) in diffraction mode, horizontal energy focusing analyzer with detector, a Q-E mode employing a flat analyzer and PSD, a constant-E mode with the analyzer crystal system and PSD, and a conventional mode with a selection of Söller collimators and detector. Additional configurations for specific measurement needs are also available. The capabilities and performance will be discussed and examples of published data presented.

1:03PM Q33.00006 ABSTRACT WITHDRAWN —

1:15PM Q33.00007 Advanced Thermal Neutron Detectors, GRAHAM SMITH, JACK FRIED, GIANLUIGI DE GERONIMO, GEORGE MAHLER, DON MAKOWIECKI, JOE MEAD, VELJKO RADEKA, NEIL SCHAKNOWSKI, EMERSON VERNON, BO YU, Brookhaven National Laboratory — With the advent of new high intensity spallation sources, there is a vital need for development of advanced position sensitive detectors. Using neutron conversion in helium 3, which yields a large signal with excellent background rejection capability, our research program focuses on improving the rate capability, resolution, efficiency and long term stability of detectors for neutron scattering studies. We have developed a suite of detectors using proportional chambers, the latest being an array of curved, multi-wire segments with interpolating cathode strip electrodes operating simultaneously and seamlessly in a single gas volume. With rate capability of nearly 1 million per sec, this instrument has significantly advanced the state-of-the-art for protein crystallography. To attain even higher count rates, a new concept based on operation in the ionization mode is being explored, in which direct ionization from a neutron conversion is collected with unity gain on one of many pads that form the anode plane. Each pad is implemented with charge sensitive electronics, using purpose-designed application specific integrated circuits. A prototype device with 48 by 48 pads has been successfully developed. Examples of measurements at major neutron user facilities will be presented.

1:27PM Q33.00008 ABSTRACT WITHDRAWN —

1:39PM Q33.00009 The wetting behavior of electrolytes at charged carbon electrode materials probed using neutron scattering¹, JOSE LEO BAÑUELOS, PASQUALE FULVIO, GERNOT ROTHER, LAWRENCE ANOVITZ, JIM BROWNING, Oak Ridge National Laboratory — Breakthroughs in the performance of energy storage technologies come from efficient combinations of novel electrolytes and electrode materials. Knowledge of the structure of these materials under applied electric fields is necessary to better tailor them to our energy needs. Neutron scattering, as a structural probe to investigate the ordering of electrolytes at an interface, or the effects of confinement on an electrolyte in a nanoporous matrix, is well suited since the electrolytes commonly used contain hydrogen and the host matrix can often contain active sites that are difficult to discern without the use of contrast matching via isotopic substitution. We present small angle neutron scattering results, conducted at the EQ-SANS (ORNL) instrument and at the Low-Q Diffractometer (LANL), from in situ electrochemical measurements of a deuterated ionic liquid, and of aqueous electrolytes, in a mesoporous carbon membrane at different applied potentials over time. Recent neutron reflectometry measurements (LR, SNS) complement the observed behavior from SANS. We observe a higher electrolyte density near the electrode material surface, compared to without an applied potential. Furthermore, this high density region persists long after the applied potential is removed.

¹This work supported by the U.S. DOE, BES, as part of an Energy Frontier Research Center. Neutron scattering was conducted at the Lujan Neutron Scattering Center and Spallation Neutron Source, sponsored by the Div. of Sci. User Facilities, U.S. DOE.

1:51PM Q33.00010 Combined X-Ray and Neutron Powder Diffraction Studies of Nanoscale $\text{Ca}_{5-x}\text{Fe}_x(\text{PO}_4)_3\text{OH}$ Systems, A. KYRIACOU, TH. LEVENTOURI, Florida Atlantic University, B.C. CHAKOUMAKOS, V.O. GARLEA, C.D. CRUZ, Neutron Scattering Science Division, Oak Ridge National Laboratory, A.J. RONDINONE, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, K.D. SORGE, Florida Atlantic University — Multi-substituted hydroxyapatite (HAp) with crystallite size 4-130 nm is the major mineral phase in physiological apatites. Substitutions at all ionic sites affect their physicochemical properties. Fe is one of the minor substitutions at the Ca sites of HAp. It is important because it reduces the solubility of HAp, functioning as a cavities preventive agent, whereas Fe overload leads to a decreased mechanical strength and osteoporosis. Powder x-ray and neutron diffraction methods as well as energy-filtered transmission electron microscopy were used to study the effect of Fe substitution on the crystal structure properties of the $\text{Ca}_{(5-x)}\text{Fe}_x(\text{PO}_4)_3\text{OH}$ systems. Single phase HAp is identified in systems with $x \leq 0.1$. Hematite is formed for higher x . Simultaneous Rietveld refinement of the x-ray and neutron diffraction patterns reveals an unexpected increase of the a-lattice constant. It is attributed to the increase of the Ca1-O3 and Ca2-O1 interatomic distances indicating a local lattice relaxation. Fe substitutes in both Ca1 and Ca2 sites with a preference to the Ca2 site and an occupancy up to 0.05 for $x=0.3$. Magnetic measurements reveal a transition from the diamagnetic state of the HAp to the paramagnetic of the Fe-doped systems.

2:03PM Q33.00011 Profile retrieval using Spin-Echo Resolved Grazing Incidence Scattering combined with dynamical scattering theory¹, RANA ASHKAR, Physics Department, Indiana University Bloomington, ROGER PYNNE, Physics Department, Indiana University Bloomington and Neutron Science Directorate, Oak Ridge National Laboratory — Spin-echo Resolved Grazing Incidence Scattering (SERGIS) is a novel neutron scattering technique that provides lateral and in-depth characterization of density correlations in thin films and at interfaces. The method can be used to study the self-assembly of materials in a periodic array of nano-channels such as a diffraction grating. Since scattering from such periodic structures is dominated by dynamical effects that are not accounted for in approximate scattering theories, we developed a dynamical theory (DT) model, based on a Parratt formalism, and tested it on SERGIS data collected from a set of nanostructured gratings with different profiles in various scattering geometries. The model shows good agreement with all the data sets obtained so far. We found that the SERGIS technique is very sensitive to slight variations in the scattering geometry and the sample profile and the DT calculations accurately reproduce this sensitivity. This is a very promising step in combining a neutron scattering technique with an exact theory to retrieve profile information of periodic samples with unknown structures and to probe the morphology of self-assemblies in periodic nano-confinements.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q34 DCP: Focus Session: Nano IV: Nanocatalysis 107A

11:15AM Q34.00001 Cluster size effects on chemical and physical properties of model catalysts, SCOTT ANDERSON, University of Utah — Model catalysts are prepared by deposition of size- and energy-selected metal clusters on well characterized solid supports in an ultrahigh vacuum system. The system provides capabilities to probe the physical properties of the samples by X-ray and ultraviolet photoelectron spectroscopy (XPS, UPS), ion neutralization spectroscopy (INS), and low energy ion scattering (ISS). The chemical properties can be probed by a variety of pulsed, temperature-programmed, and constant temperature mass spectrometric methods, and resulting changes in physical properties from interactions with adsorbates are probed by XPS, UPS, INS, and or ISS. Recently, capabilities for in situ electrochemical characterization were added. Results from several systems will be presented, including gas-surface reactions over Pd/alumina and Pd/titania, and solution phase oxygen reduction over Pt/glassy carbon.

11:51AM Q34.00002 CO Oxidation on Copper Oxide Cluster Ions, MASAHIKO ICHIHASHI, Toyota Technological Institute, SHINICHI HIRABAYASHI, Genesis Research Institute, Inc., YOSHIYUKI KAWAZOE, Tohoku University — We investigated the reaction of CO and O_2 on size-selected copper cluster ions, Cu_n^+ ($n=4-18$) and Cu_n^- ($n=4-11$), by use of a tandem mass-spectrometer equipped with octopole ion guides. A coadsorbing product, $\text{Cu}_n\text{O}_2(\text{CO})^+$, was observed in the reaction of Cu_nO_2^+ with CO, and it was found that CO adsorbs onto Cu_nO_2^+ more efficiently than onto Cu_n^+ in $n \geq 9$. This shows the cooperative coadsorption of O_2 and CO. On the other hand, in the reaction of Cu_nO_2^- with CO, a reduced product, Cu_nO^- , was obtained instead of the coadsorbing product, $\text{Cu}_n\text{O}_2(\text{CO})^-$. In particular, Cu_5O_2^- and Cu_9O_2^- have relatively high efficiency for the production of Cu_nO^- . This result suggests the production of CO_2 by the oxidation of CO on Cu_nO_2^- . The DFT calculation indicates that the activation energy in the reaction of $\text{Cu}_5\text{O}_2(\text{CO})^- \rightarrow \text{Cu}_5\text{O}(\text{CO}_2)^-$ is only 0.79 eV while that of the corresponding cation is 1.79 eV. The structure of Cu_n^- is more flexible than that of Cu_n^+ probably because of its excess electron. It is concluded that the stabilization of the transition state and the decrease of the activation energy make the CO oxidation proceed on Cu_nO_2^- .

12:03PM Q34.00003 Effective rate constants for nanostructured heterogeneous catalysts, SHAUN HENDY, NICOLA GASTON, PHILIP ZHANG, Industrial Research Ltd, NAT LUND, Victoria University of Wellington — There is currently a high level of interest in the use of nanostructured materials for catalysis. For instance, gold, which is largely inert in the bulk, can exhibit strong catalytic activity when in nanoparticle form. With precious metal catalysts such as Pt and Pd in high demand, the use of these materials in nanoparticle form can also substantially reduce costs by exposure of more surface area for the same volume of material. When reactants are plentiful, the effective activity of a nanoparticulate catalyst will increase roughly with its surface area. However, under diffusion-limited conditions, the reactant must diffuse to active sites on the catalyst, so a high surface area and a high density of active sites may bring diminishing returns if reactant is consumed faster than it arrives. Here we apply a mathematical homogenisation approach to derive simple expressions for the effective reactivity of a nanostructured catalyst under diffusion limited conditions that relate the intrinsic rate constants of the surfaces presented by the catalyst to an effective rate constant. When highly active catalytic sites, such as step edges or other defects are present, we show that distinct limiting cases emerge depending on the degree of overlap of the reactant depletion zone about each site. In gases, the size of this depletion zone is approximately the mean free path, so the effective reactivity will depend on the structure of the catalyst on that scale. We discuss implications for the optimal design of nanoparticle catalysts.

12:15PM Q34.00004 Towards a Molecular Level Understanding of CO and H₂ Adsorption and Dissociation on Cobalt Nanoparticles, EMILY LEWIS, APRIL JEWELL, GEORGIOS KYRIAKOU, CHARLES SYKES, Tufts University — The development of sustainable energy technologies, including the production of synthetic fuels, is of global importance. Fischer-Tropsch synthesis (FTS) has recently gained increased attention as it involves the formation of hydrocarbons via the catalytic conversion of syngas (CO and H₂), which can be derived from renewable sources. FTS is often performed using Co-based catalysts that are greatly affected by the adsorption state of reactants, as well as nanoparticle shape and size. Here we have used low-temperature scanning tunneling microscopy (LT-STM) to study the interaction of syngas with well-defined Co nanoparticles grown onto Cu {111}, an inert metal for FTS. Hydrogen adsorbs dissociatively on the Co surfaces, resulting in three unique coverage-dependent phases. We demonstrate that these phases can resolve crystal packing ambiguities of the underlying Co nanoparticles, a question that has been debated in the literature. Simultaneous exposure of the Co to H₂ and CO results in segregated islands of the adsorbates on the nanoparticle surface at 80 K, and we propose that atomic H blocks CO adsorption, causing the build-up of CO at the nanoparticle step edges. With increasing CO coverage, a two-dimensional phase compression of H by CO is observed, providing the *first direct* visualization of this phenomenon in a catalytically relevant system. Our data suggest that FTS reactivity may be dominated by the interface length between the adsorbates and be subject to unforeseen kinetic restraints as a function of particle size.

12:27PM Q34.00005 Cooperative Effects in the Oxidation of CO by Palladium Oxide Cations¹, ARTHUR C. REBER, SHIV N. KHANNA, Department of Physics, Virginia Commonwealth University, ERIC C. TYO, CHRISTOPHER L. HARMON, A. WELFORD CASTLEMAN JR., Departments of Chemistry and Physics, Penn. State University — It is shown that cooperative reactivity plays an important role in the oxidation of CO to CO₂ by palladium oxide cations. Comprehensive studies including guided-ion-beam mass spectrometry and theoretical investigations reveal the reaction products and profiles of PdO₂⁺ and PdO₃⁺ with CO through oxygen radical centers and dioxygen complexes bound to the Pd atom. We find that the O radical centers are more reactive than the dioxygen complexes, and experimental evidence of both direct and cooperative CO oxidation with the adsorption of two CO molecules are observed. The binding of multiple electron withdrawing CO molecules is found to increase the barrier heights for reactivity due to decreased binding of the secondary CO molecule, however reactivity is enhanced by the increase in kinetic energy available to hurdle the barrier. We examine the effect of oxygen sites, cooperative ligands, and spin including two-state reactivity.

¹This material is based upon work supported by the Air Force Office of Scientific Research (AFOSR) Award: FA9550-08-01-0400.

12:39PM Q34.00006 Design of nanocatalysts for improved selectivity and stability, FRANCISCO ZAERA, University of California — Several examples from ongoing work in our laboratory on the use of self-assembly to prepare heterogeneous catalysts with novel architectures will be discussed in this presentation. In one case, catalysts consisting of dispersed platinum metal nanoparticles with narrow size distributions and well-defined shapes were prepared and tested for the selective promotion of carbon-carbon double-bond cis-trans isomerization reactions in olefins. It was shown that the selective formation of the cis isomer could be controlled by using tetrahedral particles with exposed (111) facets. In a second example, catalysts based on small platinum nanoparticles of well-defined sizes were made by using dendrimers as scaffolding structures. The organic framework in that case can provide new functionality, including chirality as a way to introduce enantioselectivity. The third example involves the control of metal nanoparticle sintering by covering those with a layer of mesoporous silica grown on top. The final case to be discussed is one where yolk@shell metal-semiconductor constructs are being developed for increase stability in oxidation and photocatalytic applications.

1:15PM Q34.00007 Towards Catalysis by Gold Clusters: reaction cycles and poisons, ELIZABETH C. BERET, LUCA M. GHIRINGHELLI, MATTHIAS SCHEFFLER, Fritz-Haber-Institut, D-14195, Berlin — Nanosized gold particles are good catalysts in a variety of oxidation reactions. These reactions, for which oxidation of CO to CO₂ serves as a paradigm, imply a transition in the total spin and therefore do not occur spontaneously in the gas phase. In the catalytic process, the catalyst clusters are exposed to an atmosphere of gas-phase O₂ and CO reactants at finite temperature and pressure. We have thus modeled free gold clusters in contact with an atmosphere composed of O₂ and CO by means of DFT calculations (PBE functional), and accounted for both temperature and pressure effects employing *ab initio* atomistic thermodynamics. On the basis of this analysis, we could recognize the thermodynamic driving force of the catalytic CO oxidation process and single out the possible (*p*, *T*)-dependent reaction cycles and those paths leading to stable structures that poison the catalytic process. This as a useful (exploratory) theoretical step, before taking chemical reaction kinetics into consideration. In the proposed reaction paths, the total spin is conserved in each elementary step, and it is the adsorption of an incoming O₂ molecule that drives the catalyst cluster from the singlet to the triplet spin state, and *vice versa*.

1:27PM Q34.00008 Breaking Carbonyl Bonds in Formaldehyde via Complementary Active Sites¹, SHIV N. KHANNA, ARTHUR C. REBER, Department of Physics, Virginia Commonwealth University, W. HUNTER WOODWARD, JORDAN C. SMITH, A. WELFORD CASTLEMAN JR., Departments of Chemistry and Physics, Pennsylvania State University — We had recently shown that the complementary active sites in homonuclear clusters may stimulate the breaking of polar bonds enabling an atomic level control of reactivity. However, such bond cleavage has only been observed in hydroxyl bonds. In this work, we present experimental and theoretical evidence that demonstrates that the stronger C=O carbonyl bond of formaldehyde is split by complementary active sites on size selective aluminum cluster anions. The resonance structure in which the carbonyl is reduced to a single bond is stabilized by the paired active sites establishing the potential use of these geometrically driven centers in devising precursors for synthesizing chemicals or radicals that might find use in production of fine chemicals.

1:39PM Q34.00009 Morphological, electronic, and catalytic properties of Pt nanoclusters on defective graphene, IOANNA FAMPIOU, ASHWIN RAMASUBRAMANIAM, University of Massachusetts Amherst — The synthesis of well dispersed, size-controlled Pt nanoclusters on carbon supports is highly desirable since such clusters have been shown to possess enhanced catalytic activity and selectivity in a variety of chemical reactions. However, these nanoclusters interact rather weakly with defect-free carbon supports and can coarsen over time leading to loss of surface area and thence catalytic activity. Defects in carbon supports play an important role in enhancing Pt-carbon bonding, thereby reducing the propensity for cluster coalescence. Using a combination of density functional theory and empirical potential simulations, we examine the interaction of Pt nanoclusters with point defects in graphene. We focus on the role of the support defects in controlling the morphology, electronic structure, and CO-tolerance of Pt nanoparticles. Our results suggest possible avenues for controlling the dispersion and activity of Pt nanoclusters on carbon supports via defect engineering.

1:51PM Q34.00010 Controlled Catalytic Properties of Platinum Clusters on Strained Graphene, GYUBONG KIM, Korea Institute of Science and Technology, YOSHIYUKI KAWAZOE, Tohoku University, KWANG-RYEOL LEE, Korea Institute of Science and Technology — We employed biaxially strained graphene as the supporting material for Pt clusters (Pt_x , $x=1, 4$ or 6) and studied the molecular adsorption behaviors of H_2 , CO and OH on the cluster using ab initio calculations. It was shown that the applied strain enhances binding of the Pt cluster on the graphene, which lowers the average energy of Pt d electron (d-band center). The binding energies of H_2 , CO and OH on Pt_1 /graphene are strongly correlated with the d-band center modulated by the graphene strain. The calculations with small Pt clusters (Pt_4 and Pt_6) also show that the d-band center is a substantial factor for the catalytic activity of the Pt_x /graphene system. We also found that the stability of the Pt clusters was enhanced by applying the strain on the graphene support.

2:03PM Q34.00011 Composition-Dependent Size and Shape Changes of Pt-Rh Alloy Nanoparticles on $\alpha-Al_2O_3(0001)$ during CO Oxidation Reactions¹, UTA HEJRAL, PATRICK MUELLER, University of Siegen - Germany, OLIVIER BALMES, DIEGO PONTONI, European Synchrotron Radiation Facility (ESRF) - France, ANDREAS STIERLE, University of Siegen - Germany — Pt-Rh nanoparticles are widely used in chemical industry and in automotive exhaust control where they catalyze among other reactions the oxidation of CO. Major attention has in recent years been paid to the study of alloy nanoparticles with the aim to identify systems that allow to control the catalyst selectivity and to enhance its activity and lifetime [1]. Sintering is regarded as one of the major causes of catalyst deactivation and it is of utmost scientific and economic interest to find ways to prevent it. Here we present concentration-dependent size and shape changes of epitaxial Pt-Rh alloy nanoparticles on $\alpha-Al_2O_3(0001)$ substrates observed in-situ during CO oxidation at near atmospheric pressures. The experiments were carried out in a flow-reactor at the high energy beamline ID15A (ESRF) by means of grazing incidence x-ray diffraction ($E=78.8$ keV), x-ray reflectivity measurements and in-situ mass-spectrometry [2]. During the experiments the O_2 pressure ranged between 0 and 14 mbar while the temperature and CO pressure were kept at 550 K and 20 mbar, respectively. Our results demonstrate that a higher Rh concentration reduces sintering significantly.

Wednesday, February 29, 2012 11:15AM - 2:03PM – Session Q35 DCP: Focus Session: DFT VI: New Functional Developments 107B

11:15AM Q35.00001 Some thoughts about old and new density functionals, MIGUEL MARQUES, LPMCEN, Université Lyon I and CNRS — The only theoretical approximation that lies at the heart of DFT appears is the (in)famous exchange-correlation functional. It is therefore not surprising that this quantity has been extensively studied, and that more than 150 different approximations have been put forward in the past 50 years. In this talk I will show some results concerning different families of functionals. The first concerns hybrid functionals, and in particular the role of the mixing parameter. This is commonly assumed to be fixed at a value around 0.2-0.3. However, by noting the similarities between the hybrid functionals and screened Hartree-Fock and ultimately GW theories, we can relate this parameter to the screening properties of the system. In this way we can build a recipe that allows for a considerable improvement on the results obtained by traditional hybrid functionals for solids. As a second topic, I will discuss if it is possible to completely get rid of the Slater integrals present in both Hartree-Fock, hybrid functionals or OEP approaches, and anyway get a proper description of the exchange in terms of reduced densities. I will pay particular attention to the new meta-GGA functionals for the exchange potentials, like, e.g., the Becke-Johnson potential and its more recent variations, like the Tran and Blaha or the Rasanen, Pittalis, and Proetto functionals.

11:51AM Q35.00002 Self-interaction corrected Kohn–Sham potentials, VIKTOR STAROVEROV, Department of Chemistry, The University of Western Ontario, London, Ontario N6A 5B7, Canada — Exchange-correlation potentials derived from conventional density-functional approximations fail to exhibit the slow Coulombic decay—a problem that is related to the self-interaction error in the potential. We show how the self-interaction error of standard semilocal approximations can be effectively reduced by employing modified electron densities to construct the corresponding Kohn–Sham potentials. Using this correction scheme in the framework of adiabatic time-dependent density-functional theory we obtain significantly improved electronic excitation energies, especially for Rydberg states.

12:03PM Q35.00003 Density-on-wave-function mapping beyond the Hohenberg-Kohn theorem, KLAUS CAPELLE, Federal University of ABC (UFABC) — Density-functional theory is based on the Hohenberg-Kohn theorem, establishing a one-on-one mapping between ground-state densities and wave functions. That theorem does not, however, make a direct statement on whether two wave functions that are in some sense close are mapped on two densities that are also close, and vice versa. In this work, a metric is defined that allows to quantify the meaning of “close” in the preceding sentence. This metric stratifies Hilbert space into concentric spheres on which maximum and minimum distances between states can be defined and geometrically interpreted. Numerical calculations for the Helium atom, Hooke's atom and a lattice Hamiltonian show that the mapping between densities and ground states, which is highly complex and nonlocal in the coordinate description, in metric space becomes a monotonic and nearly linear mapping of vicinities onto vicinities. In this sense, the density-on-wave-function mapping is not only simpler than expected; it is as simple as it could be.

I. D'Amico, J. P. Coe, V. V. França, and K. Capelle, Phys. Rev. Lett. 106, 050401 (2011) and Phys. Rev. Lett. 107, 188902 (2011). See also E. Artacho, Phys. Rev. Lett. 107, 188901 (2011).

12:15PM Q35.00004 Finding density functionals with machine learning¹, JOHN SNYDER, University of California, Irvine, MATTHIAS RUPP, Eidgenössische Technische Hochschule, Zurich, KATJA HANSEN, KLAUS MUELLER, Technische Universität, Berlin, KIERON BURKE, University of California, Irvine — Using standard methods from machine learning, we introduce a novel technique for density functional approximation. We use kernel ridge regression with a Gaussian kernel to approximate the non-interacting kinetic energy of 1-dimensional multi-electron systems. With fewer than 100 training densities, we can achieve mean absolute errors of less than 1 kcal/mol on new densities. We determine densities for which our new functional will fail or perform well. Finally, we use principle component analysis to extract accurate functional derivatives from our functional, enabling an orbital-free minimization of the total energy to find a self-consistent density. This empirical method has two parameters, set via cross-validation, and requires no human intuition. In principle, this general technique can be extended to multi-dimensional systems, and can be used to approximate exchange-correlation density functionals.

12:27PM Q35.00005 New Density Functionals with Broad Applicability in Chemistry (SOGGA11, SOGGA11-X, M11, M11-L) and Approaches to Open-Shell DFT¹, DONALD TRUHLAR, University of Minnesota — The accuracy of density functional theory for practical applications is determined by the quality of the necessarily approximate exchange-correlation functional (“density functional”) being used, and the goal of functional development in chemical physics is to obtain a functional that is accurate for a broad range of chemistry and physics. In our work we consider molecular structures and solid-state lattice constants and band gaps, but we emphasize energetics for main-group and transition-metal chemistry, including thermochemistry and barrier heights, noncovalent interaction energies, and excitation energies. This lecture will discuss four new density functionals, each optimized to give the best across-the-board performance for a broad range of chemistry in their class of functional: SOGGA11, a generalized gradient approximation (GGA); SOGGA11-X, a global hybrid GGA; M11: a range-separated hybrid meta-GGA, and M11-L, a meta-GGA. SOGGA11 and M11-L are local functionals, and SOGGA11-X and M11 include some nonlocal Hartree-Fock exchange. To the extent that time permits, I may also discuss recent progress in the treatment of open-shell systems by density functional theory, including time-dependent DFT, open-shell SCF, and noncollinear DFT. This invited lecture is based on collaborative research carried out with Roberto Peverati, Sijie Luo, Ke Yang, Boris Averkiev, Yan Zhao, and Rosendo Valero.

¹This work is supported in part by the AFOSR and the NSF.

1:03PM Q35.00006 Self-Interaction Free and Analytic Treatment of the Coulomb Energy in Kohn-Sham Density Functional Theory¹, MARKUS DAENE, ANTONIOS GONIS, Lawrence Livermore National Laboratory, DON M. NICHOLSON, G. MALCOLM STOCKS, Oak Ridge National Laboratory — We have developed a new treatment of the LDA functional in Kohn-Sham density functional theory which is expressed in terms of the pair density of a non-interacting system of particles, thus avoiding from the outset self-interaction effects. The pair density is expressed explicitly in terms of the density using a orthonormal and complete basis expressed as a functional of the density. This allows its functional differentiation with respect to the density and therefore the determination of the self-interaction free Coulomb potential by analytic means. The method is illustrated with numerical results for the atom series.

1:15PM Q35.00007 Electronic structure via potential functional approximations, ATTILA CANGI, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany, DONGHYUNG LEE, Department of Chemistry, Rice University, 6100 Main Street, Houston, TX 77005-1892, USA, PETER ELLIOTT, Department of Physics and Astronomy, Hunter College and the City University of New York, 695 Park Avenue, New York, New York 10065, USA, KIERON BURKE, Department of Chemistry, University of California, 1102 Natural Sciences 2, Irvine, California 92697-2025, USA, E.K.U. GROSS, Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle (Saale), Germany — The universal functional of Hohenberg and Kohn is given as a coupling-constant integral over the density as a functional of the potential [1]. Conditions are derived under which potential-functional approximations are variational. Construction via this method and imposition of these conditions are shown to greatly improve the accuracy of the non-interacting kinetic energy needed for orbital-free Kohn-Sham calculations. This result provides a direct route to a self-consistent, orbital-free theory for the electronic structure of matter within the Kohn-Sham framework. It solely requires an approximation to the non-interacting density as a functional of the potential, which, so far, has been derived for simple systems [2,3].

1:27PM Q35.00008 Self-Consistent Random Phase Approximation, DANIEL ROHR, Rice University, Houston, TX, MARIA HELLGREN, E.K.U. GROSS, Max-Planck-Institute, Halle, Germany — We report self-consistent Random Phase Approximation (RPA) calculations within the Density Functional Theory. The calculations are performed by the direct minimization scheme for the optimized effective potential method developed by Yang et al. [1]. We show results for the dissociation curve of H_2^+ , H_2 and LiH with the RPA, where the exchange correlation kernel has been set to zero. For H_2^+ and H_2 we also show results for RPAX, where the exact exchange kernel has been included. The RPA, in general, over-correlates. At intermediate distances a maximum is obtained that lies above the exact energy. This is known from non-self-consistent calculations and is still present in the self-consistent results. The RPAX energies are higher than the RPA energies. At equilibrium distance they accurately reproduce the exact total energy. In the dissociation limit they improve upon RPA, but are still too low. For H_2^+ the RPAX correlation energy is zero. Consequently, RPAX gives the exact dissociation curve. We also present the local potentials. They indicate that a peak at the bond midpoint builds up with increasing bond distance. This is expected for the exact KS potential.

1:39PM Q35.00009 On the Hohenberg-Kohn and Levy-Lieb Constrained Search Proofs of Density Functional Theory, VIRAH T SAHNI, Brooklyn College CUNY, XIAO-YIN PAN, Ningbo University — In HK, a 1-1 relationship between the density $\rho(\mathbf{r})$ and the potential $v(\mathbf{r})$ is established. (The relationship between $v(\mathbf{r})$ and the ground state Ψ is 1-1.) The proof, valid for v -representable densities, shows $\rho(\mathbf{r})$ to be a basic variable. The LL proof is independent of $v(\mathbf{r})$, and is valid for N -representable densities. In¹ we have proved that in an external magnetic field $\mathbf{B}(\mathbf{r}) = \nabla \times \mathbf{A}(\mathbf{r})$, there is a 1-1 relationship between $\{\rho(\mathbf{r}), \mathbf{j}(\mathbf{r})\}$, with $\mathbf{j}(\mathbf{r})$ the physical current density, and the potentials $\{v(\mathbf{r}), \mathbf{A}(\mathbf{r})\}$. (The relationship between $\{v(\mathbf{r}), \mathbf{A}(\mathbf{r})\}$ and Ψ is *many-to-one*.) This proves that $\{\rho(\mathbf{r}), \mathbf{j}(\mathbf{r})\}$ are the basic variables. The LL proof independent of $\{v(\mathbf{r}), \mathbf{A}(\mathbf{r})\}$ follows readily. However, such a proof also follows if $\{\rho(\mathbf{r}), \mathbf{j}_p(\mathbf{r})\}$, with $\mathbf{j}_p(\mathbf{r})$ the paramagnetic current density, are considered the basic variables. As such knowledge of the basic variables as determined via HK is a pre-requisite to any LL type proof.

1:51PM Q35.00010 Efficient van der Waals energy calculations via a continuum mechanics approach, TIM GOULD, JOHN F. DOBSON, Qld Micro- and Nanotechnology Centre, Griffith University, Nathan, Qld 4111, Australia, ILYA V. TOKATLY, IKERBASQUE, Basque Foundation for Science, E-48011, Bilbao, Spain — Recent developments in continuum mechanics (CM) [Tao *et al*, PRL103,086401] enable the calculation of density response functions from groundstate properties only. Using the direct Random Phase Approximation (dRPA) we develop this CM approach into a third-rung van der Waals energy functional, which we dub the CM-dRPA. The functional requires as input the groundstate Kohn-Sham potential $V^{\text{KS}}(\vec{r})$, density $n^0(\vec{r})$ and a kinetic stress tensor $T^0(\vec{r})$ defined via $T_{\mu\nu}^0 = \text{Re} \sum_{i\text{occ}} \psi_{i,\mu}^* \psi_{i,\nu} - n_{\mu,\nu}^0/4$ where ψ_i is an orbital. We present efficient algorithmic schemes for its evaluation in bulk and molecular systems using the full eigen-solutions of the bare CM equation and a second, simpler evaluation to find the interacting eigenvalues. These eigen-solutions are then used to calculate the correlation energy via a simple summation. The CM-dRPA is *significantly* faster than a full dRPA calculation in systems with many electrons. We then apply the CM-dRPA functional to metallic, slab-like 2D-homogeneous jellium systems and periodic solids, with good results for vdW dispersion. In the metallic case most efficient vdW functionals would fail qualitatively.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q36 DCP: Water and Ice 107C

11:15AM Q36.00001 Ionic force field optimization and modified ion-pair mixing rules, MARIA FYTA, Physics Department (T37) Technical University of Munich, ROLAND R. NETZ, Fachbereich Physik, Freie Universitaet Berlin, 14195 Berlin, Germany — We propose an optimization scheme to obtain good ionic force fields for classical simulations of salt solutions, also of biological relevance. Our work is based on Molecular Dynamics simulations with explicit (SPC/E) water for different halide and alkali ions forming salt solutions at finite ion concentration. The force field derivation technique we propose is based on a simultaneous optimization of single-ion and ion-pair properties and the determination of the cation-anion interaction parameters (traditionally given by the mixing rules). From the finite-concentration simulations, thermodynamic properties of the salt solutions are derived, using the Kirkwood-Buff theory of solutions, and compared to relevant experimental data. For the rather size-symmetric salt solutions involving bromide and chloride ions, this scheme using the standard mixing rules works fine. For the iodide and fluoride solutions, corresponding to the largest and smallest anion we have considered, a rescaling of the mixing rules was necessary. In this respect, we have introduced scaling factors for the cation-anion Lennard-Jones interaction that quantify deviations from the standard mixing rules. We discuss the efficiency and complications of the proposed ionic force field optimization scheme.

11:27AM Q36.00002 Effects of Applied Electric Field on the Dynamics of Nano-Confined Water¹, SOULEYMANE DIALLO, EUGENE MAMONTOV, Spallation Neutron Source, NOBUO WADA, Nagoya University — We present quasi-elastic neutron scattering measurements of the proton diffusion in water confined in silica nanopores (FSM), with average pore diameters of 16 Å and 39 Å. The measurements were performed on the high resolution backscattering silicon spectrometer (BaSiS) at the Spallation Neutron Source (SNS). From the data, we determine the self diffusion constants, and the translational and rotational relaxation times, as a function of temperature from 300 K down to 200 K. We observe a significant slowing down of the proton diffusion as the temperature is lowered, and a remarkable effect of confinement of the translational motion. Recent results on the effects of applied electrical field on these dynamical processes will be reported.

¹Work at ORNL and SNS is sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, US DOE.

11:39AM Q36.00003 Competing Nuclear Quantum Effects and van der Waals Interactions in Water, JEFFREY MCMAHON, Department of Physics, University of Illinois, Urbana-Champaign, IL 61801, MIGUEL MORALES, Lawrence Livermore National Laboratory, Livermore, California 94550, USA, DAVID CEPERLEY, Department of Physics, University of Illinois, Urbana-Champaign, IL 61801 — Water plays a central role in many scientific disciplines, and a number of studies have been performed to understand its properties. However, providing an accurate ab initio description is a significant challenge, and because of this, many of water's properties remain elusive. In particular, the description of hydrogen bonding and the importance of van der Waals (vdW) interactions and nuclear quantum effects are still matters of debate. Recent computational advancements have been made that allow for the accurate and efficient modeling of such effects. We present results from path integral molecular dynamics simulations based on density functional theory employing exchange and correlation functionals capable of accounting for vdW interactions (so-called vdW-DF, vdW-DF2, and optB88-vdW). We demonstrate that, contrary to expectation, the interaction between nuclear quantum effects and vdW interactions hardens the structure of water. These results suggest that ad hoc methods to account for these effects, such as temperature rescaling of simulations employing classical nuclei, are insufficient to describe water, and that fully ab initio calculations must be performed. We discuss the implications of these results for understanding the local structure and hydrogen bonding in water.

11:51AM Q36.00004 BSE/GW calculations of liquid and solid H₂O¹, JOHN VINSON, J.J. KAS, F.D. VILA, J.J. REHR, University of Washington, E.L. SHIRLEY, NIST, Gaithersburg MD — We have calculated both the UV/VIS and Oxygen K-edge x-ray spectra of model ice and water systems within many-body perturbation theory using state-of-the-art Bethe-Salpeter equation (BSE) and GW self-energy approximations [1], as implemented in the valence- and core-excitation codes OCEAN and AI2NBSE [2]. While the various phases of crystalline ice have well-characterized structures, the local environment and fluctuations of liquid water remain subjects of debate. Due in part to limitations of previous theoretical models, the interpretation of experimental probes has been controversial. We find that the BSE approach, which provides an accurate treatment of core-hole interactions, is vital for a quantitative agreement between experiment and theory. Likewise the effects of self-energy corrections within the GW approximation are needed to explain the observed band-stretching and damping of the spectra. Prospects for further improvements are briefly discussed.

12:03PM Q36.00005 Effect of hydrogen bond cooperativity on the phase behavior of water, KEVIN STOKELY, Boston University Physics Department — Four scenarios have been proposed for the low-temperature phase behavior of liquid water, each predicting different thermodynamics. The physical mechanism which leads to each is debated. Moreover, it is still unclear which of the scenarios best describes water, as there is no definitive experimental test. Here we address both open issues by analyzing a microscopic cell model within a mean-field limit. We show that a common physical mechanism underlies each of the four scenarios, and that two key physical quantities determine which of the four scenarios describes water: (i) the strength of the directional component of the hydrogen bond and (ii) the strength of the cooperative component of the hydrogen bond. The four scenarios may be mapped in the space of these two quantities. Using estimates from experimental data for H bond properties, the model predicts that the low-temperature phase diagram of water exhibits a liquid-liquid critical point at positive pressure.

12:15PM Q36.00006 Structure and dynamics of the liquid water-ZnO(10 $\bar{1}$ 0) interface from first principles, GABRIELE TOCCI, ANGELOS MICHAELIDES, London Centre for Nanotechnology & University College London, Department of Chemistry — Liquid water-metal oxide interfaces are of fundamental and technological interest. In this context, the water-ZnO(10 $\bar{1}$ 0) interface is an extensively studied system, which is also relevant for instance to the field of heterogeneous catalysis and photocatalysis. Yet, whether or not water dissociates at this surface at coverages exceeding one monolayer is still a matter of debate. Likewise questions about proton transfer to the surface, water diffusion and rearrangement within the hydrogen-bonded network remain unanswered. Here we report the first density functional theory (DFT) molecular dynamics study of a liquid water film on ZnO(10 $\bar{1}$ 0) and of water at monolayer coverages. The water structure obtained for the first layer in the liquid simulation differs quite significantly from that at monolayer coverage. Hydrogen bonding between the first layer and the water overlayer plays a crucial role in the stabilisation of the new adsorption structure. Rapid proton transfer and rattling within the hydrogen bonding network at the interface is observed and analysed in detail. On the whole, this study provides considerable new insight into water structure and dynamics and proton transfer at ZnO(10 $\bar{1}$ 0) and in the field of liquid water-metal oxides interfaces in general.

12:27PM Q36.00007 Density fluctuations and dielectric constant of water in low and high density liquid states, ERIK LASCARIS, Boston University, CUI ZHANG, GIULIA A. GALLI, University of California, Davis, GIANCARLO FRANZESE, Universitat de Barcelona, H. EUGENE STANLEY, Boston University — The hypothesis of a liquid-liquid critical point (LLCP) in the phase diagram of water, though first published many years ago, still remains the subject of a heated debate. According to this hypothesis there exists a critical point near $T \approx 244$ K, and $P \approx 215$ MPa, located at the end of a coexistence line between a high density liquid (HDL) and a low density liquid state (LDL). The LLCP lies below the homogenous nucleation temperature of water and it has so far remained inaccessible to experiments. We study a model of water exhibiting a liquid-liquid phase transition (that is a liquid interacting through the ST2 potential) and investigate the properties of dipolar fluctuations as a function of density, in the HDL and LDL. We find an interesting correlation between the macroscopic dielectric constants and the densities of the two liquids in the vicinity of the critical point, and we discuss possible implications for measurements close to the region where the LLCP may be located.

12:39PM Q36.00008 The role of quantum nuclear effects in hydrogen bonded crystals and their calculated NMR shielding constants¹, KJARTAN THOR WIKFELDT, London Centre for Nanotechnology, University College London, CHRIS PICKARD, Department of Physics and Astronomy, University College London, ANGELOS MICHAELIDES, London Centre for Nanotechnology, University College London — Because of its ubiquity in nature the hydrogen atom plays a very important role in computational materials science. As the lightest element, hydrogen nuclei are also the most strongly affected by quantum nuclear effects (QNEs). The path integral (PI) formalism provides a rigorous approach to obtain equilibrium quantum static properties, but PI simulations in conjunction with electronic structure calculations are rarely used due to high computational requirements. This contribution will discuss *ab initio* PI simulations aimed at elucidating the role of QNEs in hydrogen bonded crystals and how these impact upon experimental observables such as nuclear magnetic resonance (NMR) shielding constants and chemical shifts. We find that *ab initio* PI simulations improve the agreement with experimental chemical shifts compared to simulations with classical nuclei and that the influence of QNEs is very sensitive to the strength of the hydrogen bonds in the crystal.

12:51PM Q36.00009 Selective mode analysis of nuclear quantum effects for liquid water using non-Markovian thermostats, SRIRAM GANESHAN, MARIVI FERNÁNDEZ-SERRA, Stony Brook University — Simulating nuclear quantum effects in liquid water using both DFT and force fields has been an active area of research in recent years. Recently, Ceriotti et. al [1] introduced a comprehensive framework to use a custom-tailored Langevin equation with correlated-noise in the context of molecular-dynamics simulations. One of the interesting applications of these thermostats is that, such a framework can be used to selectively damp normal modes whose frequency falls within a prescribed range. In this work we study how the flexible force field models respond to the selective mode thermostating using the delta-like memory kernels. We apply this delta thermostat to the molecular dynamics of TIP4P/F water force field [2], a model explicitly fitted with the lack of zero point ionic vibrations. We address the question of whether thermostating each mode to its zero point temperature is enough to generate the nuclear quantum effects in water and similar systems. This work also provides a way to identify the dominant modes for which the quantum effects are important. [1] M. Ceriotti, G. Bussi, and M. Parrinello, Phys. Rev. Lett. 103, 030603 (2009). [2] S. Habershon, T. E. Markland, and D. E. Manolopoulos, J. Chem. Phys. 131, 024501 (2009).

1:03PM Q36.00010 ABSTRACT WITHDRAWN —

1:15PM Q36.00011 Anomalous nuclear quantum effects in ice¹, BETÜL PAMUK, Stony Brook University, JOSE M. SOLER, Universidad Autonoma de Madrid, PHILIP B. ALLEN, MARIVI FERNÁNDEZ-SERRA, Stony Brook University — The lattice parameters of light (H₂O) and heavy (D₂O) ice at 10 K differ by 0.09%. [1] The larger lattice constant is that of the heavier isotope. This isotope shift with anomalous sign is linked to the zero point energy of phonons in ice. To determine the origin of this anomaly, we use *ab initio* density functional theory to compute the free energy of ice within the quasiharmonic approximation. As expected, the frozen lattice constant at $T = 0$ K is smaller than the quantum lattice constant, independent of the isotopic substitution. We find that, the heavy isotope D gives more zero point expansion than H, whereas the heavy isotope ¹⁸O gives normal zero point expansion, i.e smaller than ¹⁶O. Relative to the classical result, the net effect of quantum nuclei (H and O) on volume has the conventional (positive) sign at $T = 0$ but it becomes negative above 70 K, indicating that it may be also relevant for liquid water. These results are not reproduced by state of art polarizable empirical potentials. [2] [1] B. K. Röttger et. al., Acta Cryst. B 50, 644-648 (1994). [2] C. P. Herrero and R. Ramírez, J. Chem. Phys. 134, 094510 (2011).

1:27PM Q36.00012 Mechanism of sessile water droplet evaporation, HADI GHASEMI, CHARLES WARD, University of Toronto — The energy transport mechanisms during the evaporation of sessile water droplets have been investigated. Steady-state evaporation experiments were conducted on substrates of Cu, Au(111) and PDMS. The buoyancy-driven convection was suppressed by maintaining the droplets' base temperature just less than 4°C while evaporation cooled the liquid-vapor interface to lower temperatures. The temperature fields were measured in solid (only in Au(111) experiments), liquid and vapor phases. On all three substrates, the energy balance at the liquid-vapor interface showed that thermocapillary convection transported the major portion of the energy required for the evaporation. It transported up to 98% for Cu, up to 87% for Au(111) and up to 72% for PDMS. The role of thermocapillary convection is dominant close to three-phase contact line where most of the evaporation occurs. The experiment on Au (111) showed that of the energy supplied by the solid substrate, only a small portion is transported perpendicular to the solid-liquid interface to the bulk liquid phase. A much larger proportion is conducted through the adsorbed layer at the solid-liquid interface to the three-phase contact line where it is distributed by thermocapillary convection over the liquid-vapor interface and consumed by the phase change process.

1:39PM Q36.00013 Theory and Simulation of Droplet Wetting on Patterned Surfaces¹, AZAR SHAHRAZ, ALI BORHAN, KRISTEN FICHTHORN, Penn State University — Liquid droplets can have multiple wetting modes on physically patterned surfaces, each corresponding to a (meta)stable state. For example, in the Cassie mode, the droplet resides on top of the pattern, while in the Wenzel mode, the droplet penetrates into the pattern. In this work, we study the wetting of patterned surfaces on two different length scales: on the nano-scale using molecular dynamics (MD) and on the macro-scale by minimizing free-energy expressions for various droplet wetting modes. We find that surface topography, size, and initial position of the droplet strongly affect the wetting states and contact angles. In the small Bond-number (small droplet) regime, the surface topography can be scaled by the droplet size, such that the preferred wetting modes and contact angles become independent of droplet size for surfaces with the same scaled topography. MD simulations and theory are in good agreement for small Bond numbers. For moderate to large Bond numbers, gravity plays an important role and MD simulations cannot accurately describe wetting. We create wetting phase diagrams and find that our predictions are in good agreement with experiment. The resulting wetting phase diagrams may serve as a guideline in creating surfaces with desired wettability.

1:51PM Q36.00014 Freezing of Water next to Solid Surfaces Probed Using Sum-Frequency Generation Spectroscopy¹, EMMANUEL ANIM-DANSO, ANISH KURIAN, LIEHUI GE, University of Akron, AZAR ALIZADEH, General Electric, ALI DHINOJWALA, University of Akron — The control of ice formation next to solid surfaces is important in many technological applications such as de-icing for aircrafts and generation of power using wind turbines. We have studied the water-ice transition next to sapphire surface to understand the freezing transition and nucleation of ice. The infrared-visible sum frequency generation spectroscopy is sensitive to the structure and orientation of water molecules next to the solid interface and provides direct information on transition kinetics at the interface. The differences in the nucleation kinetics will be discussed for water in contact with hydrophilic and hydrophobic surfaces.

¹Funded by National Science Foundation

2:03PM Q36.00015 Charging and transmission of low energy particles through Amorphous Solid Water films, YONATAN HOROWITZ, MICHA ASSCHER, Institute of Chemistry, Edmund J. Safra Campus, Givat-Ram, The Hebrew University of Jerusalem, Israel — The interaction of charged particles with condensed water films has drawn significant attention in recent years due to its importance in biological and atmospheric processes. We have studied low energy electrons (3-25 eV) and positive argon ions (55 eV) charging and transmission effects while striking Amorphous Solid Water (ASW) films, 240-1080 ML thick, deposited on ruthenium single crystal substrate, utilizing contact potential difference (CPD) measurements. Charging by both species has shown a plate capacitor-like behaviour. L-defects energetically located just below the conduction band of ice, are likely to stabilize them. The incoming electrons kinetic energy dictates the maximal CPD by retardation of any further electrons from adding up to the already accumulated charges. Electron transmission measurements (0.5-1.5 microamps) have shown that the maximal and stable CPD values were obtained only following a relatively slow change that has developed within the ASW structure. Upon film stabilization, the spontaneous discharge was measured over a period of up to three hours. UV laser photo-emission study of the charged films has suggested that the negative charges tend to reside primarily at the ASW-vacuum interface, in good agreement with a study of charged water nano-clusters.

Wednesday, February 29, 2012 11:15AM - 1:15PM – Session Q37 FIAP FEd: Focus Session: Students, Physics and Innovation 108

11:15AM Q37.00001 Physicists and Economic Growth: Preparing the Next Generation, DOUGLAS ARION, Carthage College — For many years it has been recognized that many physicists are “hidden” – deep in the industrial world or holding positions not named “physicist.” In parallel with this phenomenon is the recognition that many new and innovative product ideas are, in fact, generated by physicists. There are many more ideas that could be brought to market to the benefit of both society and the inventor, but physicists don’t often see themselves as the innovators and inventors that they actually are. A number of education programs have arisen to try to address this issue and to engender a greater entrepreneurial spirit in the scientific community. The *ScienceWorks* program at Carthage College was one of the first to do so, and has for nearly twenty years prepared undergraduate science majors to understand and practice innovation and value creation. Other programs, such as professional masters degrees, also serve to bridge the technical and business universes. As it is no doubt easier to teach a scientist the world of business than it is to teach a businessperson the world of physics, providing educational experiences in innovation and commercialization to physics students can have tremendous economic impact, and will also better prepare them for whatever career direction they may ultimately pursue, even if it is the traditional tenure-track university position. This talk will discuss education programs that have been effective at preparing physics students for the professional work environment, and some of the positive outcomes that have resulted. Also discussed will be the variety of opportunities and resources that exist for faculty and students to develop the skills, knowledge and abilities to recognize and successfully commercialize innovations.

11:51AM Q37.00002 Teaching Innovation Through Undergraduate Research¹, JOHN R. BRANDENBERGER, Department of Physics, Lawrence University, Appleton, WI 54911 — A three-year investigation into the use of ongoing research programs to incubate innovative behavior among undergraduates is underway. Inspired by the 2005 report, *Rising Above the Gathering Storm*, this investigation embraces the claim that more innovation in the US should help arrest the current slippage in US competitiveness. Believing that the development of approaches to teach innovation is timely, physicists at Lawrence University are employing a five-step strategy that spans ten summer weeks to boost innovative attitudes and behavior among physics majors. We are also attempting to inculcate fifteen character traits associated with successful innovators. Recent progress in this investigation will be discussed.

¹Supported by NSF/CCLI/TUES.

12:03PM Q37.00003 The Innovation Hyperlab - Linking Student Innovation at University and Pre-College Levels, RANDALL TAGG, University of Colorado Denver — We have created a laboratory environment to support collaboration between university and pre-college students on innovation and entrepreneurship projects. Called the “Innovation Hyperlab,” this facility is located in a K-12 complex called VistaPEAK schools in Aurora, Colorado. The lab is supported by four elements: a research-grade technical infrastructure of supplies and equipment for technical prototyping, a developing curriculum of “learning modules on demand” for rapid assimilation of technical skills, mentors from universities / medical schools / industry, and innovation projects stimulated by connections with the regional community. A current focus of projects is on medical technology development, linking tenth graders with university undergraduate research students and coordinated with the University of Colorado Denver’s medical school. The Innovation Hyperlab is a work in progress and we will describe challenges that arise in connecting such a collaboration with traditional curriculum at both the university and pre-college levels.

12:15PM Q37.00004 The Physics Entrepreneurship Program - 11 Years of Teaching and Practicing Innovation and Entrepreneurship to Graduate Students and Beyond, EDWARD CANER, Case Western Reserve University — The Physics Entrepreneurship Program (PEP) at Case Western Reserve University is a MS in Physics, Entrepreneurship Track that teaches physics, business, and innovation. PEP admitted its first class in 2000 with the original goal of empowering physicists to be successful entrepreneurs. Since Y2K, much has happened in the world's economies and markets, and we have shifted our goals to include a strong innovation component. For instance, our metrics have changed from "companies created" to "capital raised by our students" (i.e., grants and investment in innovation), which allows our students to participate in an apprentice-type relationship with a more experienced entrepreneur before venturing out on their own (which could take many years before they are ready). We will describe the program, how we teach innovation, student and alumni activities and how difficult it is to operate a sustainable graduate program in this arena.

12:27PM Q37.00005 The Story of a Typical Atypical Graduate of the Physics Entrepreneurship Program at Case Western Reserve University, ADELE LUTA, Adjuvat Biosciences — An entrepreneurial perspective to life can lead to wearing a myriad of hats. Long gone is the stereotypical start-up role. Entrepreneurs now hold physics degrees and procure innovation when called upon. An alumni of the Physics Entrepreneurship Program, Adele Luta has spent the last 5 years at NASA developing an innovative approach to spacesuit sizing. Previously, she founded Eleda International consulting firm and is currently working with Adjuvat Biosciences, on a proprietary treatment pancreatic cancer.

12:39PM Q37.00006 Developing affordable multi-touch technologies for use in physics¹, MARK POTTER, CAROLINA ILIE, DAMIAN SCHOFIELD, DAVID VAMPOLA, State University of New York at Oswego — Physics is one of many areas which has the ability to benefit from a number of different teaching styles and sophisticated instructional tools due to it having both theoretical and practical applications which can be explored. The purpose of this research is to develop affordable large scale multi-touch interfaces which can be used within and outside of the classroom as both an instruction technology and a computer supported collaborative learning tool. Not only can this technology be implemented at university levels, but also at the K-12 level of education. Pedagogical research indicates that kinesthetic learning is a fundamental, powerful, and ubiquitous learning style [1]. Through the use of these types of multi-touch tools and teaching methods which incorporate them, the classroom can be enriched to allow for better comprehension and retention of information. This is due in part to a wider range of learning styles, such as kinesthetic learning, which are being catered to within the classroom.

12:51PM Q37.00007 Wolfram technologies as an integrated scalable platform for interactive learning, VITALIY KAUROV, Wolfram Research — We rely on technology profoundly with the prospect of even greater integration in the future. Well known challenges in education are a technology-inadequate curriculum and many software platforms that are difficult to scale or interconnect. We'll review an integrated technology, much of it free, that addresses these issues for individuals and small schools as well as for universities. Topics include: Mathematica, a programming environment that offers a diverse range of functionality; natural language programming for getting started quickly and accessing data from Wolfram|Alpha; quick and easy construction of interactive courseware and scientific applications; partnering with publishers to create interactive e-textbooks; course assistant apps for mobile platforms; the computable document format (CDF); teacher-student and student-student collaboration on interactive projects and web publishing at the Wolfram Demonstrations site.

1:03PM Q37.00008 Promoting Conceptual Coherence in Quantum Learning through Computational Models¹, HEE-SUN LEE², University of California, Santa Cruz — In order to explain phenomena at the quantum level, scientists use multiple representations in verbal, pictorial, mathematical, and computational forms. Conceptual coherence among these multiple representations is used as an analytical framework to describe student learning trajectories in quantum physics. A series of internet-based curriculum modules are designed to address topics in quantum mechanics, semiconductor physics, and nano-scale engineering applications. In these modules, students are engaged in inquiry-based activities situated in a highly interactive computational modeling environment. This study was conducted in an introductory level solid state physics course. Based on in-depth interviews with 13 students, methods for identifying conceptual coherence as a function of students' level of understanding are presented. Pre-post test comparisons of 20 students in the course indicate a statistically significant improvement in students' conceptual coherence of understanding quantum phenomena before and after the course, Effect Size = 1.29 SD. Additional analyses indicate that students who responded to the modules more coherently improved their conceptual coherence to a greater extent than those who did less to the modules after controlling for their course grades.

Wednesday, February 29, 2012 11:15AM - 2:03PM –
Session Q39 DMP DBIO DPOLY: Focus Session: Materials and Functional Structures for Biological Interfaces - Micro and Nanofluidics 109B

11:15AM Q39.00001 Integration of Materials and Functions in Microfluidic Devices, MARCELLA CHIARI, National Research Council of Italy — The physical and chemical properties of a surface determine how that surface interacts with its surrounding environment. Despite the large number of potential schemes feasible for surface modification, the covalent attachment of polymers remains the most promising approach to tailor important properties of lab-on-chip (LOC) devices such as adhesion, wettability and biocompatibility. This presentation deals with "surface related" issues that must be addressed in the development of LOC systems. An innovative approach that allows the attachment of polymer molecules to surfaces of different composition such as glass, silicon and polymer materials will be presented. Examples of interfaces modified by "smart coatings" able to give an appropriate and predictable response to outside conditions and decorated with biologically relevant biomolecules will be discussed.

11:51AM Q39.00002 Dynamic micromolds to fabricate multi-layered hydrogel microstructures, HALIL TEKIN, Department of Electrical Engineering and Computer Science, MIT, TONIA TSINMAN, Department of Biological Engineering, MIT, JEFFERSON G. SANCHEZ, Department of Chemical Engineering, MIT, BRIANNA J. JONES, Department of Physics, MIT, ROBERT LANGER, Department of Chemical Engineering, MIT, ALI KHADEMHOSEINI, Center for Biomedical Engineering, Brigham and Women's Hospital, Harvard Medical School — Hydrogel microstructures can be used to mimic living systems and create drug carriers. Living materials can be encapsulated within multi-layered microgels to replicate native tissues. Furthermore, multiple drugs can be immobilized within different layers of microgels to create multifunctional drug carriers. Photolithography is a commonly used method to create these multi-layered microgels, but it is not applicable to non-photocrosslinkable materials. Also, conventional micromolding methods do not allow creating multi-layered microgels due to the static environment of the microstructures. Herein, we created dynamic micromolds by exploiting the thermoresponsiveness of poly(N-isopropylacrylamide). These micromolds allowed sequential molding of microgels at different temperatures. Different cell types were spatially immobilized in different layers of microgels to replicate native tissue complexity. Furthermore, fluorescent microbeads were spatially immobilized within different microgel layers to show a concept of drug carriers which could encapsulate various drugs. These dynamic micromolds could be potentially useful in creating multi-layered hydrogel microstructures in order to mimic biological systems and fabricate multifunctional drug carriers.

12:03PM Q39.00003 Implementation of a Peltier-based cooling device for localized deep cortical deactivation during in vivo object recognition testing, KYLE MARRA, Boston College, BRETT GRAHAM, SAMANTHA CAROUSO, DAVID COX¹, Rowland Institute — While the application of local cortical cooling has recently become a focus of neurological research, extended localized deactivation deep within brain structures is still unexplored. Using a wirelessly controlled thermoelectric (Peltier) device and water-based heat sink, we have achieved inactivating temperatures (<20 °C) at greater depths (>8 mm) than previously reported. After implanting the device into Long Evans rats' basolateral amygdala (BLA), an inhibitory brain center that controls anxiety and fear, we ran an open field test during which anxiety-driven behavioral tendencies were observed to decrease during cooling, thus confirming the device's effect on behavior. Our device will next be implanted in the rats' temporal association cortex (TeA) and recordings from our signal-tracing multichannel microelectrodes will measure and compare activated and deactivated neuronal activity so as to isolate and study the TeA signals responsible for object recognition. Having already achieved a top performing computational face-recognition system, the lab will utilize this TeA activity data to generalize its computational efforts of face recognition to achieve general object recognition.

¹Visual Neuroscience Group, Rowland Institute, Harvard University

12:15PM Q39.00004 Droplet Microfluidics for Artificial Lipid Bilayers, SRIKOUNDINYA PUNNAMARAJU, ANDREW STECKL, Nanoelectronics Laboratory, University of Cincinnati — Droplet interface bilayer is a versatile approach that allows formation of artificial lipid bilayer membrane at the interface of two lipid monolayer coated aqueous droplets in a lipid filled oil medium. Versatility exists in the form of voltage control of DIB area, ability of forming networks of DIBs, volume control of droplets and lipid-oil, and ease of reformation. Significant effect of voltage on the area and capacitance of DIB as well as DIB networks are characterized using simultaneous optical and electrical recordings. Mechanisms behind voltage-induced effects on DIBs are investigated. Photo induced effect on the DIB membrane porosity is obtained by incorporating UVC-sensitive photo-polymerizable lipids in DIB. Photo-induced effects can be extended for in-vitro studies of triggered release of encapsulated contents across membranes. A droplet based low voltage digital microfluidic platform is developed to automate DIB formation, which could potentially be used for forming arrays of lipid bilayer membranes.

12:27PM Q39.00005 Density fluctuations in nanochannel-confined DNA, JOSHUA CARPENTER, ALENA KARPUSENKO, CHUNDA ZHOU, SHUANG FANG LIM, JUNHAN PAN, ROBERT RIEHN, Department of Physics, NC State University — The dynamic behavior of a polymer chain in dense solution is typically described within the framework of reptation, which assumes that polymers primarily move along tubes formed by other chains. We have studied the dynamic density fluctuations of single DNA molecules confined to nanofabricated channels that mimic reptation tubes, and found that the classical harmonic spring model yields a satisfactory description. In particular, we have recovered the expected dispersion relationship. By looking at fluctuation amplitudes, we have also found that the description demands a minimum spring length approximately equal to the size of self-avoiding DeGennes blobs.

12:39PM Q39.00006 Extension and Diffusion of DNA in Nanochannels, DOUGLAS TREE, University of Minnesota, YANWEI WANG, Soochow University, KEVIN DORFMAN, University of Minnesota — Nanochannels are an ideal platform for studying the basic physics of confined polymers, using DNA as the model polymer. While the scaling laws for strong (Odijk) and weak (de Gennes) confinement were established decades ago, recent experiments have illuminated the complex physics arising between these limiting cases. We will first present Monte Carlo simulation data on the extension of DNA in nanochannels. Our results provide clear evidence for the existence of two transition regimes between the Odijk and de Gennes regimes, thereby resolving the apparent contradiction between these scaling theories and the corresponding experiments by Austin and coworkers. We will then present results for the diffusivity of DNA in nanochannels and explain their connection to the different regimes of extension. By using Monte Carlo sampling of the Kirkwood diffusivity and a numerical solution for the confined Green's function, we have calculated the diffusivity for DNA contour lengths ranging over three orders of magnitude and nanochannel sizes over two orders of magnitude. By using a DNA model that accurately reproduces the free solution radius of gyration and diffusivity over a range of molecular weights, we can directly connect the simulation data and experiments.

12:51PM Q39.00007 DNA conformation and dynamics in quasi-2D and -1D confinement, YENG-LONG CHEN, Institute of Physics, Academia Sinica — We investigate the structure and correlation length of DNA molecules in sub-100nm quasi-2D slits and 1D square channels. In strong slit confinement, the segmental correlation length of DNA molecules separates into two components – in the confined and unconfined dimensions. In the confined dimension, the segmental correlation length is controlled by the slit height. In the unconfined dimension, the segmental correlation length increases as the slit height decreases. In the nano-channel, segmental correlation length increases beyond the chain contour length as channel height decreases below channel persistence length. We generalize how this affects the entropic elasticity of confined DNA molecules and how it affects chain thermodynamic properties.

1:03PM Q39.00008 Mapping the yeast genome by melting in nanofluidic devices, ROBERT L. WELCH, ILJA CZOLKOS, McGill University, ROB SLADEK, Genome Quebec Innovation Centre, WALTER REISNER, McGill University — Optical mapping of DNA provides large-scale genomic information that can be used to assemble contigs from next-generation sequencing, and to detect re-arrangements between single cells. A recent optical mapping technique called denaturation mapping has the unique advantage of using physical principles rather than the action of enzymes to probe genomic structure. The absence of reagents or reaction steps makes denaturation mapping simpler than other protocols. Denaturation mapping uses fluorescence microscopy to image the pattern of partial melting along a DNA molecule extended in a channel of cross-section ~100nm at the heart of a nanofluidic device. We successfully aligned melting maps from single DNA molecules to a theoretical map of the yeast genome (11.6Mbp) to identify their location. By aligning hundreds of molecules we assembled a consensus melting map of the yeast genome with 95% coverage.

1:15PM Q39.00009 Spatially Varying Nanoconfinement as a Probe of Polymer Physics, ALEXANDER KLOTZ, WALTER REISNER, McGill University — Complex nanofluidic systems have the capability to unveil a rich landscape of new polymer physics. One-dimensional channels and two-dimensional slits have been used for precise measurements of persistence length and to verify scaling laws. Recently, devices with spatially varying confinement have been used to gain further control over single molecule polymer conformation. We use a system consisting of a nanofluidic slit embedded with a lattice of pits acting as entropic traps. Single DNA polymers in this system self-organize into discrete conformational states. We have shown that this system can be used to define stable DNA configurations at equilibrium and to fine-tune diffusion to a local minimum corresponding to stable conformational states. Measurements of mean occupancy with varying device parameters can be fit to theory, giving information about the confinement free energy of DNA in a nanoslit (a subject of controversy) and the strength of excluded volume interactions. Measurements of the excluded volume interaction provide information about the strength of intersegmental repulsive electrostatic interactions, quantified by the notion of effective width. The scaling of width with respect to salt concentration is observed in single DNA molecules for the first time.

1:27PM Q39.00010 The Nanofluidic Staircase: A Brownian Motor for Polymer Characterization and Transport, FREDERICK PHELAN JR., National Institute of Standards and Technology (NIST), CHRISTOPHER FORREY, Food and Drug Administration (FDA), JON GEIST, SAMUEL STAVIS, ELIZABETH STRYCHALSKI, National Institute of Standards and Technology (NIST) — A coarse-grained molecular dynamics simulation is used to study the motion of a polymer chain in a nanofluidic staircase (Stavis et al., Nanotechnology, 20(16), 2009), a device which consists of a collection of nanoslits of increasing depth arranged in step-like fashion in a fluidic channel. The slit depths span the Odijk ($H < L_k$) and de Gennes ($L_k < H < R_g$) regimes, where H is the slit depth, L_k is the polymer Kuhn length, and R_g is the radius of gyration. Simulation results show that the model captures the 1-D biased diffusion of chains from regions of high to low confinement that has been measured in recent experiments (Strychalski et al., 14th Int. Conf. on Min. Sys. for Chem. and Life Sci., 2010). The drift velocity increases with increasing step size but also decays more rapidly; stiffer chains drift at a higher rate than softer chains. For all cases, the overall diffusion rates are higher than those calculated for chains in free solution, indicating that the chains gain a "push" as they migrate through the staircase, a manifestation of entropic forces. The staircase system therefore acts as a Brownian motor, which transfers energy from an external source (the polymer free energy) into directed transport using only thermal fluctuations and the biased structural features of the device.

1:39PM Q39.00011 ABSTRACT WITHDRAWN —

1:51PM Q39.00012 Geometrically induced polarization and alignment of cells on nanopillar arrays, YOLANDA VASQUEZ, MICHAEL BUCARO, BENJAMIN HATTON, JOANNA AIZENBERG, Harvard University — Topological features at the nano and microscale can trigger mammalian cell growth and differentiation. In this work, we describe geometrical tuning of ordered arrays of nanopillars and micropillars that elicit specialized morphologies in adherent cells. Systematic analysis of the effects of the pillar radius, height, and spacing reveals that stem cells assume either flattened, polarized, or stellate morphologies in direct response to interpillar spacing. Notably, on patterns of pitch near a critical spacing ($d_{crit} = 2 \text{ }\mu\text{m}$ for C3H10T1/2 cells), cells exhibit rounding of the cell body, pronounced polarization, and extension of narrow axon-like cell projections aligned with the square or hexagonal lattice of the NP array. This morphology persists for various stem cell lines and primary mesenchymal stem cells. The neuron-like morphological characteristics suggest that NP arrays can be utilized in tissue engineering applications that require directed axon growth. The ability of nano and micropillars to support various morphogenetic trends will allow rational design of scaffolds that may be useful for stem cell lineage specification, formation of patterned neural networks, and enhancement of implant integration with adjoining tissue.

Wednesday, February 29, 2012 11:15AM - 2:15PM —

Session Q40 DBIO GSNP: Focus Session: Systems Biology and Biochemical Networks III 156A

11:15AM Q40.00001 TBD, TING LU, —

11:51AM Q40.00002 Fold-change detection and scalar symmetry of sensory input fields, OREN SHOVAL, Weizmann Institute of Science, LEA GOENTORO, California Institute of Technology, YUVAL HART, AVI MAYO, Weizmann Institute of Science, EDUARDO SONTAG, Rutgers University, URI ALON, Weizmann Institute of Science — Recent studies suggest that certain cellular sensory systems display fold-change detection (FCD): a response whose entire shape, including amplitude and duration, depends only on fold-changes in input, and not on absolute changes. We show that FCD is necessary and sufficient for sensory search to depend only on the spatial profile of the input, and not on its amplitude. Such amplitude scalar symmetry occurs in a wide range of sensory inputs, such as source strength multiplying diffusing chemical fields sensed in chemotaxis, ambient light multiplying the contrast field in vision, and protein concentrations multiplying the output in cellular signaling systems. We present a wide class of mechanisms that have FCD, including certain nonlinear feedback and feedforward loops. In addition, we find that bacterial chemotaxis displays feedback within the present class, and has indeed recently been shown to exhibit FCD. This can explain experiments in which chemotaxis searches are insensitive to attractant source levels. This study thus suggests a connection between properties of biological sensory systems and scalar symmetry stemming from physical properties of their input fields.

12:03PM Q40.00003 Network architectural conditions for prominent and robust stochastic oscillations, JAEWOOK JOO, JINMYUNG CHOI, University of Tennessee — Understanding relationship between noisy dynamics and biological network architecture is a fundamentally important question, particularly in order to elucidate how cells encode and process information. We analytically and numerically investigate general network architectural conditions that are necessary to generate stochastic amplified and coherent oscillations. We enumerate all possible topologies of coupled negative feedbacks in the underlying biochemical networks with three components, negative feedback loops, and mass action kinetics. Using the linear noise approximation to analytically obtain the time-dependent solution of the master equation and derive the algebraic expression of power spectra, we find that (a) all networks with coupled negative feedbacks are capable of generating stochastic amplified and coherent oscillations; (b) networks with a single negative feedback are better stochastic amplified and coherent oscillators than those with multiple coupled negative feedbacks; (c) multiple timescale difference among the kinetic rate constants is required for stochastic amplified and coherent oscillations.

12:15PM Q40.00004 Properties of gene expression including the non-functional binding of transcription factors to DNA, ANAT BURGER, University of California San Diego, ALEKSANDRA WALCZAK, Ecole Normale Supérieure, PETER WOLYNES, Rice University — Many eukaryotic transcription factors bind to DNA sequences with a remarkable lack of specificity. This suggests that non-functional binding between transcription factors and DNA might not have the detrimental effect on regulation one would naively assume results from competition for binding. In fact, if binding to DNA protects transcription factors from degradation, the number and binding affinity of these 'decoy' binding sites should have no influence on the copy number of transcription factors available for regulation. We calculate the influence of adding decoy binding sites on several important aspects of gene expression including the noise, the time to reach steady state, and bimodal switch rates. Analyzing these effects could shed some light on how a gene functions in the 'dressed' environment of a genomic background.

12:27PM Q40.00005 Single promoters as regulatory network motifs, CHRISTOPHER ZOPF, NARENDRA MAHESHWRI, Massachusetts Institute of Technology — At eukaryotic promoters, chromatin can influence the relationship between a gene's expression and transcription factor (TF) activity. This additional complexity might allow single promoters to exhibit dynamical behavior commonly attributed to regulatory motifs involving multiple genes. We investigate the role of promoter chromatin architecture in the kinetics of gene activation using a previously described set of promoter variants based on the phosphate-regulated PHO5 promoter in *S. cerevisiae*. Accurate quantitative measurement of transcription activation kinetics is facilitated by a controllable and observable TF input to a promoter of interest leading to an observable expression output in single cells. We find the particular architecture of these promoters can result in a significant delay in activation, filtering of noisy TF signals, and a memory of previous activation – dynamical behaviors reminiscent of a feed-forward loop but only requiring a single promoter. We suggest this is a consequence of chromatin transactions at the promoter, likely passing through a long-lived “primed” state between its inactive and competent states. Finally, we show our experimental setup can be generalized as a “gene oscilloscope” to probe the kinetics of heterologous promoter architectures.

12:39PM Q40.00006 Towards a principled way of making kinetic models from data¹, STEVE PRESSE, UCSF — Kinetic model extraction from noisy data is the basic route to mechanistic insight in biology. I will show how the tools of Maximum Caliber (the dynamical analog of Maximum Entropy) can be used to infer -and not fit- models in a way which is driven by the structure and limitations of the data. For instance, the typical output of an experiment in systems biology is the stochastic expression of one reporter gene. Master equations used to model the regulatory process underlying the stochastic gene expression require knowledge of a circuit topology and rates. However rates and topology are often fit as these are rarely all independently determinable from the limited data. Our goal is to build a kinetic model from the data available with no adjustable parameter using the tools of Maximum Caliber. We apply our method to infer the statistics of rare stochastic switching events in the genetic toggle switch from fluctuations on shorter measurable timescales. In addition, we discuss how these tools can be used to infer kinetic models from real single molecule data drawn from anomalous folding kinetics of phosphoglycerate kinase and RNA hairpin zipping-unzipping time traces.

¹NIH, FQRNT

12:51PM Q40.00007 Reaction kinetics in the cell membrane: confining domains lead to reaction bursts, ZIYA KALAY, TAKAHIRO FUJIWARA, AKIHIRO KUSUMI, Kyoto University - Inst. for Integrated Cell-Material Sciences — Our goal is to reveal the effects of confining domains such as those observed in cell membranes on the kinetics of reversible reactions in two-dimensions. During the last two decades, single molecule tracking experiments showed that proteins and lipids are temporarily confined in the compartments of a meshwork induced by the actin cytoskeleton, while diffusing laterally in the plasma membrane. It has been clearly demonstrated that the presence of these compartments significantly hinders the diffusion of membrane molecules. Nevertheless, how confinement affects the interaction between membrane molecules and the regulation of signaling has still not been clarified. Using Monte Carlo simulations and the mathematical theory of diffusion, we showed that the presence of compartments leads to reaction bursts, during which the number of reactions an individual molecule experiences rises sharply, but briefly. Surprisingly, we found that the mean reaction rate does not depend on whether compartments exist or not. However, our results show that the variance of the rate depends strongly on the presence of confinement effects, which turns out to be an indicator of a profound change in the temporal pattern of reaction events: bursts of reactions instead of constant but low yield.

1:03PM Q40.00008 Inference of Mechanical Network Parameters in Epithelial Tissue Development, KEVIN CHIOU, Department of Physics, UCSB, LARS HUFNAGEL, EMBL Heidelberg, BORIS SHRAIMAN, KITP, UCSB — Mechanical stress in cells has been linked to biochemical networks that influence cell structure and function. Yet direct *in vivo* measurements of mechanical forces in epithelial tissues remain a serious experimental challenge. I will present an alternative approach based on a computational analysis of high resolution images of epithelial tissues. Assuming that epithelial cell layers are close to mechanical equilibrium, we use the observed geometry of the two dimensional cell array to infer interfacial tensions and intracellular pressures. I will present applications of this mechanical parameter inference algorithm in the context of several developmental processes involving epithelial cell layers.

1:15PM Q40.00009 Regulatory dynamics and stability in discrete and continuous models¹, FAKHTEH GHANBARNEJAD, KONSTANTIN KLEMM, Bioinformatics Group, Institute for Computer Science, University of Leipzig — Biological processes such as cell deviation, cell differentiation and so on are regulated dynamics. These dynamics are often described by continuous rate equations for continuously varying chemical concentrations. Binary discretization of state space and time leads to another class of models, Boolean dynamics, which are dealing with larger systems, higher complexity and less computational details. Here we study the reaction of discrete and continuous dynamics to perturbations. When asking if a gene-regulatory system reproduces a prescribed trajectory despite noise, large perturbations are to be considered in the case of low copy numbers of regulatory molecules and bursty stochastic response. Small perturbations, however, are more appropriate when modelling systems with large copy numbers and an integrative response to filter out bursts. In Boolean networks, the dynamics has been called unstable if flip perturbations lead to damage spreading. We find that this stability classification strongly differs from the stability properties of the original continuous dynamics under small perturbations of the state vector. In particular, random networks of nodes with large sensitivity yield stable dynamics under small perturbations and chaotic regime disappears.

1:27PM Q40.00010 Polarization and molecular information transmission in the cell, ADRIANO VALDEZ-GOMEZ, GUILLERMO RAMIREZ-SANTIAGO, Instituto de Fisica, Universidad Nacional Autonoma de Mexico — During chemotaxis, pseudopodia are extended at the leading edge and retracted at the back of the cell. Efficient chemotaxis is the result of a refined interplay between signaling modules to transmit and integrate spatial information such as PtdIns(3,4,5)P₃. The localization of PtdIns(3,4,5)P₃ is expected to depend on the distributions or activities of PI3Ks, PTEN, and 5-phosphatases. The spatial signals spread relatively slowly so that high local concentrations of PIP₃ in the plasma membrane appear in patches. These gradients induce localization of PIP₃ and PTEN to the front and back of the cell, respectively. To simulate this polarization process that involves the action of seven reaction-channels inside the cell we carried out extensive stochastic simulations using Gilliespie algorithm. The simulations were done on a square cell with ten thousand sites (100 × 100) emulating a square cell with side 10 μm long. We found that there are localized patches of PIP₃ at the active receptors and segregation of PTEN on the opposite side of the cell. When we block the reaction-channel, $PTEN + PIP_3 \rightarrow PIP_2$ that involves the production of PIP₂ we obtained a five-fold increase in the concentration of PIP₃. This finding appears to be consistent with the o

1:39PM Q40.00011 Energy Flow in Neuronal Systems, ZRINKA GREGURIC FERENCEK, JOHN ROBERT CRESSMAN, ZAID OBADA, George Mason University — We will present results from a computational model designed to investigate the physical underpinnings of neuronal systems. Most neuronal models assume that the ionic flow across neuronal membranes is too small to effect the ionic composition inside and outside of cells. However neurons exhibiting high levels of activity can produce ionic redistributions large enough to cause significant changes to cellular excitability. Furthermore, physically-accurate neuronal models must obey conservation of mass and energy. Energy is injected into these cells through the consumption of ATP, stored in electrochemical gradients, and dissipated through ionic flow down these gradients. Our model incorporates essential biological mechanisms required to reproduce this energy flow and storage. We will discuss the advantages and limitations of this dynamic system in the context of neuronal function.

1:51PM Q40.00012 Rhythm-Induced Spike-Timing Patterns Characterized by 1D Firing Map, JAN ENGELBRECHT, RENNIE MIROLLO, Boston College — A basic problem in neuroscience is to understand how the dynamic mechanisms that govern the responses of nerve cells to stimuli, which are both non-linear and noisy, still produce reliable collective activity. We study patterning in the responses of neurons subjected to periodic rhythms. These patterns are governed by simple, low-dimensional mathematical structures independent of modeling detail. We show both theoretically and in whole-cell recordings that the 1D map generated from successive spike times is such a construct. As expected, the stable periodic points of this 1D map cause a neuron's entrainment or phase-locking to a periodic rhythm. But our work has also revealed a complementary and unexpected patterning in the spike-timing of un-entrained neurons in the form of repeated sequences of reliable spike-phase advances, which cannot be characterized simply as a noisy perturbation near the stable periodic points of the noise-free return map. This new patterning appears to require both noise and a sufficiently steep return map.

2:03PM Q40.00013 The Effects of Intrinsic Noise on an Inhomogeneous Lattice of Chemical Oscillators¹, MICHAEL GIVER, Brandeis University, ZAHERA JABEEN, University of Michigan, BULBUL CHAKRABORTY, Brandeis University — Intrinsic or demographic noise has been shown to play an important role in the dynamics of a variety of systems including biochemical reactions within cells, predator-prey populations, and oscillatory chemical reaction systems, and is known to give rise to oscillations and pattern formation well outside the parameter range predicted by standard mean-field analysis. Motivated by an experimental model of cells and tissues where the cells are represented by chemical reagents isolated in emulsion droplets, we study the stochastic Brusselator, a simple activator-inhibitor chemical reaction model. Our work extends the results of recent studies on the zero and one dimensional system to the case of a non-uniform one dimensional lattice using a combination of analytical techniques and Monte Carlo simulations.

Wednesday, February 29, 2012 11:15AM - 2:03PM – Session Q41 DFD: Biofluids 156B

11:15AM Q41.00001 Fool's Gold Footprinting: microfluidic probing of nucleic acids¹, CHRISTOPHER D. JONES, Cornell University, School of Applied & Engineering Physics, JOERG C. SCHLATTERER, Albert Einstein College of Medicine, Department of Biochemistry, MICHAEL BRENOWITZ, Albert Einstein College of Medicine, LOIS POLLACK, Cornell University — We describe a microfluidic device containing a mineral matrix capable of rapidly generating hydroxyl radicals that enables high-resolution structural studies of nucleic acids. Hydroxyl radicals cleave the solvent accessible backbone of DNA and RNA; the cleavage products can be detected with as fine as single nucleotide resolution. Protection from hydroxyl radical cleavage (footprinting) can identify sites of protein binding or the presence of tertiary structure. Here we report preparation of micron sized particles of iron sulfide (pyrite) and fabrication of a microfluidic prototype that together generate enough hydroxyl radicals within 20 ms to cleave DNA sufficiently for a footprinting analysis to be conducted. This prototype enables the development of high-throughput and/or rapid reaction devices with which to probe nucleic acid folding dynamics and ligand binding.

11:27AM Q41.00002 Dislocation dynamics and bacterial growth, ARIEL AMIR, DAVID NELSON, Harvard University — Recent experiments have revealed remarkable phenomena in the growth mechanisms of rod-shaped bacteria: proteins associated with the cell wall growth move at constant velocity in circles oriented approximately along the cell circumference (Garner et al., Science 2011, Domínguez-Escobar et al., Science 2011, Deng et al., PNAS 2011). We view these dislocations in the partially ordered peptidoglycan structure, and study theoretically the dynamics of these interacting dislocations on the surface of a cylinder. The physics of the nucleation of these dislocations and the resulting dynamics within the model show surprising effects arising from the cylindrical geometry, which are predicted to have important implications on the growth mechanism. We also discuss how long range elastic interactions affect the dynamics of the fraction of active dislocations in the environment.

11:39AM Q41.00003 Signal Relay During Cell Migration, CAN GUVEN, Department of Physics, University of Maryland, ERIN RERICHA, School of Medicine, Vanderbilt University, EDWARD OTT, WOLFGANG LOSERT, Department of Physics, University of Maryland — We developed a signal relay model to quantify the effect of intercellular communication in presence of an external signal, during the motion of groups of Dictyostelium discoideum cells. A key parameter is the ratio of amplitude of the cAMP (cyclic adenosine monophosphate) a signaling chemical secreted from individual cells versus the external cAMP field, which defines a time scale. Another time scale is set by the degradation rate of the cAMP. In our simulations, the competition between these two time scales results rich dynamics including uniform motion, as well as streaming and clustering instabilities. The simulations are compared to experiments for a wide range of different external signal strengths for both cells that secrete cAMP and a mutant which cannot relay cAMP. Under different strength of external linear cAMP gradient, the wild type cells form streams and exhibit clustering due to the intercellular signaling through individual cAMP secretion. In contrast, cells lacking signal relay move relatively straight. We find that the model captures both independent motion and the formation of aggregates when cells relay the signal.

11:51AM Q41.00004 Intracellular Transport in Beta Cells - from Anti-Corellated to Active, STANISLAV BUROV, ALI TABELI, AARON DINNER, NORBERT SCHERER, University of Chicago — The intracellular transport along micro-tubules is the main focus of this research. We study the transport of insulin granules inside Beta cells. By developing new technique for the analysis of single 2D trajectories we observe a transition in the transport behavior from anti-correlated to active as a function of time. We further use the observed effect in order to discriminate between possible scenarios of active transport through disordered media as models of efficient intracellular transport.

12:03PM Q41.00005 Acoustic streaming in the cochlea under compressive bone conduction excitation, KATHERINE AHO, MEGHA SUNNY, TAOUFIK NABAT, JENNY AU, CHARLES THOMPSON, University of Massachusetts Lowell — This work examines the acoustic streaming in the cochlea. A model will be developed to examine the steady flow over a flexible boundary that is induced by compressive excitation of the cochlear capsule. A stokeslet based analysis of oscillatory flows was used to model fluid motion. The influence of evanescent modes on the pressure field is considered as the limit of the aspect ratio epsilon approaches zero. We will show a uniformly valid solution in space.

12:15PM Q41.00006 Subtle exchange model of flow depended on the blood cell shape to enhance the micro-circulation in capillary¹, IATNENG CHAN, Physics Group, Faculty of Science and Technology, University of Macau — In general the exchange of gases or other material in capillary system is conceptualized by the diffusion effect. But in this model, we investigate a micro-flow pattern by simulation and computation on a micro-exchange model in which the blood cell is a considered factor, especially on its shape. It shows that the cell benefits the circulation while it is moving in the capillary. In the study, the flow detail near the cell surface is mathematically analyzed, such that the Navier-Stokes equations are applied and the viscous factor is also briefly considered. For having a driven force to the motion of micro-circulation, a breathing mode is suggested to approximately compute on the flow rate in the blood capillary during the transfer of cell. The rate is also used to estimate the enhancement to the circulation in addition to the outcome of diffusion. Moreover in the research, the shape change of capillary wall under pressure influence is another element in the beginning calculation for the effect in the assistance to cell motion.

12:27PM Q41.00007 Modeling fluid diffusion in cerebral white matter with random walks in complex environments, AMICHAÏ LEVY, GABRIEL CWILICH, SERGEY V. BULDYREV, Department of Physics, Yeshiva University, VAN J. WEEDEN, Athinoula A. Martinos Center for Biomedical Imaging, Harvard Medical School — Recent studies with diffusion MRI have shown new aspects of geometric order in the brain, including complex path coherence within the cerebral cortex, and organization of cerebral white matter and connectivity across multiple scales. The main assumption of these studies is that water molecules diffuse along myelin sheaths of neuron axons in the white matter and thus the anisotropy of their diffusion tensor observed by MRI can provide information about the direction of the axons connecting different parts of the brain. We model the diffusion of particles confined in the space of between the bundles of cylindrical obstacles representing fibrous structures of various orientations. We have investigated the directional properties of the diffusion, by studying the angular distribution of the end point of the random walks as a function of their length, to understand the scale over which the distribution randomizes. We will show evidence of qualitative change in the behavior of the diffusion for different volume fractions of obstacles. Comparisons with three-dimensional MRI images will be illustrated.

12:39PM Q41.00008 Adhesion of a Cylindrical Bacterium in the Presence of DLVO Potential, JIAYI SHI, SINAN MUFTU, APRIL GU, KAI-TAK WAN, Northeastern university — A single cigar shape bacterium attaches to a rigid substrate (e.g. sand surface). In the presence of electrostatic double layers and van der Waals attraction according to the Derjaguin-Landau-Verwey-Overbeek (DLVO) theory, the bacterium glycoprotein shell deforms and may settle in either the primary or secondary energy minimum depending on whether it has sufficient energy to overcome the repulsive energy barrier. The adhesion-detachment mechanics is derived using a computational approach, and the followings are obtained: (i) relation between the applied load and contact area with the substrate, (ii) deformed profile at equilibrium, (iii) mechanical stress distribution in the shell, (iv) critical compressive load to force the shell going from secondary energy minimum to primary, and (v) “pull-off” forces to detach the shell from substrate. The model leads to better understanding of bacteria adhesion-aggregation-transportation, and has significant relevance to environmental and medical sciences.

12:51PM Q41.00009 Hydrodynamic behavior of tumor cells in a confined model microvessel, ZEINA S. KHAN, SIVA A. VANAPALLI, Department of Chemical Engineering, Texas Tech University — An important step in cancer metastasis is the hydrodynamic transport of circulating tumor cells (CTCs) through microvasculature. In vivo imaging studies in mice models show episodes of confined motion and trapping of tumor cells at microvessel bifurcations, suggesting that hydrodynamic phenomena are important processes regulating CTC dissemination. Our goal is to use microfluidics to understand the interplay between tumor cell rheology, confinement and fluid forces that may help to identify physical factors determining CTC transport. We use leukemia cells as model CTCs and mimic the in vivo setting by investigating their motion in a confined microchannel with an integrated microfluidic manometer to measure time variations in the excess pressure drop during cell motion. Using image analysis, variations in excess pressure drop, cell shape and cell velocity are simultaneously quantified. We find that the throughput of the technique is high enough (~100 cells/min) to assess tumor cell heterogeneity. Therefore, in addition to measuring the hydrodynamic response of tumor cells in confined channels, our results indicate that the microfluidic manometer device could be used for rapid mechanical phenotyping of tumor cells.

1:03PM Q41.00010 Flow and rupture of vesicles in narrow channels, ALISON HARMAN, MARTIN BERTRAND, BELA JOOS, University of Ottawa, Ontario, Canada — Small lipid bilayer vesicles, also known as liposomes, are used for drug delivery systems in vasculature. Consequently how they deform and when they become unstable and rupture (lose their inner contents) under capillary flow is of great interest. In addition vesicles with a filling fraction of 0.6 can be considered as a simple mechanical model of red blood cells. We use coarse-grained molecular dynamics (CGMD) simulations with explicit solvent to study lipid bilayer vesicles in 3D capillary flow with filling fractions of 1.0 and 0.6. The shapes of the vesicles obtained in these simulations compare well to other experimental and theoretical studies. Using CGMD allows the study of rupture. This is in contrast to the majority of other approaches which model the bilayer as a purely elastic surface and only allow the investigation of deformation. We look at the stress profiles of these vesicles as measured by the area expansion per lipid along the membrane, and determine the location and pressure of rupture for a given confinement ratio (diameter of the vesicle divided by diameter of the channel). We also discuss the subsequent loss of inner fluid content.

1:15PM Q41.00011 Simulations of cardiovascular blood flow accounting for time dependent deformational forces¹, AMANDA PETERS RANGLES, Harvard University, SIMONE MELCHIONNA, JONAS LATT, SAURO SUCCI, Consiglio Nazionale delle Ricerche, EFTHIMIOS KAXIRAS, Harvard University — Cardiovascular disease is currently the leading cause of death in the United States, and early detection is critical. Despite advances in imaging technology, 50% of these deaths occur suddenly and with no prior symptoms. The development and progression of coronary diseases such as atherosclerosis has been linked to prolonged areas of low endothelial shear stress (ESS); however, there is currently no way to measure ESS in vivo. We will present a patient specific fluid simulation that applies the Lattice Boltzmann equation to model the blood flow in the coronary arteries whose geometries are derived from computed tomography angiography data. Using large-scale supercomputers up to 294,912 processors, we can model a full heartbeat at the resolution of the red blood cells. We are investigating the time dependent deformational forces exerted on the arterial flows from the movement of the heart. The change in arterial curvature that occurs over a heartbeat has been shown to have significant impact on flow velocity and macroscopic quantities like shear stress. We will discuss a method for accounting for these resulting forces by casting them into a kinetic formalism via a Gauss-Hermite projection and their impact on ESS while maintaining the static geomtry obtained from CTA data.

1:27PM Q41.00012 Using vortex corelines to analyze the hemodynamics of patient specific cerebral aneurysm models, GREG BYRNE, FERNANDO MUT, JUAN CEBRAL, George Mason University — We construct one-dimensional sets known as vortex corelines for computational fluid dynamic (CFD) simulations of blood flow in patient specific cerebral aneurysm models. These sets identify centers of swirling blood flow that may play an important role in the biological mechanisms causing aneurysm growth, rupture, and thrombosis. We highlight three specific applications in which vortex corelines are used to assess flow complexity and stability in cerebral aneurysms, validate numerical models against PIV-based experimental data, and analyze the effects of flow diverting devices used to treat intracranial aneurysms.

1:39PM Q41.00013 Picoliter droplet-based digital peptide nucleic acid clamp PCR and dielectric sorting for low abundant K-ras mutations, HUIDAN ZHANG, RALPH SPERLING, ASSAF ROTEM, LIANFENG SHAN, JOHN HEYMAN, YIZHE ZHANG, DAVID WEITZ, School of Engineering and Applied Sciences, Department of Physics, Harvard University — Colorectal cancer (CRC) remains the second leading cause of cancer-related mortality in the US, and the 5-year survival of metastatic CRC (mCRC) is less than 10%. Although monoclonal antibodies against epidermal growth factor receptor (EGFR) provide incremental improvements in survival, approximately 40% of mCRC patients with activating KRAS mutations won't benefit from this therapy. Peptide nucleic acid (PNA), a synthetic non-extendable oligonucleotides, can bind strongly to completely complementary wild-type KRAS by Watson-Crick base pairing and suppress its amplification during PCR, while any mutant allele will show unhindered amplification. The method is particularly suitable for the simultaneously detection of several adjoining mutant sites, just as mutations of codons 12 and 13 of KRAS gene where there are totally 12 possible mutation types. In this work, we describe the development and validation of this method, based on the droplet-based digital PCR. Using a microfluidic system, single target DNA molecule is compartmentalized in microdroplets together with PNA specific for wild-type KRAS, thermocycled and the fluorescence of each droplet was detected, followed by sorting and sequencing. It enables the precise determination of all possible mutant KRAS simultaneously, and the precise quantification of a single mutated KRAS in excess background unmutated KRAS.

1:51PM Q41.00014 Liquid solution delivery through the pulled nanopipette combined with QTF-AFM system¹, SANGMIN AN, Seoul Nation University, COREY STAMBAUGH, National Institute of Standards and Technology, GUNN KIM, Sejong University, MANHEE LEE, Harvard University, YONGHEE KIM, KUNYOUNG LEE, WONHO JHE, Seoul Nation University — Nanopipette is a versatile fluidic tool for biochemical analysis, controlled liquid delivery in bio-nanotechnology. However, most of the researches have been performed in solution based system, thus it is challenge to study nanofluidic properties of the liquid solution delivery through the nanopipette in ambient conditions. In this work, we demonstrated the liquid ejection, dispersion, and subsequent deposition of the nanoparticles via a 30 nm aperture pipette based on the quartz tuning fork – atomic force microscope (QTF-AFM) combined nanopipette system.

Session Q42 DBIO GSNP: Focus Session: Stochastic Population Dynamics II - Games and Spatial Dynamics 156C

11:15AM Q42.00001 Bacterial Games, ERWIN FREY, Ludwig-Maximilians-Universitaet Muenchen — Microbial laboratory communities have become model systems for studying the complex interplay between evolutionary selection forces, stochastic fluctuations, and spatial organization. Two fundamental questions that challenge our understanding of evolution and ecology are the origin of cooperation and biodiversity. Both are ubiquitous phenomena yet conspicuously difficult to explain since the fitness of an individual or the whole community depends in an intricate way on a plethora of factors, such as spatial distribution and mobility of individuals, secretion and detection of signaling molecules, toxin secretion leading to inter-strain competition and changes in environmental conditions. We discuss two possible solutions to these questions employing concepts from evolutionary game theory, nonlinear dynamics, and the theory of stochastic processes. Our work provides insights into some minimal requirements for the evolution of cooperation and biodiversity in simple microbial communities. It further makes predictions to be tested by new microbial experiments.

11:51AM Q42.00002 Evolutionary dynamics of range expansions with curved fronts and inflationary directed percolation, MAXIM LAVRENTOVICH, Harvard University, KIRILL KOROLEV, Massachusetts Institute of Technology, DAVID NELSON, Harvard University — We compare the evolutionary dynamics of populations expanding into a new territory with flat and curved fronts. When actively reproducing individuals confined to a thin, uniform population front experience deleterious mutations, the evolutionary dynamics fall into the directed percolation (DP) universality class. At the DP phase transition, the selective advantage of the fit individuals balances the deleterious mutation rate. Curvature in the front changes the dynamics: Sectors of the population become causally disconnected after a time $t_* = R_0/v$, where R_0 is the initial radius of the population and v is the radial front propagation speed. The reproducing population size increases, creating an inflationary effect that prevents the loss of fit individuals due to sector boundary diffusion and sector interactions. We develop a generalization of the Domany-Kinzel model on amorphous, isotropic lattices to simulate radial expansions. We find scaling functions characterizing the effects of inflation at criticality. We also discuss analytic results for two-point correlation functions and survival probabilities in the two limiting cases of no mutations (compact DP) and no selection.

12:03PM Q42.00003 Competition and cooperation in one-dimensional stepping stone models, KIRILL KOROLEV, Massachusetts Institute of Technology, DAVID NELSON, Harvard University — Mutualism and cooperation are major biological forces sustaining ecosystems and enabling complex evolutionary adaptations. Although spatial degrees of freedom and number fluctuations often significantly affect evolutionary dynamics, their effects on mutualism are not fully understood. We show that, even when mutualism confers a distinct selective advantage, it persists only in populations with high density and frequent migrations. When these parameters are reduced, number fluctuations lead to the local extinctions of one of the species, segregating the species in space and decreasing the size of regions where cooperation occurs. The segregated and mutualistic states are separated by a second order nonequilibrium phase transition. Generically, this transition is in the universality class of directed percolation (DP), but the phase diagram is strongly influenced by an exceptional symmetric directed percolation (DP2) transition. This influence is manifested in a strong increase in the resilience to number fluctuations of symmetric mutualism, when organisms benefit equally from interacting.

12:15PM Q42.00004 Range expansion of mutualists, MELANIE J.I. MULLER, Harvard University, KIRILL S. KOROLEV, Massachusetts Institute of Technology, ANDREW W. MURRAY, DAVID R. NELSON, Harvard University — The expansion of a species into new territory is often strongly influenced by the presence of other species. This effect is particularly striking for the case of mutualistic species that enhance each other's proliferation. Examples range from major events in evolutionary history, such as the spread and diversification of flowering plants due to their mutualism with pollen-dispersing insects, to modern examples like the surface colonisation of multi-species microbial biofilms. Here, we investigate the spread of cross-feeding strains of the budding yeast *Saccharomyces cerevisiae* on an agar surface as a model system for expanding mutualists. Depending on the degree of mutualism, the two strains form distinctive spatial patterns during their range expansion. This change in spatial patterns can be understood as a phase transition within a stepping stone model generalized to two mutualistic species.

12:27PM Q42.00005 Cooperation, cheating, and collapse in microbial populations , JEFF GORE, Massachusetts Institute of Technology — Natural populations can suffer catastrophic collapse in response to small changes in environmental conditions, and recovery after such a collapse can be exceedingly difficult. We have used laboratory yeast populations to study proposed early warning signals of impending extinction. Yeast cooperatively breakdown the sugar sucrose, meaning that there is a minimum number of cells required to sustain the population. We have demonstrated experimentally that the fluctuations in the population size increase in magnitude and become slower as the population approaches collapse. The cooperative nature of yeast growth on sucrose suggests that the population may be susceptible to cheater cells, which do not contribute to the public good and instead merely take advantage of the cooperative cells. We have confirmed this possibility experimentally by using a cheater yeast strain that lacks the gene encoding the cooperative behavior [1]. However, recent results in the lab demonstrate that the presence of a bacterial competitor may drive cooperation within the yeast population.

1:03PM Q42.00006 ABSTRACT WITHDRAWN —

1:15PM Q42.00007 Evolution of cooperation in microbial biofilms - A stochastic model for the growth and survival of bacterial mats , JOHANNES KNEBEL, JONAS CREMER, ANNA MELBINGER, ERWIN FREY, Ludwig-Maximilians University of Munich — Cooperative behavior is essential for microbial biofilms. The structure and composition of a biofilm change over time and thereby influence the evolution of cooperation within the system. In turn, the level of cooperation affects the growth dynamics of the biofilm. Here, we investigate this coupling for an experimentally well-defined situation in which mutants of the *Pseudomonas fluorescens* strain form a mat at the liquid-air interface by the production of an extra-cellular matrix [1]. We model the occurrence of cooperation in this bacterial population by taking into account the formation of the mat. The presence of cooperators enhances the growth of the mat, but at the same time cheaters can infiltrate the population and put the viability of the mat at risk. We find that the survival time of the mat crucially depends on its initial dynamics which is subject to demographic fluctuations [2]. More generally, our work provides conceptual insights into the requirements and mechanisms for the evolution of cooperation.

1:27PM Q42.00008 Bacterial Cheating Limits the Evolution of Antibiotic Resistance¹ , EUGENE YURTSEV, HUI XIAO CHAO, Department of Physics, Massachusetts Institute of Technology, MANOSHI DATTA, Computational and Systems Biology, Massachusetts Institute of Technology, TATIANA ARTEMOVA, JEFF GORE, Department of Physics, Massachusetts Institute of Technology — The emergence of antibiotic resistance in bacteria is a significant health concern. Bacteria can gain resistance to the antibiotic ampicillin by acquiring a plasmid carrying the gene beta-lactamase, which inactivates the antibiotic. This inactivation may represent a cooperative behavior, as the entire bacterial population benefits from removal of the antibiotic. The presence of a cooperative mechanism of resistance suggests that a cheater strain - which does not contribute to breaking down the antibiotic - may be able to take advantage of resistant cells. We find experimentally that a "sensitive" bacterial strain lacking the plasmid conferring resistance can invade a population of resistant bacteria, even in antibiotic concentrations that should kill the sensitive strain. We use a simple model in conjunction with difference equations to explain the observed population dynamics as a function of cell density and antibiotic concentration. Our experimental difference equations resemble the logistic map, raising the possibility of oscillations or even chaotic dynamics.

1:39PM Q42.00009 Does fast migration imply well-mixing? , MICHAEL KHASIN, University of Michigan, EVGENIY KHAIN, Oakland University, LEONARD SANDER, University of Michigan — A popular assumption in population dynamics is that the population is well mixed, i.e., a spatial character of the interactions between the individuals can be neglected. A common justification of this assumption is that the rate of migration between the local possibly well-mixed population-dynamics domains is much larger than the rates of interactions within a domain. We consider a system of local well-mixed domains of varying carrying capacity. In the limit of infinite migration rate we calculate the stationary probability distribution of the total population and find that generally it is not equivalent to the stationary probability distribution of a single well-mixed domain with a large carrying capacity. This proves that fast migration does not generally justify the well-mixed population assumption.

1:51PM Q42.00010 Turing patterns and a stochastic individual-based model for predator-prey systems , SEIDO NAGANO, Ritsumeikan University — Reaction-diffusion theory has played a very important role in the study of pattern formations in biology. However, a group of individuals is described by a single state variable representing population density in reaction-diffusion models and interaction between individuals can be included only phenomenologically. Recently, we have seamlessly combined individual-based models with elements of reaction-diffusion theory. To include animal migration in the scheme, we have adopted a relationship between the diffusion and the random numbers generated according to a two-dimensional bivariate normal distribution. Thus, we have observed the transition of population patterns from an extinction mode, a stable mode, or an oscillatory mode to the chaotic mode as the population growth rate increases. We show our phase diagram of predator-prey systems and discuss the microscopic mechanism for the stable lattice formation in detail.

Wednesday, February 29, 2012 11:15AM - 2:15PM —

Session Q43 DBIO: Invited Session: Techniques to Study Dynamic Cellular Processes One Molecule at a Time (Including Delbruck Award Lecture) 157AB

11:15AM Q43.00001 Max Delbruck Prize in Biological Physics Lecture: Single-molecule protein folding and transition paths¹ , WILLIAM EATON, Laboratory of Chemical Physics, NIDDK, National Institutes of Health, Bethesda, MD — The transition path is the tiny fraction of an equilibrium molecular trajectory when a transition occurs by crossing the free energy barrier between two states. It is a uniquely single-molecule property, and has not yet been observed experimentally for any system in the condensed phase. The importance of the transition path in protein folding is that it contains all of the mechanistic information on how a protein folds. As a major step toward observing transition paths, we have determined the average transition-path time for a fast and a slow-folding protein from a photon-by-photon analysis of fluorescence trajectories in single-molecule FRET experiments. While the folding rate coefficients differ by 10,000-fold, surprisingly, the transition-path times differ by less than 5-fold, showing that a successful barrier crossing event takes almost the same time for a fast- and a slow-folding protein, i.e. almost the same time to fold when it actually happens.

11:51AM Q43.00002 ATP-induced helicase slippage reveals highly coordinated subunits, MICHELLE D. WANG, Cornell University — Helicases are vital enzymes that carry out strand separation of duplex nucleic acids during replication, repair and recombination. T7 helicase, a model hexameric motor, has been observed to use dTTP, but not ATP, to unwind dsDNA as it translocates along ssDNA. Whether and how different subunits of the helicase coordinate their chemo-mechanical activities and DNA binding during translocation is still under debate. Here we address this question using a single-molecule approach to monitor helicase unwinding. We found that T7 helicase does in fact unwind dsDNA in the presence of ATP and that the unwinding rate is even faster than that with dTTP. However, unwinding was repeatedly interrupted by sudden slippage events, ultimately preventing unwinding over a substantial distance. This behaviour was greatly reduced with the supplement of a small amount of dTTP. These findings presented an opportunity to use nucleotide mixtures to investigate helicase subunit coordination. Our results support a model where nearly all subunits coordinate their chemo-mechanical activities and DNA binding. Such subunit coordination may be general to many ring-shaped helicases and reveals a potential mechanism for regulation of DNA unwinding during replication.

12:27PM Q43.00003 Unraveling the motion of single-stranded DNA binding proteins on DNA using force and fluorescence spectroscopy, TAEKJIP HA, Department of Physics, University of Illinois at Urbana-Champaign — Single-stranded DNA binding (SSB) proteins bind to and control the accessibility of single stranded (ss) DNA generated as a transient intermediate during a variety of cellular processes. For subsequent DNA processing, however, such a tightly wrapped, high-affinity protein-DNA complex still needs to be removed or repositioned quickly for unhindered action of other proteins. Here we show, using single-molecule two- and three-colour fluorescence resonance energy transfer, that SSB can spontaneously migrate along ssDNA. Diffusional migration of SSB helps in the local displacement of SSB by an elongating RecA filament. SSB diffusion also melts short DNA hairpins transiently and stimulates RecA filament elongation on DNA with secondary structure. This observation of diffusional movement of a protein on ssDNA introduces a new model for how an SSB protein can be redistributed, while remaining tightly bound to ssDNA during recombination and repair processes. In addition, using an optomechanical tool combining single-molecule fluorescence and force methods, we probed how proteins with such a large binding site size (~ 65 nucleotides) can migrate rapidly on DNA and how protein-protein interactions and tension may modulate the motion. We observed force-induced progressive unravelling of ssDNA from the SSB surface between 1 and 6 pN, followed by SSB dissociation at ~ 10 pN, and obtained experimental evidence of a reptation mechanism for protein movement along DNA wherein a protein slides via DNA bulge formation and propagation. SSB diffusion persists even when bound with RecO, and at forces under which the fully wrapped state is perturbed, suggesting that even in crowded cellular conditions SSB can act as a sliding platform to recruit and carry its interacting proteins for use in DNA replication, recombination and repair.

1:03PM Q43.00004 Beholding the subcellular world in your PALM: nanometer resolution optical measurements of protein assemblies in cells¹, HARI SHROFF, National Institute of Biomedical Imaging and Bioengineering — Key to understanding a protein's biological function is the accurate determination of its spatial distribution inside a cell. Although fluorescent protein markers enable specific targeting with molecular precision, much of this utility is lost when the resultant fusions are imaged with conventional, diffraction-limited optics. In response, several imaging modalities that rely on the stochastic activation and bleaching of single molecules, and that are capable of resolution $10\times$ below the diffraction limit (250 nm for visible wavelengths), have emerged. This talk will cover superresolution imaging of biological structures using photoactivated localization microscopy (PALM). In addition to covering the theory, we will also discuss the use of the technique in understanding biological phenomena on the nanoscale, including the organization of bacterial chemoreceptors, the movement of actin in neuronal spines, and the stratification of focal adhesions.

1:39PM Q43.00005 Single-molecule conductance measurements of biomolecule translocation across biomimetic nuclear pores¹, CEES DEKKER, Delft University of Technology — After a brief overview of our recent work on solid-state nanopores, I will present single-molecule transport data across biomimetic nanopores that contain the key regulating parts of the nuclear pore complex (NPC). The mechanism for the remarkable selectivity of NPCs has remained unclear in a large part due to difficulties in designing experiments that can probe the transport at the relevant length and time scales. Building and measuring on biomimetic NPCs provides new opportunities to address this long-standing problem. covalently tether the natively unfolded Phe-Gly rich domains (FG-domains) of human nuclear binding proteins to a solid-state nanopore (a 10-100 nm sized hole in a SiN membrane). Ionic current measurements provide a probe to monitor single molecules that traverse the pore. Translocation events are observed for transport receptors (Imp β), whereas transport of passive molecules (BSA) is found to be blocked. Interestingly, a single type of nuclear pore proteins appears already sufficient to form a selective barrier for transport. A translocation time of about 2.5 ms is measured for Imp β . This time is found to be similar for transport across Nup153 and Nup98 coated pores, although the observed ionic conductance differs between these two types of pores. We compare two simple models for the pore conductance and find, for both Nups, that the data fits best to a model with an open central channel and a condensed layer along the outer circumference of the pore. reproducing the key features of the NPC, our biomimetic approach opens the way to study a wide variety of nucleo-cytoplasmic transport processes at the single-molecule level in vitro.

Session Q44 DPOLY: Focus Session: Interparticle Interactions in Polymer Nanocomposites - Transport and Dynamics 157C

11:15AM Q44.00001 Multiscale structure, interfacial cohesion, adsorbed layers, miscibility and properties in dense polymer-particle mixtures, KEN SCHWEIZER, University of Illinois at Urbana-Champaign — A major goal in polymer nanocomposite research is to understand and predict how the chemical and physical nature of individual polymers and nanoparticles, and thermodynamic state (temperature, composition, solvent dilution, filler loading), determine bulk assembly, miscibility and properties. Microscopic PRISM theory provides a route to this goal for equilibrium disordered mixtures. A major prediction is that by manipulating the net polymer-particle interfacial attraction, miscibility is realizable via the formation of thin thermodynamically stable adsorbed layers, which, however, are destroyed by entropic depletion and bridging attraction effects if interface cohesion is too weak or strong, respectively. This and related issues are quantitatively explored for miscible mixtures of hydrocarbon polymers, silica nanospheres, and solvent using x-ray scattering, neutron scattering and rheology. Under melt conditions, quantitative agreement between theory and silica scattering experiments is achieved under both steric stabilization and weak depletion conditions. Using contrast matching neutron scattering to characterize the collective structure factors of polymers, particles and their interface, the existence and size of adsorbed polymer layers, and their consequences on microstructure, is determined. Failure of the incompressible RPA, accuracy of PRISM theory, the nm thickness of adsorbed layers, and qualitative sensitivity of the bulk modulus to interfacial cohesion and particle size are demonstrated for concentrated PEO-silica-ethanol nanocomposites. Temperature-dependent complexity is discovered when water is the solvent, and nonequilibrium effects emerge for adsorbing entangled polymers that strongly impact structure. By varying polymer chemistry, the effect of polymer-particle attraction on the intrinsic viscosity is explored with striking non-classical effects observed. This work was performed in collaboration with S.Y.Kim, L.M.Hall, C.Zukoski and B.Anderson.

11:51AM Q44.00002 Organically Modified Nanoclay-Reinforced Rigid Polyurethane Films, YONG TAE PARK, Department of Chemical Engineering and Materials Science, University of Minnesota, YUQIANG QIAN, Department of Chemistry, University of Minnesota, CHRIS LINDSAY, Huntsman Polyurethanes, ANDREAS STEIN, Department of Chemistry, University of Minnesota, CHRISTOPHER MACOSKO, Department of Chemical Engineering and Materials Science, University of Minnesota — The nanodispersion of vermiculite in polyurethanes was investigated to produce organoclay-reinforced rigid gas barrier films. Reducing gas transport can improve the insulation performance of closed cell polyurethane foam. In a previous study, the dispersion of vermiculite in polyurethanes without organic modification was not sufficient due to the non-uniform dispersion morphology. When vermiculite was modified by cation exchange with long-chain quaternary ammonium cations, the dispersion in methylene diphenyl diisocyanate (MDI) was significantly improved. Dispersion was improved by combining high intensity dispersive mixing with efficient distributive mixing. Polymerization conditions were also optimized in order to provide a high state of nanodispersion in the polyurethane nanocomposite. The dispersions were characterized using rheological, microscopic and scattering/diffraction techniques. The final nanocomposites showed enhancement of mechanical properties and reduction in permeability to carbon dioxide at low clay concentration (around 2 wt percent).

12:03PM Q44.00003 Shear viscosity of polymer nanocomposites from NEMD simulations, JAGANNATHAN T. KALATHI, SANAT K. KUMAR, Columbia University, GARY S. GREST, Sandia National Laboratories — Polymer nanocomposites (PNC) are preferred for a variety of applications since they offer excellent thermal, electrical, and mechanical properties. The viscosity of PNC is primarily a strong function of filler size. For micron-sized fillers, the shear viscosity increases with filler volume fraction following the well-known Einstein relationship. However as the particle size approaches the nanoscale, the viscosity is found to either increase or decrease depending on the strength of interactions between the particle and polymer. In this study, the shear viscosity of an entangled polymer melt of $N=400$ beads of diameter σ with and without fillers is estimated using NEMD simulations. The diameter of the nanoparticles ($1-10\sigma$) and volume fraction ($0.05-0.3$) are varied for shear rate from 10^{-2} to $10^{-6}\tau^{-1}$. The viscosity of PNC decreases when compared to pure melt for nanoparticles of size 1σ and recovers to the value of a pure melt when the size approaches 10σ , provided all the interactions are neutral. It thus appears that the increase in viscosity embodied in the Einstein relationship only manifests itself for large nanoparticle size $>10\sigma$.

12:15PM Q44.00004 Towards the Next Generation of Polymer Nanocomposites: More Rigid, Lighter Weight, Yet Easier to Process¹, JEONGJAE WIE, JONATHAN SEPPALA, MICHAEL MACKAY, University of Delaware, WOO JIN CHUNG, JEFFREY PYUN, University of Arizona — Polymer nanocomposites are attractive for their lightness in weight and excellent mechanical reinforcement. Current nanocomposites incorporate high aspect ratio fillers such as clays, carbon nanotubes (CNT), and graphenes. Exfoliation of clay, for example, is essential to obtain maximum mechanical reinforcement, yet this results in a 2 to 4 order of magnitude melt viscosity increase. This high viscosity leads to a reduction in the production rate and/or increased processing cost, which is undesirable. In order to obtain reduced melt viscosity without sacrificing the advantages of current nanocomposites, we prepared poly(styrene) (PS) nanocomposites by inclusion of various spherical nanoparticles using a technique that ensures good dispersion. Tensile tests demonstrated enhanced tensile modulus in the glassy state while a reduced melt viscosity was observed. The results show that nanoparticle geometry is extremely important and nanoscale effects can lead to the next generation of polymer nanocomposites.

12:27PM Q44.00005 A Comparative Study of Interfacial Slip in Polymer Blends with Nanoparticles and Diblock Copolymer Compatibilizers, JOSEPH ORTIZ, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University — The interfacial region in polymer blends has been identified as a low viscosity region in which considerable slip can occur when the blend is subjected to shear forces. Here we use Molecular Dynamics simulations to establish and compare the roles that added nanoparticle fillers and diblock copolymers play in modifying the interfacial rheology. By choosing conditions under which the fillers and diblocks are localized, either in the two phases or at the interface, we can look at the interplay between their strengthening capabilities and the change in the interfacial slip behavior. We examine particle size, attraction between the particle and the polymer component, and the amount of filler in the material and compared this to systems including diblock copolymers at the same volume fraction. Our studies are performed, for a variety of shear values, both above and below the point at which the filler particles form a transient network in the blend.

12:39PM Q44.00006 The Effect of Elongational Flow on the Placement and Orientation of Nanorods in Polymer: Modeling and Experiments, JAY PARK, Cornell University, VIBHA KALRA, Drexel University, YONG JOO, Cornell University — Nanorods are often incorporated into a polymer to enhance its functionality. Gaining control over the placement of nanorods in polymer is important to improve the desired nanocomposite material property and for application like solar cell. First, we used coarse-grained molecular dynamics (CGMD) simulation to quantitatively examine the effect of elongational flow on the placement of model nanorods in homopolymer matrix. We have investigated how flow strength, concentration, interaction, and aspect ratio of nanorods affect its placement in homopolymer. As an analogous experiment, we have electrospun polyvinyl alcohol (PVA) in water with Au nanorods. The experimental result showed dispersion and alignment of Au nanorods, as predicted by the simulation. We also demonstrated selective placement of nanorods along the outer layer of fiber by co-axially electrospinning PVA/Au nanorods and pure PVA as shell and core, respectively. The material properties of the PVA/Au nanocomposite fiber are tested to show its potential application such as electromagnetic interference (EMI) shielding. The good agreements between simulation and experiment suggest that CGMD simulation can be used as a predictive tool for controlling nanorod placement in a polymer under extensional flow.

12:51PM Q44.00007 Directed Self-Assembly of Nanoparticles via Flexible-Blade Flow Coating¹, DONG YUN LEE, JONATHAN PHAM, JIMMY LAWRENCE, CHEOL HEE LEE, HYUN SUK KIM, CASSANDRA PARKOS, TODD EMRICK, ALFRED J. CROSBY, University of Massachusetts Amherst — We present a facile, non-lithographic, one-step method termed flexible-blade flow coating to direct the assembly of quantum dots. This versatile technique exploits the phenomenon known as the “coffee ring effect” coupled with confined convective flow and controlled stick-slip motion to fabricate ribbons and fabrics with a broad range of length scales of nearly any material. We achieve nanostripe dimensions of width below 300 nm, thickness of a single nanoparticle (~ 8 nm), and continuous length exceeding 5 cm. This multi-length scale control is facilitated by the use of a flexible blade, which allows capillary forces to self-regulate the uniformity of convective flow processes. We exploit solvent mixture dynamics and nanoparticle chemistry to enhance intra-assembly particle packing, leading to novel assembly properties including conductivity and free-standing mechanical flexibility and strength. This simple technique and the use of novel materials open up a new paradigm for integration of nanoscale patterns over large areas for various applications.

1:03PM Q44.00008 Properties of Macroscopic Nanoparticle Assemblies Fabricated by Flexible Blade Flow Coating, JONATHAN T. PHAM, DONG YUN LEE, JIMMY LAWRENCE, CHEOL HEE LEE, TODD EMRICK, ALFRED J. CROSBY, University of Massachusetts Amherst — Nanoparticle assemblies have gained much interest for their potential in electronic, photonic, optical, chemical, and biological applications. Although one of the greatest challenges is the controlled positioning of nanoscale components into the desired multi-length scale structures, understanding the properties of nanoparticle assemblies has also remained elusive. We have developed a technique termed flexible blade flow coating to direct the assembly of nanoparticles into ribbons and fabrics with a broad range of length scales. Ribbons and fabrics constructed with photoreactive quantum dots are crosslinked by UV irradiation affording long, flexible and robust structures that allow for subsequent liftoff from the substrate by dissolution of a sacrificial underlayer. The structural integrity of freely floating fabrics and extremely high aspect ratio ribbons are observed through fluorescence microscopy. Physical properties of these assemblies are explored with varying dimensions and ligand chemistry. We find that nanoparticle ribbons and fabrics possess unique properties in comparison to continuous polymer thin films, such as spherical wrapping and two-dimensional flexibility.

1:15PM Q44.00009 Reversible Shear-Flow-Induced Polymer and Colloid Aggregates, HSIEH CHEN, ALFREDO ALEXANDER-KATZ, MIT — Using hydrodynamic simulations and a coarse-grained interaction model, we show that self-associating polymer and colloid mixtures can form reversible flow-induced aggregates in shear flow. We find that when increasing shear rates, the mixtures go through four distinct conformations from no aggregation to dense aggregates. The different conformations are verified by analyzing their radial distribution functions, $g(r)$, as well as by visual inspection. Furthermore, we find that the formation of the aggregates is reversible. That is, the shear-induced aggregates disappear when we decrease the shear rates, and reappear when we increase the shear rates again.

1:27PM Q44.00010 Impact of Carbon Nanoparticle Shape on Polymer Dynamics in Nanocomposites¹, BRAD MILLER, MARK DADMUN, Department of Chemistry, University of Tennessee, Knoxville — In forming quality nanocomposites of carbon-based nanoparticles (CNPs) in a polymer matrix, achieving and maintaining a high degree of dispersion is a crucial problem. One method to attain well-dispersed CNP nanocomposites is to incorporate non-covalent interactions between the CNP and matrix, which also impacts the dynamics of the polymer chain. In this work, T2 NMR relaxometry (T2 NMR) examines the effect on polymer chain dynamics of incorporating CNPs into polystyrene-co-acrylonitrile (SAN) random copolymer matrices. In SAN-CNP composites, the segmental-chain dynamics can be influenced by the non-covalent interactions formed with the nanoparticle (interacting), but are also influenced by the CNP steric bulk alone (non-interacting). The use of T2 NMR allows for the examination of the influence of the extent of non-covalent interactions on this segmental chain level. This segmental level view also allows for the distinction between relaxation dynamics of the interacting and non-interacting regimes. Current data indicates that increased acrylonitrile content in the copolymer results in increased non-covalent interactions and overall slowing of chain dynamics.

1:39PM Q44.00011 Modifying Fragility and Length Scales of Polymer Glass Formation with Nanoparticles, BEATRIZ A. PAZMINO, Physics Dept., Wesleyan University, Middletown, CT, JACK F. DOUGLAS, Polymer Division, NIST, Gaithersburg, MD, FRANCIS W. STARR, Physics Dept., Wesleyan University, Middletown, CT — We investigate the effects of nanoparticles on glass formation in a model polymer melt by molecular dynamics simulations. The addition of nanoparticles allows us to change the glass transition temperature T_g , the fragility of glass formation, and both static and dynamical length scales in a controlled fashion. We contrast the length scales of static density changes with the length scale over which nanoparticles perturb the dynamics, as well as the length scale of cooperative string-like motion. Using the Adam-Gibbs approach, we show how the changes of fragility can be interpreted as a measure of the scale of cooperative string-like motion. We contrast the behavior along isobaric and isochoric paths to T_g , and find that changes along an isobaric path (most relevant experimentally) are much smaller than those along an isochoric path.

1:51PM Q44.00012 Glass transition temperature of polymer nano-composites with polymer and filler interactions, KATSUMI HAGITA, National Defense Academy, HIROSHI TAKANO, KEIO University, MASAO DOI, University of Tokyo, HIROSHI MORITA, AIST — We systematically studied versatile coarse-grained model (bead spring model) to describe filled polymer nano-composites for coarse-grained (Kremer-Grest model) molecular dynamics simulations. This model consists of long polymers, crosslink, and fillers. We used the hollow structure as the filler to describe rigid spherical fillers with small computing costs. Our filler model consists of surface particles of icosahedra fullerene structure C320 and a repulsive force from the center of the filler is applied to the surface particles in order to make a sphere and rigid. The filler's diameter is 12 times of beads of the polymers. As the first test of our model, we study temperature dependence of volumes of periodic boundary conditions under constant pressures through NPT constant Andersen algorithm. It is found that Glass transition temperature (T_g) decrease with increasing filler's volume fraction for the case of repulsive interaction between polymer and fillers and T_g weakly increase for attractive interaction.

2:03PM Q44.00013 Payne effect in model nanocomposite the role of polymer confinement, HELENE MONTES, FRANÇOIS LEQUEUX, ESPCI-Paristech, PAPON AURELIE TEAM — Payne effect is a non-linearity observed in polymer nanocomposites at small strain amplitudes, above the bulk glass transition temperature. The origin is the non-linear mechanical response of the polymer located near the solid fillers. However the exact nature of the mechanical response is still the object of debate. We have developed since ten years model nano-composite systems consisting in monodisperse spherical particles dispersed in an elastomer matrix. Thanks to NMR and Neutrons scattering, we have been able to determine precisely the amount of polymer confined between pairs of particles and with a modified dynamics. From that we have deduced that the Payne effect clearly originates in two mechanisms: i) around each particle, a glass transition temperature gradient ii) around this first layer, a modified topology of the polymer —originating itself in the glassiness of the polymer very near the particles. Hence, we are able to build a master curve for the Payne effect amplitude versus the number of particles connected to their neighbors by these two layers, that gathers measurements at various temperatures, volume fractions and frequencies.

Session Q45 DPOLY: Elastomers and Gels 159**

11:15AM Q45.00001 Can a Rheological Experiment Distinguish Between a Gel and a Soft Glass? If yes, which Experiment?, HORST WINTER, University of Massachusetts Amherst — Generic rheological differences between gels and soft glasses appear most pronounced in the *immediate approach of the liquid-to-solid transition from the liquid side*. Two model systems of known linear viscoelasticity were chosen to exemplify the two material classes: a crosslinking PDMS represents gelation and a concentrated, aqueous suspension represents the soft glass transition. The longest relaxation time and the zero shear viscosity diverge for both materials, which look very similar in this way. However, the relaxation time spectrum and its expression as complex modulus, with components G' and G'' , provide a clear distinction between gelation and the soft glass transition. While the long-time component of the relaxation time spectrum follows a powerlaw in time for both, $\log H \sim n \log t$, their powerlaw exponent n is of different sign: negative n for the critical gel (material at the gel point) (Chambon et al. Polym Bull 13:499–503, 1985; Winter et al. J Rheology 30:367–382, 1986; Chambon et al. J Rheol 31:683–697, 1987) and positive n for the soft glass (Siebenbürger et al. J Rheology 53:707–720, 2009; Winter et al. Rheol Acta 48:747–753). The powerlaw spectrum is cut off by the diverging, longest relaxation time (called “alpha relaxation time” for the soft glass) in the approach of the liquid-to-solid transition. In summary, relaxation data provide a clear distinction between these two classes of materials.

11:27AM Q45.00002 Effects of crosslinker concentration and chemical disorder on the nonlinear mechanics of thermoreversibly associating networks, GLENN H. FREDRICKSON, University of California, Santa Barbara, ROBERT S. HOY, Yale University — We present simulation studies of thermoreversibly associating polymer networks that relate dramatic differences in nonlinear mechanics (e. g. creep and fracture) to differences in crosslinker placement and consequent differences in the equilibrium structure and quiescent dynamics of these systems. Our results illustrate how the greater structural and dynamical heterogeneity in systems possessing randomly placed crosslinkers leads to higher mobility, increased creep compliance and decreased fracture toughness in comparison to systems with uniformly spaced crosslinkers. Further quiescent-dynamical slowdown and mechanical property enhancement may be obtained through well-defined but nonuniform placement of crosslinkers. The variation of properties with crosslinker concentration c and parent chain length N is also investigated. Increasing characteristic chemical distances between crosslinkers decreases effects arising from network “loops,” the prevalence of which is closely associated with chemical order. At fixed c , while differences associated with chemical (dis)order decrease with increasing N , they remain dramatic in the $N \sim N_e$ regime which is often used in practical applications.

11:39AM Q45.00003 Mechanically induced oscillations in Belousov-Zhabotinsky gels, IRENE CHEN, Massachusetts Institute of Technology, OLGA KUKSENOK, VICTOR YASHIN, ANNA BALAZS, University of Pittsburgh, KRISTYN VAN VLIET, Massachusetts Institute of Technology — Belousov-Zhabotinsky (BZ) gels are a unique class of stimuli-responsive materials that exhibit periodic changes in both color and size due to the self-oscillating kinetics of the BZ reduction-oxidation reaction. Such oscillations last for several hours, ending when a steady-state is reached in which the chemical reactants have been depleted. Here, we demonstrate that a depleted, non-oscillating BZ gel can be mechanically resuscitated, extending the oscillatory functionality of the material. These results represent the first experimental demonstration of mechanically induced oscillations in N-isopropylacrylamide-Ru(bpy)₃ gels. We characterize this phenomenon by quantifying the critical stress required to trigger oscillations, and the dependence of period and amplitude for triggered oscillations as a function of malonic acid concentration. Lastly, we demonstrate sensor applications comprising arrays of discrete BZ gel discs in which individual gels oscillate in color upon compression and have the capacity to transmit chemical signals away from the deformation site.

11:51AM Q45.00004 Nonlinear Elasticity of Entangled Polymer Networks, OZAN SARIYER, University of North Carolina at Chapel Hill, SERGEY PANYUKOV, P. N. Lebedev Physics Institute, Russian Academy of Sciences, MICHAEL RUBINSTEIN, University of North Carolina at Chapel Hill — We develop a microscopic model for elasticity of entangled polymer networks. The classical models of rubber elasticity (affine network and phantom network models) take into account only the effect of cross-links, but not the entanglements between polymer chains. For uniaxial deformation, the entanglement effects can be characterized by the dependence of Mooney ratio on network deformation. Constrained network models (such as constrained-junction and diffused-constraint models), tube models (such as Edwards' tube and nonaffine tube models) as well as phenomenological models (such as Mooney-Rivlin model) have been proposed to capture the experimentally observed dependence of Mooney ratio on network deformation. One of the latest efforts in the field is the slip-tube model, in which the entanglements are represented by slip-rings that can glide along the network chains but elastically constrained in space. The model we study improves over the original slip-tube model by taking into account harmonic interactions along the chain between such slip-links. We analytically and numerically solve the new microscopic model and present our results in comparisons with experimental and simulation data for both uniaxial and biaxial deformation.

12:03PM Q45.00005 Coarse grain modeling of the high-rate stress-strain behavior for select model Poly[urethane urea] (PUU) elastomers, T.L. CHANTAWANSRI, Y.R. SLOZBERG, A. HSIEH, J.W. ANDZELM, Army Research Laboratory — Microphase-separated PUU, which consists of 4,4'-dicyclohexylmethane diisocyanate, diethyltoluenediamine and poly[tetramethylene oxide](PTMO), exhibits versatile mechanical properties making them an excellent choice for potential applications in the form of films, adhesives, coatings and matrix materials for composites. To elucidate the effects of composition, including the hard segment content & molecular weight of PTMO, on rate-dependent mechanical deformation in the high strain-rate regime ($>> 10^5/s$) the stress-strain behavior for PUU at various rates are calculated for four model systems using a coarse-grain model. Pair interactions between topologically non-connected particles are described by the standard truncated Lennard-Jones (LJ) pair potential, where bonded particles interact according to the standard FENE/LJ potential. An angle harmonic potential is also used to enforce the rigidity of the hard segments, and the system is evolved using molecular dynamics. Stress-strain curves are calculated at various strain-rates and qualitatively agree with experimental results when extrapolated to higher rate. Further analysis of the morphology is also performed to characterize the morphology and discern its connection to the calculated mechanical properties.

12:15PM Q45.00006 Swelling Behavior of Crosslinked Rubber: Does the Peak in Dilational Modulus Exist?¹, BEN XU, XIAOJUN DI, GREGORY B. MCKENNA, Department of Chemical Engineering, Texas Tech University — Previous work² has shown that when handled properly, Frenkel³-Flory-Rehner⁴(FFR) theory is an excellent model to explain swelling behavior with the exception of failing to describe the peak of the swelling activity parameter S , or dilational modulus. This peak was first observed by Gee et al.⁵ and has eluded explanations. In the present work, we explored the importance of fitting procedure to the isopiestic data on the presence of the peak of S . We found the peak in S disappears when using a FFR model based fit instead of the empirical or polynomial fits used previously. We take model material parameters and show that adding less than 1% random error to the theoretical curves can lead to the peak in S . Our findings suggest strongly that the “peak” in S is due to experimental errors that are amplified by the fitting method.

12:27PM Q45.00007 Microphase Separation and Dynamics of Elastomeric Polyureas¹, JAMES RUNT, ALICIA CASTAGNA, TAEYI CHOI, YOUMI JEONG, Penn State University — Polyureas, consisting of alternating polyether soft segments and urea-containing hard segments, are of interest for shock and other energy absorbing applications. The properties of these materials are strongly influenced by microphase separation of the hard and soft segments, which is rather incomplete. Bulk- and solution-polymerized polyureas based on oligomeric polytetramethylene oxide and methylene diphenyl diisocyanate were investigated, and the role of PTMO molecular weight was identified. The morphology was characterized using atomic force microscopy and quantitative degrees of phase separation were determined from small-angle X-ray scattering. Dielectric relaxation spectroscopy and dynamic mechanical analysis were used to probe the dynamics. Particular attention was paid to the segmental dynamics of the soft phase, which has been proposed to be a major contributor to shock energy absorption in these materials.

¹Supported by the Office of Naval Research.

12:39PM Q45.00008 Opening and Closing of Nanocavities under Stress in Soft Nanocomposites: A Real Time Small Angle X-ray Scattering (SAXS) Observation, HUAN ZHANG, JORDAN DE CREVOISIER, Soft Matter Science and Engineering, ESPCIParisTech-CNRS-UPMC, Paris, France, ARTHUR SCHOLZ, Materials Research Laboratory, UCSB, 93106-5121 CA, U.S.A., FABIEN VION-LOISEL, Michelin, EDWARD J. KRAMER, Departments of Materials and Chemical Engineering, UCSB, 93106-5050, COSTANTINO CRETON, Soft Matter Science and Engineering, ESPCIParisTech-CNRS-UPMC, Paris, France — Cavitation occurring at the nanometer length scale has been recently demonstrated conclusively in rubbers¹. Real time SAXS with synchrotron radiation is employed to probe the structure changes in carbon black filled styrene-butadiene rubber (SBR) under uniaxial tension. The scattering invariant $Q(\lambda)$, where λ is the extension ratio, increases sharply, which we attribute to void formation, above a critical true stress (~ 25 MPa) that is roughly independent of both filler content and crosslinking density. During step-cycle tests Q decreases on unloading to Q_0 , its value before any testing, and does not increase again until λ exceeds the maximum previous $\lambda = \lambda_{max}$, showing that the voids close upon unloading and only reappear upon reloading when $\lambda > \lambda_{max}$ (Mullins effect). We attribute the increase of the scattering invariant once λ exceeds λ_{max} to the creation of new voids rather than to the reopening of old ones. The scattering of the voids in the region $q < 0.1 \text{ nm}^{-1}$ can be separated from that of the carbon black particles and provides information on average void size and shape.

12:51PM Q45.00009 Reversible shape memory, SERGEI SHEIKO, JING ZHOU, SARAH WHITE, VALERIE ASHBY, University of North Carolina at Chapel Hill — An “Achilles’ heel” of shape memory materials is that shape transformations triggered by an external stimulus are usually irreversible. Here we present a new concept of reversible transitions between two well-defined shapes by controlling hierarchic crystallization of a dual-network elastomer. The reversibility was demonstrated for different types of shape transformations including rod bending, winding of a helical coil, and widening an aperture. The distinct feature of the reversible shape alterations is that both counter-shapes are infinitely stable at a temperature of exploitation. Shape reversibility is highly desirable property in many practical applications such as non-surgical removal of a previously inserted catheter and handfree wrapping up of an earlier unraveled solar sail on a space shuttle.

1:03PM Q45.00010 Inscribing dynamical patterns within heterogeneous self-oscillating gels., ANNA C. BALAZS, VICTOR V. YASHIN, Chemical Engineering Department, University of Pittsburgh, Pittsburgh, PA 15261, SEIICHI SUZUKI, RYO YOSHIDA, Department of Materials Engineering, Graduate School of Engineering, The University of Tokyo, Tokyo, 113-8656, Japan — Grafting the ruthenium catalyst to the network of swollen chemo-responsive polymer gel creates a new class of materials, which exhibit the autonomous, coupled chemical and mechanical oscillations induced by the ongoing Belousov-Zhabotinsky (BZ) reaction. The mechanical oscillations occur due to the hydrating effect of the oxidized Ru that causes the gel to swell and de-swell repeatedly. It was predicted previously that compartmentalization of BZ gels in a nonresponsive gel matrix would enable a researcher to create gel-based devices with the functionality inscribed by the configuration of the Ru-containing patches. Recently, the heterogeneous gels were fabricated that encompass the disk-shaped BZ patches. It was demonstrated experimentally for the first time that the direction of propagation of the chemo-mechanical waves in an array of the BZ patches can be controlled by varying the ruthenium content and size of the patches. Here, we present the results of computational modeling of such heterogeneous self-oscillating gels. We discuss how the catalyst concentration, patch size, and inter-patch distance affect the synchronization of oscillations in the neighboring BZ gels, and how the synchronization effects can be utilized to control the dynamical behavior of the entire system.

1:15PM Q45.00011 Swelling instabilities in patterned, microscale gels, RYAN TOOMEY, SAMUEL DUPONT, University of South Florida, NONE TEAM — Hydrogels facilitate reconfigurable structures with response integrated at the material level. Response is engendered by a competing mechanism: the elasticity of the network counterbalances expansion by the solvent. If the strength of expansion can be controlled by an environmental cue, the hydrogel can be adjusted in situ. The equilibrium state occurs when the osmotic stress exerted by the solvent in the gel equals the osmotic pressure of the solvent outside the gel. For a free structure, the equilibrium state corresponds to homogenous swelling. If a free surface of the gel is mechanically constrained, however, the dimensions available for the relief of the osmotic stress are reduced, resulting in non-uniform or inhomogeneous swelling. In this study, we demonstrate how mechanical constraints impose differential gel swelling and buckling in patterned gels. Depending on the initial geometry of the constrained gel, three general modes of swelling-induced deformation can be observed: lateral differential swelling, bulk sinusoidal buckling, and surface wrinkling. Through confocal microscopy and 3D image rendering, the mechanics of swelling has been evaluated in the context of linear elasticity theory.

1:27PM Q45.00012 Thermoresponsive hydrogels from ABC triblock terpolymers, CAN ZHOU, TIMOTHY LODGE, MARC HILLMYER, Department of Chemistry, University of Minnesota, Twin City — We have prepared novel thermoreversible ABC hydrogels from poly(ethylene-alt-propylene)-b-poly(ethylene oxide)-b-poly(N-isopropylacrylamide) (PEP-PEO-PNIPAm) triblock terpolymers. The terpolymers form micelles in water at low temperatures with hydrophobic PEP cores surrounded by hydrophilic PEO-PNIPAm coronas, and these micelles subsequently associate to form a hydrogel upon heating above the lower critical solution temperature (LCST) of PNIPAm. The separation of micellization and gelation leads to the formation of a two-compartment network with exclusively bridging conformations for the PEO midblocks. Therefore, gelation can be achieved at a much lower concentration, with better mechanical properties and a sharper sol-gel transition, when compared with ABA triblock copolymer hydrogels from PNIPAm-PEO-PNIPAm. The results highlight the intricate nanostructures and new properties available from ABC terpolymer hydrogels.

1:39PM Q45.00013 Single Quantum Dot Tracking in Heterogeneous Polyacrylamide Hydrogels, CHEOL HEE LEE, ALFRED CROSBY, RYAN HAYWARD, TODD EMRICK, University of Massachusetts Amherst — Structural heterogeneity within polymer gels plays an important role in determining their material properties, yet is difficult to characterize by established methods. Single particle tracking measurements can provide highly localized information on the diffusion dynamics of tracer particles, and therefore on the material properties of the medium. We use tailored core-shell quantum dots (QDs) with hydrophilic ligands to characterize polyacrylamide hydrogels with varying crosslink density. We find that QDs show sub-diffusive behavior and non-Gaussian displacement distributions, consistent with prior reports on diffusive behavior in other heterogeneous media. We also consider the distribution of particle caging times, which is dictated by the potential energy barriers to escape pores, and therefore provides insight into structural heterogeneity. Specifically, we find that gels with a higher density of crosslinks yield broader distributions of caging times, indicating greater heterogeneity of these networks.

1:51PM Q45.00014 Modeling Photo-Reconfiguration and Directed Motion of Spirobenzopyran- Containing Polymer Gels, OLGA KUKSENOK, ANNA C. BALAZS, University of Pittsburgh — We develop a computational model to simulate the behavior of photo-responsive polymer gels that contain spirobenzopyran (SP) chromophores. Using this model, we design three-dimensional samples with dynamically reconfigurable morphologies and photo-induced motility. In the dark, the SP moieties assume an open ring conformation and are hydrophilic; under illumination with blue light, the chromophores assume a closed ring conformation and are hydrophobic. This collapse of the gels is caused by the decrease in hydration due to conformational changes and not by a light-induced heating of the polymer network. We demonstrate that these gels can be effectively patterned remotely and reversibly with light by illuminating the sample through photomasks. We also show that by introducing variations in crosslink density within the gels during their preparation, as well as introducing temperature gradients, we have additional means of guiding the dynamic behavior of these versatile, responsive systems. Furthermore, we demonstrate that one can use a mobile light source to move multiple gel pieces to a specific location. The results point to a novel method for controlling the self-organization of soft, reconfigurable materials.

2:03PM Q45.00015 Gelation of Copolymers Photo-crosslinked by Pendent Benzophenones, SCOTT CHRISTENSEN, RYAN C. HAYWARD, UMass - Amherst Polymer Science and Engineering — Copolymers containing pendent benzophenone (BP) groups provide a simple and powerful route to crosslinkable polymer films. While the solution state photo-chemistry of BP is well established, and crosslinking of polymers blended with BP has been studied in detail, the process of crosslinking by covalently attached BP has received comparatively little attention. We have prepared copolymers of BP with several different monomers, and studied gelation as a function of BP content and degree of photochemical conversion. Understanding the influence of polymer chemistry on crosslinking efficiency allows the appropriate choice of materials for nanostructured photo-crosslinkable polymer films and reactive polymer blends.

Wednesday, February 29, 2012 11:15AM - 2:15PM – **Session Q46 GQI: Invited Session: Quantum Information Processing in Diamond 160AB**

11:15AM Q46.00001 Single spins in diamond: scalable quantum registers and nanoscale sensors, FEDOR JELEZKO, Institute of Quantum Optics, Ulm University — Ability to detect single atoms is a key element of several key technologies of including quantum information processing, communications as well as nanoscale imaging and sensing. Usually single atom control techniques are limited to low temperature operation. In this talk we will show that single spins associated with nitrogen-vacancy defects diamond (NV centers) can be used as nanoscale magnetic field sensor allowing detecting magnetic moment associated with single electrons under ambient conditions. We also show that coupled arrays of spins can be used as building blocks for scalable quantum registers.

11:51AM Q46.00002 Towards large-scale quantum computing using spins and photons on a chip, KAI-MEI FU, University of Washington — Nitrogen-vacancy (NV) centers in diamond are attractive candidates for quantum bits for quantum information processing. Theoretically it should be possible to build large-scale quantum optical networks with the NV-diamond system. We report HP Labs' recent results toward coupling chip-based optical cavities to negatively charged NV centers in two systems: all diamond micro-ring cavities coupled to native NV centers and GaP micro-ring cavities coupled to near surface centers formed by implantation and annealing. In both systems we observe an enhancement of the spontaneous emission rate into the NV zero-phonon line. Additionally we will discuss recent results in engineering the optical properties of near-surface NV centers suitable for photonic coupling.

12:27PM Q46.00003 Probing the motion of a mechanical resonator via coherent coupling to a single spin qubit, J.G.E. HARRIS, Departments of Physics and Applied Physics, Yale University, New Haven, CT, 06520, USA — Mechanical systems can be influenced by a wide variety of extremely small forces, ranging from gravitational to optical, electrical, and magnetic. If the mechanical resonator is scaled down to nanometer-scale dimensions, these couplings can be harnessed to monitor and control individual quantum systems. In this talk, I will describe experiments in which the coherent evolution of a single electronic spin associated with a Nitrogen Vacancy (NV) center in diamond is coupled to the motion of a magnetized mechanical resonator. Specifically, we have used coherent manipulation of the NV spin to sense the resonator's Brownian motion under ambient conditions. Potential applications of this technique include the detection of the zero-point fluctuations of a mechanical resonator, the realization of strong spin-phonon coupling at a single quantum level, and the implementation of quantum spin transducers.

1:03PM Q46.00004 Preparation, single-shot readout and long-distance coupling of solid-state quantum registers, HANNES BERNIEN, Kavli Institute of Nanoscience Delft — A key challenge in quantum science is to robustly control and to couple long-lived quantum states in solids. In this talk, we report on our latest advances towards realizing long-distance quantum networks with spins in diamond. First, we demonstrate preparation and single-shot measurement of a quantum register containing up to four quantum bits [1]. Projective readout of the electron spin of a single NV center in diamond is achieved by resonant optical excitation. In combination with hyperfine-mediated quantum gates, this readout enables us to prepare and measure the state of multiple nuclear spin qubits with high fidelity. We show compatibility with qubit control by demonstrating initialization, coherent manipulation, and single-shot readout in a single experiment on a two-qubit register, using techniques suitable for extension to larger registers. Second, we observe quantum interference of photons emitted by two spatially separated NV centers [2]. By using electrical tuning of the optical transition frequencies, we are able to observe such interference even for initially dissimilar centers, indicating a viable path for scaling towards a multi-node diamond-based quantum network. We will present these results, along with our most recent data, and discuss the prospects of realizing quantum networks with NV centers in diamond in the near future.

1:39PM Q46.00005 Electrical tuning of single-photon emission in diamond devices¹, LEE C. BASSETT², Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — For quantum information applications, nitrogen-vacancy (NV) centers in diamond combine many of the advantages of atomic systems (optical access, millisecond spin-coherence times) with the engineering flexibility of solid-state devices. Recent demonstrations of coherent coupling between photons and individual NV-center spins [1,2] provide a route to integrating NV-center qubits within photonic networks and for on-demand generation of entangled single-spin/single-photon pairs. Such applications require the ability to tune the NV-center zero-phonon optical transitions, to compensate for natural sample inhomogeneities which perturb the electronic orbital states. Here we demonstrate the ability to electrically control the orbitals of individual NV centers by applying voltages to micron-scale surface gates [3]. Surprisingly, the local electric field experienced by an NV center is significantly enhanced by a photoinduced space charge resulting from photoionization of deep donor impurities within the diamond, even in high-purity single-crystal material (< 5 ppb nitrogen content). Since the photoinduced electric fields are reproducible as a function of gate voltage and are predominantly directed perpendicular to the diamond surface, we can harness them to obtain three-dimensional control of the local electric field vector with surface gates alone. To demonstrate this technique, we tune the excited-state orbital doublet of a strained NV center to degeneracy, as required for some spin-photon entanglement protocols [2], and then adjust the optical transition frequency, showing that we can tune multiple NV centers to have the same degenerate transition energy. This method should enable the coherent coupling of multiple NV center spins to indistinguishable photons within a scalable photonic network.

11:15AM Q47.00001 Heterogeneous 3D Assembly of DNA-encoded Quantum Dots and Gold Nanoparticles¹, DAZHI “PETER” SUN, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory — We report the heterogeneous assembly of quantum dots (QDs) and gold nanoparticles (AuNPs) into three-dimensional (3D) superlattices by means of DNA encoding. CdSe/ZnS core-shell QDs were functionalized with stranded (ss) DNA to obtain a stable aqueous dispersion of QD-DNA conjugates, which maintains the optical properties of the original QDs. By introducing AuNPs modified by complementary ssDNA, QD-AuNP aggregates were assembled. Using synchrotron-based small angle X-ray scattering, we found that QD-AuNP assemblies form a body center cubic (BCC) lattice, while each nanoparticle type, QD and AuNP, are positioned in a simple cubic (SC) manner. Distance-dependent optical property of QDs in heterogeneous superlattices was studied by time-resolved fluorescence spectroscopy. The potential applications of the above optically-active nanosystems will also be discussed.

11:27AM Q47.00002 Self-Assembly of Octopus Nanoparticles into Pre-Programmed Finite Clusters¹, JONATHAN HALVERSON, ALEXEI TKACHENKO, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY 11973 — The precise control of the spatial arrangement of nanoparticles (NP) is often required to take full advantage of their novel optical and electronic properties. NPs have been shown to self-assemble into crystalline structures using either patchy surface regions or complementary DNA strands to direct the assembly. Due to a lack of specificity of the interactions these methods lead to only a limited number of structures. An emerging approach is to bind ssDNA at specific sites on the particle surface making so-called octopus NPs. Using octopus NPs we investigate the inverse problem of the self-assembly of finite clusters. That is, for a given target cluster (e.g., arranging the NPs on the vertices of a dodecahedron) what are the minimum number of complementary DNA strands needed for the robust self-assembly of the cluster from an initially homogeneous NP solution? Based on the results of Brownian dynamics simulations we have compiled a set of design rules for various target clusters including cubes, pyramids, dodecahedrons and truncated icosahedrons. Our approach leads to control over the kinetic pathway and has demonstrated nearly perfect yield of the target.

11:39AM Q47.00003 DNA-induced 2D-to-1D Phase Transition of Nanoparticle Assemblies at Liquid-Vapor Interface¹, SUNITA SRIVASTAVA, DMYTRO NYKYPANCHUK, Center for Functional Nanomaterials, Brookhaven National Laboratory, MASAFUMI FUKUTO, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory — We have investigated the structure formation and development for two-dimensional assembly of DNA functionalized nanoparticles at liquid-vapor interface. The adsorption of negatively charged DNA-coated particle to the interface was triggered by a positively charged lipid layer. A normal and in-plane structure of the nanoparticle monolayer were probed using in-situ surface scattering methods, x-ray reflectivity and grazing incidence small angle x-ray scattering. We observed the formation of the hexagonally closed packed (HCP) 2D lattice of nanoparticles due to a combination of electrostatic surface-to-particle attraction and interparticle repulsion. Upon an onset of DNA hybridization between particles the phase transition from HCP order to 1D crystalline structure was observed. The control on the interparticle spacing and monolayer confinement were also examined by changing a salt concentration. Our studies demonstrate novel mechanism for transition from ordered 2D to ordered 1D structure due to the domination of DNA-induced attraction over an electrostatic repulsion and open a route for nano-structure manipulations at the interfaces.

11:51AM Q47.00004 Structural Diversity of DNA-Coated Particle Assemblies, FRANCIS W. STARR, Physics Dept., Wesleyan University, Middletown, CT — Custom designed nanoparticles (NP) or colloids with specific recognition offer the possibility to control the phase behavior and structure of particle assemblies for a range of applications. One approach to realize these new materials is by attaching DNA to a core particle; the hybridization of double-stranded DNA between particles results in the spontaneous assembly of higher-order structures. Control of the assembled state can be achieved by adjusting several parameters, including sequence selectivity, DNA link orientation, DNA length and flexibility, and the balance between the length of links and non-specific repulsive interactions. I will discuss the results of a coarse-grained molecular model for DNA-linked nanoparticles that helps to rationalize experimental findings and demonstrate new routes to control the assembled structure. We examine how the number and orientation of strands affects the structure, phase behavior, and dynamics. We show that it is possible to realize unusual phase diagrams with many thermodynamically distinct phases, both amorphous and crystal. We further examine the parameters that control the pathways of assembly, which are critical to avoid kinetic bottlenecks. Finally, we discuss strategies to create highly anisotropic structures using both isotropic and anisotropic core units.

12:27PM Q47.00005 DNA Mediated Nanoparticle Crystallization: Characterizing How Equilibrium is Reached¹, CHRISTOPHER KNOROWSKI, ALEX TRAVESSET, Department of Physics and Astronomy and Ames Laboratory, Iowa State University, Ames, IA — DNA programmed self-assembly is becoming one of the most powerful tools for designing nanoparticle crystals due to the exquisite control over lattice size and structure achievable. While in recent years the inventory of crystalline structures accessible through DNA programming has grown, our understanding of the dynamical processes that lead to crystallization is still limited. Using MD we simulate the nucleation and growth of DNA programmed nanoparticle crystallization and characterize the different processes that determine the relaxation times leading to equilibrium. In particular, we classify the topological defects and the processes leading to their annihilation. Implications for experiments as well as for achieving single crystals are also discussed.

12:39PM Q47.00006 Packing of DNA-assembled Nanocubes and Nanooctahedra¹, FANG LU, YUGANG ZHANG, KEVIN YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY, 11973, DANIEL VAN DER LELIE, Center for Agricultural and Environmental Biotechnology, Research Triangle Institute International, Research Triangle Park, NC, 12194, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory, Upton, NY, 11973 — Nanoparticle shape has a profound effect on assembly behavior. However, the contribution of surface-attached molecules can significantly modulate the packing of nanoscale objects, inducing phases markedly different from the known packing rules of macroscopic objects. Our studies uncover the phase behavior of nanocubes and nanooctahedron assembled by DNA-mediated interactions into three-dimensional structures, which were probed in-situ by small angle x-ray scattering. We observed that the packing of these nanoscale anisotropic objects depends strongly on the details of the DNA linkages. Using electron microscopy and optical spectroscopy, we elucidate the factors that drive assembly and dictate the spatial organization of the nano-objects. The relationship between particle shape and the mechanism of phase formation for nanocubes has been also investigated.

12:51PM Q47.00007 Making DNA competitive: a new strategy to improve the self-assembly properties of DNA-coated particles, MIRJAM LEUNISSEN¹, FOM Institute AMOLF, BORTOLO MOGNETTI², DAAN FRENKEL³, University of Cambridge — We present a new approach to widen the normally very narrow temperature window for equilibrium self-assembly (e.g. crystallization) of DNA-coated particles. Using Monte Carlo simulations, we first show that not only enthalpic but also entropic effects - due to the multi-bond character of the DNA-mediated interactions - play an important role in the overall binding properties of the particles. We then outline a new strategy that exploits the competition between different types of inter-particle DNA linkages to achieve a temperature-dependent switching of the dominant bond type. Depending on the length ratio of the DNA constructs, the bond switching is either energetically driven or controlled by a combinatorial entropy gain, which arises from the large number of possible binding partners for each DNA strand. Importantly, the resulting particle interaction is less strongly temperature dependent than in "conventional" systems with only one bond type, thus enhancing the experimental control over self-assembly. Finally, we will also show that in general stable gas-liquid separation is expected to occur only for particles smaller than a few tens of nanometers, which suggests that nanoparticles and micrometer-sized colloids will follow different routes to crystallization.

1:03PM Q47.00008 DNA Regulated Clusters: Structure and Self-limiting Assembly¹, CHENG CHI, Center for Functional Nanomaterials, Brookhaven National Laboratory, FERNANDO VARGAS LARA, FRANCIS STARR, Physics Department, Wesleyan University, ALEXEI TKACHENKO, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory — We have investigated the structural details of nanoparticle clusters assembled by flexible DNA linkers in dimer clusters using electron microscopy, in-situ x-ray scattering and optical methods. The observed dependence of interparticle distance on a DNA length significantly deviates from the predictions for single chain linkages and previous measurements for superlattices. The observed effect is attributed to a large solid angle of interparticle contact, in agreement with computational results. Our studies further reveal the non-monotonic decrease of interparticle distance for the longer linkers; that suggests nanoparticles confinement by hybridized linkers from opposite particles' hemispheres. The effect is accompanied by inhibited development of nanoclusters and results in a self-limited cluster assembly. The mechanism of dimer formation was investigated in details using the optical methods.

¹Research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

1:15PM Q47.00009 Kinetics of the Association of DNA Coated Colloids, KUN-TA WU, LANG FENG, Center for Soft Matter Research, New York University, RUOJIE SHA, Chemistry Department, New York University, REMI DREYFUS, Complex Assemblies of Soft Matter, CNRS-Rhodia-UPenn UMI 3254, ALEXANDER GROESBERG, Center for Soft Matter Research, New York University, NADRIAN SEEMAN, Chemistry Department, New York University, PAUL CHAIKIN, Center for Soft Matter Research, New York University, CENTER FOR SOFT MATTER RESEARCH, NEW YORK UNIVERSITY TEAM, CHEMISTRY DEPARTMENT, NEW YORK UNIVERSITY COLLABORATION, COMPLEX ASSEMBLIES OF SOFT MATTER, CNRS-RHODIA-UPENN UMI 3254 COLLABORATION — The self-assembly of DNA coated colloidal particles opens a door to complex colloidal architecture. To understand how particles aggregate due to DNA hybridization between particles is the key to program colloidal aggregation. In this study, we investigate theoretically and experimentally the aggregation time of micron scale particles as a function of DNA coverage and the ion concentration I . Our particles coated with streptavidin can attach $\sim 70,000$ biotinylated DNA molecules, which have a double strand with 49 base pairs and an 11 base sticky end. At $I = 60$ mM, particles 100% fully covered with DNA show an aggregation time of $\tau = 6$ minutes. For 10% DNA covered particles at $I = 35$ mM, $\tau = 57$ hours. A simple model based on the reaction limited aggregation and electrical repulsion for DNA hybridization is developed and tested. These experiments and the model also allow us to use the microscopic colloidal aggregation to measure nanoscopic hybridization rates.

1:27PM Q47.00010 Phase Behavior and Magnetic Response of DNA-mediated Gold and Iron Oxide Nanoparticle Assemblies¹, YUGANG ZHANG, FANG LU, KEVIN G. YAGER, Center for Functional Nanomaterials, Brookhaven National Laboratory, DANIEL VAN DER LELIE, Center for Agricultural and Environmental Biotechnology, Research Triangle Institute International, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Laboratory — Gold nanoparticles (NPs) have long been long served as model systems to study phase behavior of DNA-assisted NP assemblies. Incorporation of different types of nano-objects into DNA-NP systems opens attractive possibilities for the material design. Furthermore, it also allows enriching a self-assembly behavior by an introduction of non-specific yet controllable interparticle interactions. Herein, we report the DNA-mediated assembly of a heterogeneous system comprising gold and superparamagnetic iron oxide (IO) NPs. We systematically studied the phase diagram of the assembled systems by varying a system's composition, DNA design and environmental conditions. Our studies show that by controlling a balance between non-specific and DNA-recognition interactions via system design the assembled phase can be switched between a face-centered cubic (fcc) structure of a IO assembly and a superlattice formed by Au-IO core-shells clusters. We also observed that structure of assemblies is responsive to the magnetic field.

¹Research was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, under Contract No. DE-AC02-98CH10886.

1:39PM Q47.00011 Modeling of DNA-Directed Colloidal Self-Assembly and Crystallization, TING LI, RASTKO SKNEPNEK, ROBERT J. MACFARLANE, CHAD A. MIRKIN, MONICA OLVERA DE LA CRUZ, Northwestern University — A series of design rules have recently been developed for using gold nanoparticles conjugated with a dense layer of double stranded DNA chains to assemble a wide variety of nanoparticle superlattice structures [1]. Key design parameters for obtaining different structures in a binary system were shown to be the ratio of the hydrodynamic radii of the DNA-conjugated particles, the ratio of the number of DNA strands per particle, and the self- or non-self-complementary nature of the DNA sequences guiding the assembly process. Guided by those experiments, we have built a coarse grained model that faithfully mimics relative design parameters in the experimental system. Working with nanoparticles in the size range from 8nm to 15nm, overall DNA-nanoparticle hydrodynamic radii of 10nm to 30nm, and the number of DNA strands per particle between 30 and 100, we have developed a simulation method that confirms that these design rules can be used to assemble a variety of different crystal structures. In particular, we have identified FCC, BCC, CsCl, AlB_2 and Cr_3Si structures. With these data, we have constructed a detailed phase diagram that closely corresponds to the experimentally obtained phase diagram developed in ref. [1]. [1] R. J. Macfarlane, B. Lee, M. R. Jones, N. Harris, G.

1:51PM Q47.00012 DNA coated rods: pure Biological materials for self assembly studies, RAFAEL CABANAS, SETH FRADEN, Brandeis University, DR. ERIKA EISER GROUP CAMBRIDGE UNIVERSITY, UK. COLLABORATION — We will present a way of coating Fd virus, a model of colloidal liquid crystal, with DNA. The DNA coating provides new interesting tunable properties to control the liquid crystalline behavior.

2:03PM Q47.00013 Linear DNA-linked colloidal chains: a model to visualize polymer dynamics¹, SIBANI BISWAL, JULIE BYROM, DANIEL DU, Rice University — We present the development of synthetic materials consisting of chains of DNA-linked paramagnetic colloids that have rigidity and length specificity. These chains have demonstrated capability for folding and self-assembly. This is classic bead-spring-bead model can be a model system to visualize polymer dynamics. Here, I will describe the formation mechanism and stability of these DNA-linked magnetic particle chains. I will also describe a model that describes the total energy landscape that describes the inter-particle interactions and provides a workable theory toward the optimization of experimental parameters in synthesizing more stable and reliable colloidal assemblies. In addition to stability, we will also present the use of a colloidal worm-like chain (WLC) model system to describe chain dynamics. We measure bending rigidity by monitoring the thermal fluctuations of the chains. We show that the persistence length of the chains can be tuned from 1 to 50 nm ($L/LP = 0.002 - 0.1$), by changing the length of the DNA used to link adjacent particles from 75 to 15 bases. We also will show that the bending relaxation dynamics of these chains, which match well with theoretical predictions, further supporting the validity of using these colloidal chains as models for semiflexible polymer systems in both equilibrium and dynamic studies.

Wednesday, February 29, 2012 11:15AM - 2:03PM – Session Q48 DPOLY: Polymer Blends and Crystallization 161

11:15AM Q48.00001 How Pure Components Control Polymer Blend Miscibility¹, RONALD WHITE, JANE LIPSON, Dartmouth College, JULIA HIGGINS, Imperial College, London — We present insight into some intriguing relationships revealed by our recent studies of polymer mixture miscibility. Applying our simple lattice-based equation of state, we discuss some of the patterns observed over a sample of experimental blends. We focus on the question of how much key information can one determine from a knowledge of just the pure components only, and further, on the role of separate enthalpic and entropic contributions to the miscibility behavior. One interesting correlation connects the value of the difference in pure component energetic parameters with that of the mixed segment interactions, suggesting new possibilities for predictive modeling. We also show how in some cases these two parameter groupings act as separate controls determining the entropy and enthalpy of mixing. Also discussed are the different patterns exhibited for UCST-type and LCST-type blends, these being revealed in some cases by simple examination of the underlying microscopic parameters.

11:27AM Q48.00002 Tailoring Co-continuous Nanostructured Morphologies in Polymer Blends, LE LI, SUNG-WOO HONG, XIAOBO SHEN, RYAN HAYWARD, THOMAS RUSSELL, University of Massachusetts Amherst — We describe a simple approach to prepare thin films of polymer mixtures with co-continuous morphologies having characteristic length scales down to tens of nanometers based on spinodal phase separation. The degree of immiscibility between polystyrene (PS) and poly(2-vinylpyridine) (P2VP) is tuned by incorporating styrene monomers into the P2VP backbone to yield a random copolymer, thereby tailoring the nonfavorable interactions between the two components. The size scale of the co-continuous morphology is controlled by varying the molecular weights of the components and the film thickness. This strategy is shown to be robust in that the process involves a simple solution-casting; the co-continuity of the morphology occurs provided the solvent dissolves both components; and the co-continuous morphology is insensitive to the substrate surface chemistry. Porous membranes with continuous channels and gradient co-continuous structures can also be generated from the phase separated blend films.

11:39AM Q48.00003 Structure and elasticity of crosslinked polymer blends, BING LU, University of Illinois at Urbana-Champaign, XIANGJUN XING, Shanghai Jiao Tong University, PAUL GOLDBART, Georgia Institute of Technology — We consider a blend of mutually incompatible homopolymer species, A and B, that are randomly crosslinked to form a network. In such a network there is a competition between the repulsion of the A and B polymers (which favors the demixing of the two species) and the crosslinking (which prohibits complete demixing) [1,2]. We treat the system by means of a model of flexible polymers, which are permanently crosslinked (with statistics modeled by the Deam-Edwards distribution) and have species-dependent excluded-volume interactions [3]. As expected, the model shows that at sufficiently low temperatures the demixing tendency drives microphase separation, with a characteristic scale set by the network localization length. It also shows that if the system is strained after crosslinking, correspondingly anisotropic microdomains are generated in the pattern of A-B polymer concentration fluctuations trapped in by the network and, furthermore, allows the impact of microphase separation on the elastic properties of the network to be determined.

11:51AM Q48.00004 Assessing the Strength Enhancement of Heterogeneous Networks of Miscible Blends of 1,2-Polybutadiene and Polyisoprene¹, CARL GILLER, American Society for Engineering Education, Washington, D.C., MIKE ROLAND, Chemistry Division, Code 6120, Naval Research Laboratory, Washington, D.C. — At typical crosslink densities of elastomers, failure properties vary inversely with mechanical stiffness, so that compounding entails a compromise between stiffness and strength. Our approach to circumvent this conventional limitation is by forming networks of two polymers that: (i) are thermodynamically miscible, so that the chemical composition is uniform on the nm level; and (ii) have markedly different reactivities for network formation. The resulting elastomer consists of one highly crosslinked component and one that is lightly or uncrosslinked. This disparity in crosslinking causes their respective contributions to the network mechanical response to differ diametrically. Earlier results showed some success with this approach for thermally vulcanized blends of 1,2-polybutadiene and polyisoprene, taking advantage of their differing reactivities to sulfur. In this work we explore networks of this miscible blend formed via UV irradiation with a photoinitiator. The vinyl group in 1,2-polybutadiene has a much greater photo-reactivity than the double bond in polyisoprene, resulting in a disparity in respective degrees of crosslinking, while the thermodynamic miscibility is retained. Mechanical properties of the radiation crosslinked blend are compared to conventional networks.

12:03PM Q48.00005 Compatibilization of polymer blends with star polymers containing a gamma-cyclodextrin core and polystyrene arms¹, C.M. BALIK, Dept. of Materials Science and Engineering, North Carolina State University, A.E. TONELLI, Dept. of Textile Engineering, Chemistry and Science, North Carolina State University, RYAN LIBERT, Dept. of Materials Science and Engineering, North Carolina State University — Cyclodextrins (CDs) are cyclic starch molecules having a hollow central cavity which can be threaded by a polymer to form an inclusion compound. This characteristic is exploited in a new type of compatibilizer: a star polymer with a gamma-CD (g-CD) core and polystyrene (PS) arms (CD-star). The mechanism of compatibilization involves threading of the CD core by a second polymer and solubilization of the threading polymer into a PS matrix by the PS star arms. In principle, the same CD-star polymer can be used to compatibilize blends of several different polymers with PS, provided that the second polymer is able to thread the CD core. We have taken the first step toward demonstrating the generality of this approach by producing compatibilized blends of PS with poly(dimethyl siloxane) (PDMS) or poly(methyl methacrylate) (PMMA) using the same CD-star polymer. Thin spun-cast films of these blends exhibit a nanoscale level of mixing, while spun-cast films of the same blends without CD-star exhibit large-scale phase separation. The number of CD-star molecules that must be threaded onto the polymer chain to achieve compatibilization is larger for PMMA than for PDMS.

12:15PM Q48.00006 Theory of Hydrogen-Bonding in Diblock Copolymer/Homopolymer Blends, ASHKAN DEGHAN, AN-CHANG SHI, McMaster University — The phase behavior and physical properties of hydrogen-bonding diblock copolymer/ homopolymer (AB/C) blends are examined using self-consistent field theory. We consider two methods for modeling the formation of hydrogen bonds between polymer chains. The first using a large negative (attractive) interaction parameter and the second using polymer-polymer complexation. Despite the success of the first model in describing the phase behavior of the system, it fails to correctly predict the change in lamella spacing induced by addition of homopolymer chains, previously shown in many experiments. Using polymer-polymer complexation we were able to qualitatively show the order-order phase transitions and decrease in lamella spacing for the case of strong hydrogen bonding. Our analysis of both methods show that hydrogen bonding of polymer chains should be described by polymer-polymer complexation.

12:27PM Q48.00007 Effect of mid-block on the morphology and properties of PDLA-softblock-PDLA/PLLA Blends, SAHAS RATHI, E. BRYAN COUGHLIN, SHAW LING HSU, University of Massachusetts Amherst — A novel method to overcome the brittleness of PLLA is by kinetically trapping a continuous low T_g amorphous phase. This morphology has been accomplished by exploiting the significant difference in the crystallization temperatures of the neat PLLA versus its stereocomplex with the PDLA isomer. This morphology is formed by blending and co-crystallizing triblock copolymer with a configuration of the form PDLAn- Soft Blockm- PDLAn with PLLA. The type of morphology formed and the improvement in the sample toughness strongly depends on the miscibility of the midblock in the triblock copolymer with the matrix PLLA. This work explores the effect of the chemical nature of the midblock on the stereocomplex crystallization between the PDLA end-blocks and the PLLA matrix polymer and the blend morphology formed. It is found that miscible midblocks give rise to a soft continuous amorphous phase morphology while in case of immiscible midblocks a glassy phase separated amorphous phase morphology is formed. Dramatically different physical properties can be obtained for various PLLA/tri-block copolymer blends giving access to tough, semicrystalline PLLA blends.

12:51PM Q48.00009 Molecular Dynamics Simulations of Polypropylene: Crystallization and Melting¹, MANISH AGARWAL, SHYNO MATHEW, SANAT KUMAR, Columbia University — The crystallization of polypropylene is studied using molecular dynamics (MD), using an all atom force field. Starting from basic ordered arrangements of oligomers, the α and β phases for isotactic polypropylene are recovered, with cell parameters in excellent agreement with crystallographic data. A high pressure phase similar to the smectic phase is also observed. The melting temperatures of these crystals, obtained by isobaric heating, match with the experiments. Oligomers of syndiotactic polypropylene mirror all structural features observed in experiments. The all-trans state is found to be the most stable. The characteristic 2/1 helical structure of syndiotactic polypropylene is also formed along with the all-trans “zigzag” conformation.

1:03PM Q48.00010 Molecular simulation of plastic deformation of semicrystalline polyethylene, JUNMO KIM, SANGHUN LEE, GREGORY RUTLEDGE, Massachusetts Institute of Technology — The detailed structure and the high anisotropy of semicrystalline polymer at the lamellar length scale play an important role in determining its mechanical response. In this study, we performed molecular dynamics simulation of semicrystalline polyethylene under various industrially important deformations, such as extension, compression, and shear, to characterize the plastic deformation response. The semicrystalline polyethylene model employed in this study consists of a 1-D alternating stack in the longitudinal z direction of crystalline lamellae and interlamellar noncrystalline domains, that are infinite in the lateral x and y directions. The molecular dynamics simulations are carried out at the temperature of 350K using united atom model and two deformation strain rates (fast and slow) are considered in each deformation. Stress-strain curves, elastic moduli, yield stresses and so on, are examined under each deformation and compared to each other. In addition, the entanglement statistics of semicrystalline polyethylene under various deformation modes are investigated using the Z-code.

1:15PM Q48.00011 ABSTRACT WITHDRAWN —

1:27PM Q48.00012 Digestive Ripening: A Quantitative Thermodynamic Analysis of Stable Nanocrystals, MICHAEL CLARK, SANAT KUMAR, Columbia University, IGAL SZLEIFER, RIKKERT NAP, Northwestern University — Previous studies have shown that stable, monodisperse nanocrystals (NCs) have been produced using strongly binding surfactants, e.g. Au NCs with alkylthiols or Co NCs with oleic acid, to name a few. Through a first-principles theoretical investigation, we develop the full quantitative thermodynamic expression for the state of these surfactant-coated NCs. The general free energy expression allows for the crystal free energy, the surfactant binding energy, surfactant conformational entropy, and the surfactant interactions with other surfactants through excluded volume, solvent depletion, and energetic interactions between surfactant molecules. The energetics of the surfactant chains are treated quantitatively through Single Chain Mean Field theory, which determines the optimal number of grafted surfactants on the surface of an R-sized NC. Then, the size distribution function $f(R)$ is calculated to determine the most favorable NC size and the equilibrium polydispersity. The theoretical conclusions will be compared quantitatively with experimental results. The full thermodynamic expression allows a parametric study of experimentally relevant conditions that govern whether Ostwald ripening vs. digestive ripening vs. dissolution will occur in a given nanocrystal-surfactant system.

1:39PM Q48.00013 Morphology and Shear Viscosity for a Phase-separating Polymer Blend of Polybutadiene and Polyisoprene under Simple Shear Flow¹, XIA DONG, FASHENG ZOU, CHARLES C. HAN, Institute of Chemistry Chinese Academy of Sciences — The domain structure and shear viscosity of a phase-separated polymer blend of polybutadiene /polyisoprene are investigated with optical microscopy, light scattering, and rheometry. At the steady shear state, the shear-induced structures can be the nearly spherical droplets, the partially interconnected domains, the typical string-like domains, or the string-like domains with blurred interface, depending on the shear rate. The steady shear viscosity displays a rather non-Newtonian fluid behavior. In the transient flow experiments, the time dependence of viscosity and morphology after a stepwise increase of shear rate is studied and found to mainly depend on the final shear rate. In particular, as long as the final structures are the partially interconnected domains, the morphology evolution proceeds in the same way and the behaviors of the corresponding shear viscosity are similar.

1:51PM Q48.00014 Dynamics of Polymer Blend Film Formation During Spin Coating¹, YOUNNA MOUHAMED, NIGEL CLARKE, RICHARD A.L. JONES, MARK GEOGHEGAN, University of Sheffield — Spin casting is a process broadly used to obtain a uniform film on a flat substrate. A homogeneous film results from the balance between centrifugal and viscous forces. Here we revisit the Meyerhofer model of the spin casting process by taking in account the centrifugal forces, a uniform time dependent evaporation rate, and account for the changes in viscosity using the Huggins intrinsic viscosity. Time resolved light reflectometry is used to monitor the thickness changes of a polystyrene-poly(methyl methacrylate) (which we denote as PS and PMMA) film initially dissolved in toluene and spin cast for ten seconds at 1000 rpm. The experimental data are in good agreement with the model. We also investigate how the volume fraction of PS and PMMA influences the thinning of the film during spin casting. A distinct change in the temporal evolution of thickness as a function of time delimits the first phase of the spin casting process where centrifugal forces are dominant from a second phase dominated by the solvent evaporation. This hypothesis is supported by in-situ off specular scattering data. The time at which this change from centrifugal to evaporation-dominated behaviour is delayed as the volume fraction of PMMA increases.

Session Q49 DMP DPOLY: Focus Session: Organic Electronics and Photonics - Photophysics and Excited State Dynamics 162A

11:15AM Q49.00001 Hybrid Phononiton in Organic-Semiconductor Materials¹, DAVID FACEMYER, QUE HUONG NGUYEN, Marshall University — In this work electronic structures and optical properties of organic-inorganic phononiton, a new elementary excitation existing in heterostructures combining both organic and semiconductor materials, are studied. In those systems, Wannier-Frenkel hybrid exciton has unique and interesting properties that can improve the efficiency of optical materials. When an organic-semiconductor combined heterostructure is illuminated by high-intensity electromagnetic radiation with the frequency of the photons at or near the resonance frequency of the Wannier-Frenkel exciton, we obtain a macroscopically occupied system of hybrid polaritons that further interacts with phonons which will in turn generate the hybrid phononiton. Electronic structure, energy and dispersion relation of phononitons are theoretically determined. By analyzing the interactions between the hybrid exciton, photons and phonons, the conditions for phononiton formation are discussed.

11:27AM Q49.00002 Effect of structural distortion and polarization in localization of electronic excitations in organic semiconductor materials, IFFAT NAYYAR, Theoretical Div., Los Alamos National Lab, Los Alamos, NanoScience Technology Center and Dept. of Physics, University of Central Florida, Orlando, ENRIQUE BATISTA, Theoretical Div., Los Alamos National Lab, Los Alamos, SERGEI TRETIAK, Theoretical Div. and Center for Integrated Nanotechnologies, Los Alamos National Lab, Los Alamos, AVADH SAXENA, DARRYL SMITH, RICHARD MARTIN, Theoretical Div., Los Alamos National Lab, Los Alamos — Organic polymers find varied applications in optoelectronic devices such as solar cells, light emitting diodes and lasers. Detailed understanding of charge carrier transport by polarons and excitonic energy transfer producing singlet and triplet excitations is critical to improve their efficiency. We benchmarked the ability of current functional models to describe the spatial extent of self-trapped neutral and charged excitations for MEH-PPV owing to its superior luminescence and experimental evidence. Now we are interested in distinguishing between two distinct origins leading to localization; spatial localization of the wavefunction by itself on the undistorted geometry and localization of the wavefunction assured by distortion of the structure during its relaxation. We suggest localization is produced by electronic rearrangements and character of the functional. We also observe that different functionals place the highest occupied and lowest virtual orbitals at different positions in the energy band diagram based on their ability to predict the extent of localization of these states.

11:39AM Q49.00003 The Effect of LUMO Level Offset on the Electron Dissociation Rates in Low Bandgap Polymer Heterostructures, MATTHEW SFEIR, Brookhaven National Laboratory, DEANNA RODOVSKY, Konarka Technologies, Inc./National Institute of Standards and Technology, JASON AZOULAY, GUILLERMO BAZAN, University of California, Santa Barbara, JEFFREY PEET, Konarka Technologies, Inc. — In order to maximize the efficiency of polymer/fullerene bulk heterojunction solar cells, the voltage lost when the electron transfers from the polymer to the fullerene must be minimized. While the magnitude of this loss will significantly impact the maximum attainable efficiency of this technology, there have been relatively few attempts to quantify the dependence of the electron transfer rate and yield on the driving force for electron transfer. In order to isolate the effect of electrochemical potential difference on the exciton dissociation rate, we present results of photophysical measurements of a low bandgap copolymer mixed with a series of fullerene based acceptor materials in a bulk heterojunction geometry. The LUMO level of the acceptor material is varied relative to the polymer's so that the effect of the energy offset on the electron dissociation rate can be determined. Using photoluminescence and transient absorption measurements, we find that the exciton quenching rate varies systematically with increasing energy offset. We examine the mechanism of charge carrier generation by correlating the exciton quenching with charge carrier generation.

11:51AM Q49.00004 First principles study of optical and electronic properties of anthradithiophene based organic conductors, FAYE BARRAS, GUENTER SCHNEIDER, Oregon State University — Functionalized anthradithiophene (ADT) derivatives are high performance organic conductors where the addition of side groups such as triethylsilyl ethynyl (TES) to the ADT backbone induces a change in the morphology from a herringbone to a planar crystal structure in which improved intermolecular π -orbital overlap increases carrier mobility. Bulk type-II heterojunctions can be formed using matched pairs such as ADT-TES-F (donor) and ADT-TIPS-CN (acceptor). We report electronic and optical properties calculated from ab initio density functional theory (DFT) calculations for ADT derivatives. Exciton and exciplex formation and charge separation in ADT bulk heterojunctions is studied using 2 molecule model calculations for ADT-TES-F (donor) and ADT-TIPS-CN or C₆₀ (acceptor). We compare our results to available experimental results such as photo luminescence and photocurrent measurements.

12:03PM Q49.00005 Ultrafast exciton energy transfer from giant nanocrystals to layered J-aggregate films, ASJA RADJA, HUE NGUYEN, Department of Physics, The University of Texas at Dallas, Richardson, TX, 75080, JENNIFER HOLLINGSWORTH, Chemistry Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, L, ANTON MALKO, Department of Physics, The University of Texas at Dallas, Richardson, TX, 75080 — The integration of organic and inorganic materials at the nanoscale offers the possibility of developing new photonic devices that could combine the advantages of both classes of materials. Particularly interesting for such applications is a new class of core/shell CdSe/CdS nanocrystals (NQDs) with large number of shell monolayers (MLs) that are photostable, non-blinking and have an advantage of suppressed non-radiative Auger recombination leading to the existence of bright multiexcitonic (MX) states. However, due to large MLs thicknesses, the extraction of charge through such shells may pose considerable problems. In this work we studied hybrid structures composed of “giant”, ($\#ML > 10$) CdSe/CdS NQDs anchored on top of thin layers of strongly absorbing J-aggregates (JA) of cyanine dye (TDBC). We performed time-resolved and steady-state photoluminescence (PL) measurements to quantify the *excitonic energy transfer* (ET) rates from the gNQDs to JA layer. By varying temperature (from RT to 80K) we observed change in ET rates in accordance with the overlap integral between NQD PL emission and JA absorption. In all cases, ET transfer rates exceeded 99%. Hence, we foresee the utilization of gNQDs in applications in hybrid systems based on energy transfer.

12:15PM Q49.00006 ABSTRACT WITHDRAWN —

12:27PM Q49.00007 Ultrafast multidimensional spectroscopy of P3HT thin films, CONG MAI, NC State University, SINAN CAN, NC State University and Bogazici University, ANNE WATSON, HARALD ADE, KENAN GUNDOGDU¹, NC State University — We report on measurements of morphology dependence of exciton/polaron dynamics in P3HT thin films. Intrachain and interchain electronic coupling has a significant impact on optical and electronic properties of polymers. Due to flexibility of polymers, slight differences in processing results in a variation of morphologies and electronic coupling between the chains. We employ ultrafast multidimensional spectroscopy techniques to resolve the resulting polaron formation dynamics in different polymer thinfilms spin casted from different solvents. Our results suggest, depending on the average conjugation length and crystallinity of the thin film, polaron formation dynamics exhibit spectrally homogeneous or inhomogeneous behavior.

12:39PM Q49.00008 Charge transfer complex in diketopyrrolopyrrole polymers and fullerene blends: Implication for organic solar cell efficiency, D. MOGHE, P. YU, University of Missouri-Columbia, MO, C. KANIMAZHI, S. PATIL, Indian Institute of Science, Bangalore, India, S. GUHA, University of Missouri-Columbia, MO — Copolymers based on diketopyrrolopyrrole (DPP) have recently gained potential in organic photovoltaics. When blended with another acceptor such as PCBM, intermolecular charge transfer occurs which may result in the formation of charge transfer (CT) states. We present here the spectral photocurrent characteristics of two donor-acceptor DPP based copolymers, PDPP-BBT and TDPP-BBT, blended with PCBM to identify the CT states. The spectral photocurrent measured using Fourier-transform photocurrent spectroscopy (FTPS) and monochromatic photocurrent (PC) methods are compared with P3HT:PCBM, where the CT state is well known. PDPP-BBT:PCBM shows a stable CT state while TDPP-BBT does not. Our analysis shows that the larger singlet state energy difference between TDPP-BBT and PCBM along with the lower optical gap of TDPP-BBT obliterates the formation of a midgap CT state resulting in an enhanced photovoltaic efficiency over PDPP-BBT:PCBM.

12:51PM Q49.00009 Dynamic Monte Carlo Modeling of Exciton Dissociation in Organic Donor-Acceptor Solar Cells, MICHAEL HEIBER, ALI DHINOJWALA, University of Akron, Department of Polymer Science — A general dynamic Monte Carlo model for exciton dissociation at a donor-acceptor interface including exciton delocalization and hot geminate pair dissociation has been developed to model the experimental behavior observed for the P3HT:PCBM system and predict the theoretical performance of future materials systems. The presence of delocalized excitons and the direct formation of separated charge pairs has been recently measured by transient photo-induced absorption experiments, and has been proposed to facilitate charge separation efficiency. The excess energy of the exciton dissociation process has also been observed to have a strong correlation with the charge separation yield for a range of thiophene polymer:PCBM systems, suggesting that a hot charge separation process is also occurring. Hot geminate pair dissociation has been previously theorized as a cause for highly efficient charge separation, however a detailed model for this process has not been implemented and tested. Here, both conceptual models have been implemented into a dynamic Monte Carlo simulation and tested using a model bilayer donor-acceptor system.

1:03PM Q49.00010 Ultrafast Photo Physics of P3HT/PCBM blends for Organic Photovoltaic applications, BILL PANDIT, SANJEEV SINGH, ZEEV VALY VARDENY, Department of Physics and Astronomy, University of Utah, Salt Lake City, Utah, 84112 — We studied the ultrafast dynamics of photoexcitations in pristine polymer films of regio-regular polythiophene, regio-random polythiophene, and their blends with the fullerene derivative C₆₁-PCBM using the pump-probe photomodulation (PM) spectroscopy with ~150 fs time resolution. Our transient PM spectrum covers the broad spectral range of 0.25 – 2.4 eV using two different laser systems; which allows us to simultaneously monitor the dynamics of various photoinduced absorption bands such as intrachain excitons, charge transfer excitons, and polaron-pairs. Surprisingly, we have been able to monitor the decay of intrachain exciton on the polymer chains in films of polymer/fullerene blends, but unable to detect the subsequent generation of polarons in the donor (D) and acceptor (A) materials up to ~ 1 ns. We explain this finding considering that the excitons in the polymer chains form charge transfer excitons upon reaching the D-A interface, rather than undergo a more direct dissociation on the D-A materials. The understanding of charge separation at the D-A interface is crucial for improving the power conversion efficiency of organic solar cell devices. Supported in part by the DOE grant No. DE-FG02-04ER46109.

1:15PM Q49.00011 Can Singlet Fission Enhance the Performance of Organic Solar Cells?¹, J.A. MUNOZ, K. ARYANPOUR, S. MAZUMDAR, Dept of Physics, Univ of Arizona — The high efficiency of pentacene-fullerene (Pc-C₆₀) donor-acceptor solar cells has been ascribed to singlet fission, which generates two spin triplet excitons that each undergo ionization to give two pairs of electrons and holes [1,2]. For triplet ionization to give charge generation, the charge-transfer exciplex in the Pc-C₆₀ heterostructure should be energetically below the the molecular triplet state in Pc. Our initial calculations show that this is not a plausible scenario. We propose an alternate mechanism for the relatively high efficiencies of solar cells constructed from donors such as Pc, based on correlated-electron configuration interaction calculations [3] of ground state and photoinduced charge-transfer.

1:27PM Q49.00012 Exciton self-trapping and Stark effect in the optical response of pentacene crystals from first principles¹, DAVID A. STRUBBE, Department of Physics, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory, SAHAR SHARIFZADEH, JEFFREY B. NEATON, Molecular Foundry, LBNL, STEVEN G. LOUIE, Physics Dept., UC Berkeley; MSD and MF, LBNL — Pentacene is a prototypical organic semiconductor with optoelectronic and photovoltaic applications. It is known that the lowest-energy singlet excitation has a Stokes shift between absorption and emission of about 0.14 eV, but the deformation associated with this self-trapped exciton remains unknown. We begin with a calculation of the optical properties via the first-principles GW/Bethe-Salpeter (BSE) theory [ML Tiago, JE Northrup, and SG Louie, Phys. Rev. B 67, 115212 (2003); S Sharifzadeh, A Biller, L Kronik, and JB Neaton, arXiv:1110.4928 (2011)]. We then study the self-trapping phenomenon via our reformulation of the Bethe-Salpeter excited-state forces approximation of Ismail-Beigi and Louie [Phys. Rev. Lett. 90, 076401 (2003)], which can describe the structural relaxation after optical excitation. Whether excitons in pentacene have charge-transfer character has been controversial in electro-absorption experiments. We use the same BSE analytic derivatives approach to calculate the changes in excitation energies due to an applied electric field to understand this experimental controversy.

¹Support from DOE (DE-AC02-05CH11231) and NSF (DMR10-1006184). Computational resources from NERSC and TeraGrid.

1:39PM Q49.00013 Singlet Fission and Multi-Exciton Generation in Organic Systems, CHARLES MUSGRAVE, University of Colorado — Multi-exciton generation (MEG) has been observed in a variety of materials and might be exploited in solar-cells to dramatically increase efficiency. In tetracene and pentacene MEG has been attributed to singlet fission (SF), however a fundamental mechanism for SF has not been previously described. Here, we use sophisticated ab initio calculations to show that MEG in pentacene proceeds by transition of the lowest optically allowed excited state S1 to a dark state (D) of multi-exciton character, which subsequently undergoes SF to generate two triplets (2×T0). D satisfies the energy requirement for SF ($E_D > 2E_{T0}$) and lies just below S1 in pentacene, but above S1 in tetracene, consistent with the observed thermally activated SF process in tetracene, but no thermal activation in pentacene. While S1 exhibits single exciton character, D shows multi-exciton character comprising two separated electron-hole pairs. Dimer simulations predict S1 excimer formation and that fission of D into triplets proceeds through the excimer. The predicted energetics, wavefunctions and excimer interaction support the proposed mechanism, which accounts for the observed rapid, unactivated SF in pentacene. Results for SF in polyacenes, grapheme nanoribbons, rubrene and carbon nanotubes will be presented.

Session Q50 DPOLY: Focus Session: Dynamics of Polymers: Phenomena due to Confinement

II 162B

11:15AM Q50.00001 New insight into adsorption of polymer melts onto impenetrable surfaces¹, TAD KOGA, PETER GIN, NAISHENG JIANG, CHEN LIANG, ZEXI HAN, Stony Brook University, BULENT AKGUN, SUSHIL SATIJA, NIST, MAYA ENDOH, Stony Brook University — We report the novel structures of irreversibly adsorbed polystyrene (PS) layers composed of six different molecular weights ranging from 30k to 2,000k. Spin cast PS films (originally ~ 100 nm in thickness) prepared onto hydrogen-passivated silicon substrates were annealed at 170 °C for about 50h under vacuum and subsequently rinsed with toluene (a good solvent for PS) thoroughly. X-ray reflectivity results show that the adsorbed layers are well described by a two-layer model: the one is a higher density layer relative to the bulk adjacent to the substrate and the other is a nearly bulk density layer on top of the bottom layer. On the other hand, a single-layer model with the higher density layer is valid for the adsorbed layers composed of low molecular weights PS. We will reveal the origin of the difference, shedding light on a new pathway for the formation of the equilibrium adsorbed polymer layers at the impenetrable interfaces.

¹We acknowledge the financial support from NSF Grant No. CMMI-084626.

11:27AM Q50.00002 Effect of the interfacial interaction on the relaxation of polymer melts in nanofilms, LEI LI, YONGJIN WANG, Department of Chemical Engineering, University of Pittsburgh, JIANING SUN, J.A. Woollam Co. — The relaxation of polymer melts in nanofilms could be orders of magnitude slower than in bulk. To date, the governing mechanism remains unclear on the role of spatial confinement and interfacial interaction. Here we report the experimental results indicating that the polymer-substrate interfacial interaction plays a key role in the relaxation. Two perfluoropolyethers (PFPEs) with the same backbone and different endgroups, one polar and the other non-polar, have been studied. The relaxation of the nanofilms on silicon wafers was characterized by the contact angle measurement. For the PFPE with polar endgroups, the contact angle “relaxes” with time and the relaxation time constant, obtained from KWW model, is ten orders of magnitude higher than that of bulk polymer. However, for the PFPE with non-polar endgroups, the contact angle relaxation was not observed. The experimental results indicate that the relaxation is thermodynamically driven by the attractive interaction between the polar endgroups of the polymers and the polar sites on the solid substrate. The very slow kinetics of the relaxation has been attributed to the heterogeneity of the polymer-solid interfacial interaction and the cooperative nature of the molecular motions during the relaxation.

11:39AM Q50.00003 Differential AC chip calorimeter for in situ investigation of vapor deposited thin films, MATHIAS AHRENBERG, CHRISTOPH SCHICK, HEIKO HUTH, EVGENI SCHOIFET, University of Rostock, Germany, MARK EDIGER, KATIE WHITAKER, University of Wisconsin - Madison, Wisconsin, USA — Physical vapor deposition (PVD) can be used to produce thin films with particular material properties like extraordinarily stable glasses of organic molecules. We describe an AC chip calorimeter for in-situ heat capacity measurements of as-deposited nanometer thin films of organic glass formers. The calorimetric system is based on a differential AC chip calorimeter which is placed in the vacuum chamber for physical vapor deposition. The sample is directly deposited onto one calorimetric chip sensor while the other sensor is protected against deposition. The device and the temperature calibration procedure are described. The latter makes use of the phase transitions of cyclopentane and the frequency dependence of the dynamic glass transition of toluene and ethylbenzene. Sample thickness determination is based on a finite element modeling (FEM) of the sensor sample arrangement. A layer of toluene was added to the sample sensor and its thickness was varied in an iterative way until the model fits the experimental data.

11:51AM Q50.00004 Methyl Methacrylate Polymerization in Nanoporous Matrix: Reactivity and Resulting Properties¹ , HAOYU ZHAO, FATEMA BEGUM, SINDEE SIMON, Texas Tech University — Nanoconfinement is well known to affect the properties of polymers, including changes in the glass transition temperature (T_g). In this work, the focus is on the influence of nanoconfinement on free radical polymerization reaction kinetics and the properties of the polymer produced. Controlled pore glass (CPG) is used as a nanoconfining matrix for methyl methacrylate (MMA) polymerization with pore diameters of 13 nm, 50 nm, and 110 nm. The reaction is followed by measuring heat flow as a function of reaction time during isothermal polymerization at temperatures ranging from 60 °C to 95 °C using differential scanning calorimetry (DSC). After reaction, the properties of the polymer are measured, including T_g , molecular weight, and tacticity. Nanoconfinement is found to result in earlier onset of autoacceleration, presumably due to a decrease in the rate of termination arising from decreases in chain diffusivity in the confined state. In addition, T_g and molecular weight of the resulting PMMA are found to increase. A model of the nanoconfined reaction is able to quantitatively capture these effects by accounting for changes in chain diffusivity, and in native pores, also accounting for changes in intrinsic reaction rates.

¹Funding from the National Science Foundation CMMI 0826437 is gratefully acknowledged.

12:03PM Q50.00005 Polystyrene films confined between gold surfaces , KAREN JOHNSTON, Max Planck Institute for Polymer Research, VAGELIS HARMANDARIS, University of Crete, KURT KREMER, Max Planck Institute for Polymer Research — The properties of thin short-chain polystyrene films between two parallel Au(111) surfaces are studied using a combination of density functional theory (DFT) and classical molecular dynamics (MD) simulations. The chemical interaction with the surface is calculated with DFT and the results are used to develop accurate atomistic classical surface potentials. These potentials are used in the MD simulations to investigate several systems with various film thickness and the effect of increasing confinement on the structural and dynamical properties of the films will be presented. A coarse-grained model is developed and used to study longer-chain polystyrene films and larger systems.

12:15PM Q50.00006 Surface Mobility of Polymeric Systems of Varying Chain Lengths , ROHIT MALSHE, GREGORY TOEPPERWEIN, MARK EDIGER, LIAN YU, JUAN DE PABLO, University of Wisconsin — Thin films of polymeric material can exhibit drastically altered glass transition temperatures, mechanical responses, and overall dynamics as compared to the bulk. Differences in surface and bulk mobility are often cited as a primary explanation for such differences, but it has remained difficult to quantify local mobility as within the film. We have recently shown that decay constants from Mullins' surface diffusion model correspond directly to surface mobility for small-molecule glasses. In the current work, we examine long-chain polymers via two types of systems: polymeric pillars where the cross sections evolve from square to circular, and large particles which sink into polymeric thin films. For the pillars, we use Mullins' model to interpret changes in curvature. It is found that Mullins' decay constants correspond to relaxation times that can be identified with distinct segmental relaxation processes. Such decay constants exhibit a strong dependence on chain length and temperature. For the particle-thin film systems, we relate the rate of particle sinking to various measures of local mobility in the film. This setup is a direct analog to recent experimental work. The results presented here provide a connection between surface shape transformations, mobility, and diffusion.

12:27PM Q50.00007 Shear thinning near the rough boundary in a viscoelastic flow , SAYED HASAN, SERGEI OBUKHOV, Department of Physics, University of Florida — It was first noticed by de Gennes, that because of huge difference between viscosities of entangled polymeric liquid and monomeric liquid, the boundary conditions for a polymer flow near microscopically smooth boundary should be assumed as "slip". Nevertheless, in the presence of surface roughness, or undulations, the flow is characterized by mixed boundary conditions. We had shown that at certain slip velocities the deformation of the melt near the rough (undulated) boundary might become more elastic than viscous. This results in "shear thinning" of the roughness of boundary. At higher velocities, near the slip boundary, the chains can be considered simply trapped in an entangled mesh of other chains. They are subjected to oscillating strain rate, comparable to frequencies of internal Rouse modes of these chains. We calculate the total dissipation of energy due to oscillating strain and calculate the slippage of the polymer melt near the boundary as function of velocity, undulation wavelength and amplitude.

12:39PM Q50.00008 Relaxation of Capillary Wrinkles¹ , KAMIL TOGA, NARAYANAN MENON, THOMAS RUSSELL, University of Massachusetts, Amherst — We have investigated the relaxation of a wrinkle pattern on a thin viscoelastic film. The films are made from spin-coated PS (polystyrene) of thickness ranging from 40 to 240 nm that were floated on the surface of water. Viscoelastic behavior is introduced to the film by depressing the glass transition of PS with a soluble plasticizer, dioctyl phthalate. Wrinkle patterns are formed by placing a small droplet ($\sim 1\mu\text{L}$) at the center of the floating disc. Due to the differential tension generated across the film, radial wrinkles form around the drop where the compressive axial force buckles the membrane. Thereafter, length of the wrinkles decays, and so does their wavelength. We have studied the relaxation of wrinkles as a function of PS molecular weight and plasticizer content, in order to understand the relationship with the bulk glass transition temperature.

12:51PM Q50.00009 New insight into the melting behavior of nanoconfined semicrystalline polymers -The effect of an immobile interfacial layer at the substrate- , MITSUNORI ASADA, Kuraray Co., Ltd., NAISHENG JIANG, PETER GIN, LEVENT SENDOGDULAR, MAYA K. ENDOH, Department of Materials Science and Engineering, Stony Brook University, MORIYA KIKUCHI, Japan Science Technology Agency, ERATO, Takahara Soft Interfaces, ATSUSHI TAKAHARA, Japan Science Technology Agency, ERATO, Takahara Soft Interfaces, Graduate School of Engineering, Kyushu University, TADANORI KOGA, Department of Materials Science and Engineering, Stony Brook University, Chemical and Molecular Engineering Program, Stony Brook University — It is known that when semicrystalline polymer chains are confined on a nanometer length scale, the crystalline structures and dynamics differ from bulks, the so-called "nanoconfinement effects." In this talk, we will report the anomalous melting behavior of nano-confined polyethylene spin cast films prepared on Si substrates by integrating various in-situ grazing incidence scattering techniques. We found that a very thin adsorbed layer at the weakly interactive substrate interface plays a crucial role in the melting behavior.

1:03PM Q50.00010 Solvent Swelling as a Means to Modify the Properties of Polymer Thin Films , ANDREW CLOUGH, OPHELIA TSUI, Boston University, MITHUN CHOWDHURY, KAIWAN JAHANSAHI, GUENTER REITER, Albert-Ludwigs-Universitaet Physikalisches Institut, Freiburg, Germany — It has been observed that sample preparation can influence certain properties of polymer films. In particular, spin-coating from solutions of different solvent qualities result in films with different chain conformations. We surmise that upon formation by spin-coating, the chain conformation of a film is still adjustable by means of solvent swelling, resulting in modifications to the amount of entanglement and free volume. Initial measurements of thermal expansion upon heating after swelling suggest that there is a difference between polystyrene films swelled with a good solvent and a Θ solvent. We have begun a more detailed investigation by studying the effect of swelling on the dewetting behaviors. Preliminary data indicates that the quality of the solvent affects both the dewetting hole size and aging rate of the film.

1:15PM Q50.00011 Equilibration of Polymer Films Cast from Solutions with Different Solvent Qualities, RANXING NANCY LI, ANDREW CLOUGH, DONGDONG PENG, ZHAOHUI YANG, OPHELIA TSUI, Boston University — The preparation history can affect the physical properties of polymer thin films. In spin coating, films are made from a polymer solution. Due to rapid evaporation of solvent in this process, the polymer chains in the films cannot fully interpenetrate, resulting in a non-equilibrium conformation with reduced entanglement density. These in turn can affect the film's equilibration process and viscoelastic properties. On the basis that the chain conformation and entanglement density in a film depend on the conformation of the chains while in solution before spin-coating. We modify the structural properties of the films by adjusting the quality of the solvent used in spin-coating. We examine in detail how these adjustments affect the way polystyrene films approach equilibrium on annealing above the glass transition temperature. It is found that the equilibration time of the film is significantly increased as the solvent quality is decreased towards the Θ condition. We attribute this observation to reduced entanglement in the films with decreasing solvent quality.

1:27PM Q50.00012 Tuning confinement effects at constant film thickness, SIMONE NAPOLITANO, Universite Libre de Bruxelles — We show experimental evidence confuting the commonly accepted idea that the deviation from bulk behavior can be explained in terms of finite size effects and interfacial interactions. By reproducing Guiselin's experiment and upon variation of the molecular weight, we could prepare films of polystyrene spincoated on aluminum and annealed for the same time, having constant thickness but different glass transition temperature and tracer diffusivity. The results can be rationalized in terms of t^* , a dimensionless parameter obtained by the ratio of the annealing time and the adsorption time [1], quantifying the equilibrium character of the films. Further evidence on the relevance of t^* on understanding the behavior of polymers at the nanoscale is provided [2].

1:39PM Q50.00013 Capillary levelling in thin polymer films as a nano-rheological tool to probe interface dynamics, JOSHUA MCGRAW, OLIVER BAEUMCHEN, MELISSA FERRARI, PAUL FOWLER, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — Entanglement of polymer chains in confinement is modified as a result of altered chain conformations. According to Silberberg's principle, chain segments are reflected at an interface causing a reduction of the inter-chain entanglement density. If the interface is transient, local polymer conformation changes can be inferred from a temporal change in flow properties: over time polymer chains become more entangled, thus there is more resistance to flow. Here, we measure the gradual disappearance of an entropic interface between two melts of identical polymer chains during the flow of stepped bilayer polymer films. Samples are prepared in the glassy state and, when in the melt, flow to relieve the Laplace pressure gradient induced by a step in the topography (McGraw *et al.*, Soft Matter, 2011). Our results reveal the dynamics of re-entanglement across the transient entropic interface.

1:51PM Q50.00014 Slow physical aging of thin polymer films of varying chain architecture¹, BRADLEY FRIEBERG, EMMANUIL GLYNOS, PETER GREEN, University of Michigan — The physical aging rate of supported polystyrene (PS) films is influenced by film thickness, H , and by macromolecular architecture. For linear PS films, in the thickness range 300 nm to 50 nm, supported by silicon oxide substrates, the aging rate decreased by 15 percent. On the other hand, star-shaped PS, with functionality $f=8$ and with an average molecular weight per arm of $M_{arm}=25$ kg/mol, exhibited a 25 percent decrease throughout the same thickness range. When M_{arm} was decreased to 10 kg/mol the depression in aging rate was 45 percent. We reconcile these changes in physical aging in terms of model that accounts for gradients in the local T_g of the film in the vicinity of interfaces. These findings have important implications for the processing and function of thin polymer films for different applications.

¹Support for this research from the National Science Foundation (NSF), Division of Material Research, Polymer Program No. 0906425 is gratefully acknowledged.

2:03PM Q50.00015 Diffusion of adsorbed theta-solvent polymers at a solid-liquid interface, CHANGQIAN YU, SUNG CHUL BAE, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, UNIVERSITY OF ILLINOIS AT URBANA-CHAMPAIGN TEAM — We study how surface diffusion depends on temperature when this is varied below the theta temperature. In the polystyrene-cyclohexane system, we use FRAP (fluorescence recovery after photobleaching) to measure over times over 4 orders of magnitude, from 10 sec to 10^5 seconds. A fast component of motion is attributed to chains loosely bound to the surface. A slower component of motion is retained after rinsing; it is subdiffusive. At temperatures below the bulk coexistence temperature, the surface layer is thicker than a monolayer. We show that bulk phase separation of polymers in dilute solution produces a dense surface layer of emulsion and foamy near-surface structure.

Session Q51 DCMP DFD: Gels, Complex Fluids and Vesicles Boston Convention Center 154

11:15AM Q51.00001 Linear Viscoelasticity and Swelling of Polyelectrolyte Complex Coacervates, FAWZI HAMAD, RALPH COLBY, Pennsylvania State University — The addition of near equimolar amounts of poly(diallyldimethylammonium chloride) to poly(isobutylene-alt-maleate sodium), results in formation of a polyelectrolyte complex coacervate. Zeta-potential titrations conclude that these PE-complexes are nearly charge-neutral. Swelling and rheological properties are studied at different salt concentrations in the surrounding solution. The enhanced swelling observed at high salt concentration suggests the system behaves like a polyampholyte gel, and weaker swelling at very low salt concentrations implies polyelectrolyte gel behavior. Linear viscoelastic oscillatory shear measurements indicate that the coacervates are viscoelastic liquids and that increasing ionic strength of the medium weakens the electrostatic interactions between charged units, lowering the relaxation time and viscosity. We use the time-salt superposition idea recently proposed by Spruijt, et al., allowing us to construct master curves for these soft materials. Similar swelling properties observed when varying molecular weights. Rheological measurements reveal that PE-complexes with increasing molecular weight polyelectrolytes form a network with higher crosslink density, suggesting time-molecular weight superposition idea.

11:27AM Q51.00002 Multicomponent effects in diffusion within microemulsions, WYATT MUSNICKI, STEPHANIE DUNGAN, RONALD PHILLIPS, University of California Davis, CHEMICAL ENGINEERING AND MATERIAL SCIENCE DEPARTMENT TEAM — Holographic interferometry was used to monitor transport of hydrophobic solutes in systems containing nanometer-scale microemulsion droplets. In this technique, variations in the refractive index between a reference time and a later time are monitored via interference fringes that are formed with the help of a holographic plate. The refractive index change is driven by imposed concentration differences of either the solute (at constant surfactant concentration), or of the surfactant (at constant solute concentration). We find that, especially for hydrophobic solutes, the transport kinetics cannot be interpreted by using a pseudobinary approximation. Multicomponent interaction effects must be taken into account even at micelle concentrations as low as 6%. By performing multiple experiments with different initial concentration gradients, and extending earlier analyses of the experimental interference fringes, the multicomponent effects can be resolved, yielding results for all the relevant diffusion coefficients.

11:39AM Q51.00003 Determining the structure and properties of complex coacervate crosslinked triblock copolymer hydrogels, DANIEL KROGSTAD, SOO-HYUNG CHOI, JASON SPRUELL, NATHANIEL LYND, EDWARD KRAMER, Materials Research Laboratory, University of California at Santa Barbara, MATTHEW TIRRELL, Institute for Molecular Engineering, University of Chicago — The mechanical properties and structures of functionalized P(AGE-b-EO-b-AGE) hydrogels utilizing complex coacervation as a physical crosslink have been studied. The effects of variables such as polymer concentration, salt concentration, pH, stoichiometric ratios and temperature have been investigated by rheology and SAXS. It was found that the organization of the cores has a very strong effect on the mechanical properties. This can be observed as the storage modulus increases significantly between 15 and 16 wt% corresponding to a transition from a disordered gel to a BCC structure. Another dramatic change is observed when the storage modulus drops between 25 and 30 wt% as the hexagonal structure becomes predominant. Just as polymer concentration causes changes in structure and thus the properties, salt concentration has a similar effect due to the electrostatic nature of the hydrogels. As salt is added, the electrostatic interactions in the cores are screened until they are weak enough that the polymers are dissolved into the matrix. The mechanical properties and the physical nature of the crosslinks lead to the possibility of these gels being used as an injectable drug delivery system.

11:51AM Q51.00004 Density mode microrheology in polyacrylamide gels, BEATRIZ BURROLA GABILONDO, DANIEL SISAN, Georgetown University, JONATHAN LANDY, ALEX LEVINE, University of California, Los Angeles, JEFFREY URBACH, Georgetown University — In passive microrheology the viscoelastic properties of soft materials are deduced by observing thermal fluctuations of tracer particles embedded within the material, and the response function obtained from the spectrum of thermally excited modes is then related to the viscoelastic shear modulus. This approach is valid for single-component, isotropic, incompressible materials. However, for heterogeneous materials, such as hydrogels, a more comprehensive approach is needed. We measure the equilibrium density fluctuations of a cross-linked polymer gel swollen in a solvent and compare them to the predictions of the 'two-fluid' model of the dynamics of polymer gels. We will describe a direct method of extracting the longitudinal response function of a soft material based on the temporal and spatial correlations of density fluctuations of fluorescent markers, called density mode microrheology (DMM). We will also present results of applying DMM to fluorescent polyacrylamide gels in an aqueous solvent of varying viscosity and comparing them with parameters obtained from conventional microrheology.

12:03PM Q51.00005 Effect of Polymer Molecular Weight and Synthesis Temperature on Structure and Dynamics of Microgels¹, KRISTA G. FREEMAN, KIRIL A. STRELETZKY, Cleveland State University — Environmentally-sensitive microgels have been synthesized under varying conditions to study the dependences on polymer molecular weight (M_W) and synthesis temperature (T_{syn}). The dynamics and structure of the synthesized microgels below and above the LCST of the polymer ($T_c \sim 41^\circ\text{C}$) were studied using dynamic and static light scattering spectroscopy. All microgels exhibit a volume phase transition above the LCST of the polymer and undergo a reversible 15-50-fold volume shrinkage. The size distribution, structure, deswelling ability, and temperature response of microgels strongly depend on synthesis conditions. T_{syn} dependence was studied with 1000kDa polymer. Increasing $\Delta T = T_{syn} - T_c$ yields smaller microgels with a smaller swelling ratio up to $\Delta T = 8.5^\circ\text{C}$, after which the trend is reversed. The amphiphilic nature of the polymer may explain this trend. T_{syn} also affects the structure of microgels; low T_{syn} yields elongated particles, while high T_{syn} microgels are more spherical. Polymer M_W directly effects microgel polydispersity and temperature response. While microgels synthesized with 1000kDa polymer are relatively monodisperse, synthesis with low M_W polymers (80-370kDa) yields systems with a large population ($R_h \sim 1000\text{nm}$) precipitating out of solution and a smaller population ($R_h \sim 300\text{nm}$) staying in suspension. M_W also influences the temperature response of microgels; high M_W microgels show a gradual shrinkage with increasing temperature while low M_W microgels display a delayed and sudden shrinkage at high temperatures.

12:15PM Q51.00006 Gelation and state diagram for a model nanoparticle system with adhesive hard sphere interactions, NORMAN WAGNER, University of Delaware, EBERLE AARON, NIST — We provide the first comprehensive state diagram of thermoreversible gelation in a model nanoparticle system from dilute concentrations to the attractive driven glass. We show the temperature dependence of the interparticle potential is related to a surface molecular phase transition of the brush layer using neutron reflectivity (NR) and small-angle neutron scattering (SANS) [1]. We establish the temperature dependence of the interparticle potential using SANS, dynamic light scattering (DLS), and rheology. The potential parameters extracted from SANS suggest that, for this system, gelation is an extension of the Mode Coupling Theory (MCT) attractive driven glass line (ADG) to lower volume fractions and follows the percolation transition. Below the critical concentration, gelation proceeds without competition for phase separation [2]. These results are used to develop a complete state diagram for the sticky hard sphere reference system.

12:27PM Q51.00007 Hydrodynamics and Rheology of Active Liquid Crystals, ZHENLU CUI, Fayetteville State University — Active liquid crystals such as swimming bacteria, active gels and assemblies of motors and filaments are active complex fluids. Such systems differ from their passive counterparts in that particles absorb energy and generate motion. They are interesting from a more fundamental perspective as their dynamic phenomenons are both physically fascinating and potentially of great biological significance. In this talk, I will present a continuum model for active liquid crystals and analyze the behavior of a suspension subjected to a weak Poiseuille flow. Hydrodynamics, stability and rheology will also be discussed.

12:39PM Q51.00008 Electrostatics-driven assembly of uni-lamellar catanionic faceted vesicles, CHEUK-YUI LEUNG, LIAM PALMER, SUMIT KEWALRAMANI, RASTKO SKNEPNEK, GRAZIANO VERNIZZI, MEGAN GREENFIELD, SAMUEL STUPP, MICHAEL BEDZYK, MONICA OLVERA DE LA CRUZ, Northwestern University — Nature utilizes shape to generate function. Organelle and halophilic bacteria wall envelopes, for example, adopt various polyhedral shapes to compartmentalize matter. The origin of these shapes is unknown. A large variety of shell geometries, either fully faceted polyhedra or mixed Janus-like vesicles with faceted and curved domains that resemble cellular shells can be generated by coassembling water-insoluble anionic (−1) amphiphiles with high valence cationic (+2 and +3) amphiphiles. Electron microscopy, X-ray scattering, theory and simulations demonstrate that the resulting faceted ionic shells are crystalline, and stable at high salt concentrations. The crystallization of the co-assembled single tail amphiphiles is induced by ionic correlations, and modified by the solution pH. This work promotes the design of faceted shapes for various applications and improves our understanding of the origin of polyhedral shells in nature.

12:51PM Q51.00009 Modeling controlled release from responsive microgel capsules¹, ALEXANDER ALEXEEV, HASSAN MASOUD, Georgia Institute of Technology, George W. Woodruff School of Mechanical Engineering — We introduce a coarse-grained computational method that explicitly captures the release of nanoparticles and macromolecules from responsive microgel capsules. The model is based on the dissipative particle dynamics. Our simulations reveal that not only swelling, but also deswelling of hollow microcapsules can be harnessed for controlled release. We show that the release from swollen capsules is diffusion driven, whereas the release from deswelling gel capsules occurs due to the flow of encapsulated solvent that is expelled from the shrinking capsule interior. The latter hydrodynamic release is burst-like and continues only during capsule deswelling. We find that deformable polymer chains that can easily penetrate thorough membrane pores are released in larger amounts from deswelling capsules, than nanoparticles that are filtered out by shrinking membrane pores. Our simulations further demonstrate that the inclusion of rigid microrods inside deswelling capsules mitigates the membrane pore closing, and, in this fashion, provides an effective method for regulating the rate of hydrodynamic release of nanoparticles.

1:03PM Q51.00010 Thermoresponsive microcapsules for controlled release of hydrophilic cargo, ESTHER AMSTAD, DAVID WEITZ, Harvard University — Thermoresponsive microcapsules that collapse upon increasing the temperature above their lower critical solution temperature (LCST) such as poly(N-isopropyl acrylamide) (PNIPAM) capsules are well known. However, capsules consisting of thermoresponsive polymers that possess an upper critical solution temperature (UCST) and therefore swell upon increasing the temperature above their UCST are scarce. We will present a microfluidic method to assemble thermoresponsive poly([2-(methacryloyloxy)-ethyl]-dimethyl-[3-sulfopropyl-ammoniumhydroxide]) (PMEDSH) microcapsules that have UCST. These capsules are in a collapsed state at room temperature and become highly water permeable upon increasing the temperature above the UCST. To simultaneously allow for encapsulation of hydrophilic cargo and enable the water based polymerization reaction of the PMEDSH shell, these microcapsules are assembled as water/water/oil emulsions using capillary microfluidic devices. The resulting PMEDSH microcapsules are envisaged as delivery vehicles and microreactors that allow for temperature induced controlled release of hydrophilic cargo. .

1:15PM Q51.00011 A Nano Engineered Membrane for Oil-Water Separation, BRIAN SOLOMON, NASIM HYDER, KRIPA VARANASI, Massachusetts Institute of Technology, VARANASI RESEARCH GROUP TEAM — Oil and water separation is an extremely costly problem in the petroleum industry. Pumping the complete emulsion to the surface requires substantially more power than pumping the oil alone. A membrane that can efficiently separate oil from water at the source would revolutionize this process. To this end a novel, layered, hierarchical thermoplastic membrane was fabricated with both nanoscale and microscale features. Modifying the length scales involved in fabrication of the membrane yields interesting and non-obvious implications. Under certain regimes, the microscale features independently control the membrane's permeability, while the microscale features control only the membrane's breakthrough pressure. By operating in this regime, separation efficiencies can be realized that are otherwise unattainable by conventional membranes. Taking it a step further, chemical treatments have been used to achieve higher hydrophobicity for the membrane by lowering the surface energy of the membrane surface. Although this research focused on oil-water separation, the results have implications for other multiphase systems and hold for many other filtration and separation technologies including in lab-on-chip devices and micro/nanofluidic devices.

1:27PM Q51.00012 Tether formation on a settling vesicle, GWENN BOEDEC, M2P2 UMR 6181 CNRS Aix Marseille University, MARC JAEGER, M2P2 UMR 6181 CNRS Aix Marseille University - Centrale Marseille, MARC LEONETTI, IRPHE UMR 6594 CNRS Aix Marseille University — When submitted to a point-like force, a phospholipid vesicle (a lipid membrane enclosing a drop) is known to develop a narrow tether. This tether formation is reminiscent of drop pinch-off, but the peculiar properties of the vesicle interface prevents the apparition of a finite-time singularity. It is shown that a settling vesicle may develop such tethered shapes, with hydrodynamic stresses acting as the pulling force. These shapes are studied numerically and theoretically, and continuous families of stationary tethered shapes are found, depending on two control parameters. Dynamics of formation is studied and it is shown that changing the initial condition can lead to complex transients, with formation of pearls onto the tether.

1:39PM Q51.00013 Electrohydrodynamic instabilities of biomimetic bilayer membranes, JACOPO SEIWERT, PETIA VLAHOVSKA, Brown university — Living cells actively maintain electrochemical potentials across their membranes, which regulates cell migration, motility, and development. In this presentation, we focus on the effect of an external electric field on membrane dynamics. We present a physical model for the dynamic coupling between transmembrane potential and deformation of biomimetic membranes. We perform linear stability analysis to clarify and quantify the effects of the lipid bilayer properties (conductivity and capacitance), and asymmetry in the embedding electrolyte solutions, on membrane deformation.

1:51PM Q51.00014 Polyoxometalate (POM) Nanocluster-Induced Phase Transition and Structural Disruption in Lipid Bilayers., BENXIN JING, Y. ELAINE ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame, Notre Dame, Indiana 46556, United States, MARIE HUTIN, LEROY CRONIN, School of Chemistry, University of Glasgow, Glasgow G12 8QQ, United Kingdom, CRONIN GROUP OF COMPLEX CHEMICAL SYSTEM COLLABORATION — Polyoxometalate (POM) nanoclusters that are transition metal oxygen clusters with well defined atomic coordination structures have recently emerged as new and functional nanocolloidal materials used as catalysts, anti-cancer medicines, and building blocks for novel functional materials. However, their implications to human health and environment remain poorly investigated. In this work, we examine the interaction of highly charged anionic POM nanoclusters with lipid bilayers as a model cell membrane system. It is observed that upon the adsorption of anionic POMs, lipid dynamics is significantly suppressed and lipid bilayers are disrupted with resultant pore and budding-like structural formation. Direct calorimetric experiment of POM interaction with lipid bilayers of varied lipid compositions confirms the POM-induced fluid-to-gel phase transition in lipid bilayers, due to strong electrostatic interaction between POM nanocluster and lipid head groups.

2:03PM Q51.00015 Liquid-to-solid transition in suspensions of swollen microgels, JUAN JOSE LIETOR-SANTOS, ALBERTO FERNANDEZ-NIEVES, BENJAMIN SIERRA-MARTIN, Georgia Tech — We investigate the phase and non-equilibrium behavior of suspensions comprised of swollen, ionic microgels as a function of particle stiffness. We find that stiff particles exhibit all three phases observed in hard sphere suspensions, liquid, crystal and glass. For particles with intermediate stiffness, the crystal phase disappears and the microgel suspension transitions from a liquid to a glassy state at certain particle concentration. For even softer particles, no glassy state is observed. Instead the system remains liquid within the experimentally accessed concentration range. Interestingly, for microgels with intermediate stiffness, we find that the bulk modulus of individual particles seems to control the mechanical properties of the microgel suspension in the overpacked regime, emphasizing the relevance of being compressible.

Wednesday, February 29, 2012 11:15AM - 2:15PM –
Session Q52 GSNP DFD: Focus Session: Extreme Mechanics - Shells & Snapping 153C

11:15AM Q52.00001 Mechanics and Dynamics of a Snapping Arch , DOUGLAS HOLMES, Virginia Tech, MATTHIEU ROCHÉ, TARUN SINHA, HOWARD STONE, Princeton University — Snap-buckling of geometric arches and thin spherical shells occur in a variety of different geometric situations, exhibiting a highly nonlinear response dictated by the geometry and material properties of the system. As this elastic instability often precedes the catastrophic failure of a mechanical system, significant work has focused on the stability criteria for such structures. In order to properly understand the biomechanics of plants that rely on this instability, and in addition use snap-buckling in the design of advanced materials, it is necessary to also develop a fundamental understanding of the timescale and post-buckling response of a snapping structure. Currently, a fundamental understanding of the osmotically-induced snap-buckling phenomena is lacking. In this presentation, we examine the osmotic swelling of a bistable arch to identify the stability criteria, relevant snap-through timescale, and the impact of geometric confinement on snap-through symmetry and damping.

11:27AM Q52.00002 Elastocapillary-driven snap-through instability , AURELIE FARGETTE, ARNAUD AN-TKOWIAK, SEBASTIEN NEUKIRCH, Institut Jean le Rond d'Alembert, UPMC — The snap-through instability, which is present in a wide range of systems ranging from carnivorous plants to MEMS, is a well-known phenomenon in solid mechanics : when a buckled elastic beam is subjected to a transverse force, above a critical load value the buckling mode is switched. Here, we revisit this phenomenon by studying snap-through under capillary forces. In our experiment, a droplet (which replaces the usual dry load) is deposited on a buckled thin strip, clamped horizontally at both ends. In this setup both the weight of the drop and capillary forces jointly act toward the instability. The possibility of reverse elastocapillary snap-through, where the droplet is put under the beam, is then tested and successfully observed, showing the predominance of capillary forces at small enough scales.

11:39AM Q52.00003 Fast Motion of Plants through mechanical instability: Mechanics without Muscles¹ , QIAOHANG GUO², College of Materials Science and Engineering, Fuzhou University; Fujian University of Technology, Fuzhou, China, ZI CHEN, Biomedical Engineering, Washington University in St. Louis, HUANG ZHENG, Fujian Radio and Television University, Fuzhou, China, WENZHE CHEN, Fuzhou University, Fujian University of Technology, Fuzhou, China — Plants are not well known for fast motions, yet some plants such as the Venus flytrap can move in a fraction of a second to capture insects, even though they do not have nerves or muscles. This type of rapid motion has intrigued scientists for centuries. Darwin did a first systematic study on the trap closure mechanism, and considered the plant as “one of the most wonderful in the world”. Thereafter, several physical mechanisms have been proposed, such as the rapid loss of turgor pressure, an irreversible acid-induced wall loosening mechanism, and the snap-through model by mechanical instability, but with no unanimous agreement among researchers. Here we propose a coupled mechanical bistable mechanism that explains the rapid closure of the Venus flytrap in a comprehensive manner, consistent with a series of experimental observations. Such bistable behaviors are theoretically modeled and validated with table-top experiments. Based on the principles learnt from the Venus flytrap, we are also able to manufacture a preliminary “flytrap robot”. Hence, it is promising to design smart bio-mimetic materials and devices with snapping mechanisms as sensors, actuators, artificial muscles and biomedical devices.

11:51AM Q52.00004 Strange instabilities of simple elastic structures , DAVIDE BIGONI, DIEGO MISSERONI, University of Trento, Trento, Italy, GIOVANNI NOSELLI, Cambridge University, UK, DANIELE ZACCARIA, University of Trieste, Trieste, Italy — A class of simple elastic structures is shown exhibiting bifurcation and instability under tensile dead loading, multiple bifurcations, and softening/hardening behaviour in the postcritical regime. These structures evidences new and unexpected behaviours which are theoretically predicted and experimentally verified. These nonlinear behaviours can be exploited in the design of flexible mechanics devices and open new perspective in the control of vibrations.

12:03PM Q52.00005 Materials with Tunable Behavior due to Constrained Instabilities: Performance and Stability Analysis , DENNIS KOCHMANN, California Institute of Technology, WALTER J. DRUGAN, University of Wisconsin-Madison — Combining several materials into a composite permits the creation of new materials with overall properties tunable via a careful choice of the constituent materials with favorable specifics. The probably simplest example is a particle-matrix system, in which particles of one material enhance the mechanical behavior of the matrix material. Recent advances have confirmed that the overall performance of such a composite (e.g., its viscoelastic properties) can be dramatically altered, and stiffness and damping can be tuned to an extreme if one allows for temporarily negative elastic moduli in the inclusion. Such incremental negative moduli imply instability; e.g. a free-standing body of negative stiffness is thermodynamically unstable. However, through its geometric constraint a matrix phase can stabilize the otherwise unstable state of the inclusion phase, thus rendering the overall composite stable. In this contribution, we show, based on dynamic stability analyses, that the matrix constraint does indeed allow for the existence and use of negative moduli, and that this effect can be utilized to design novel composites of superior performance. Approaches to stabilize the negative-stiffness effect will be discussed as well as the performance of such composites.

12:15PM Q52.00006 Snap-Through of Graphene: An Elasto-Capillary Perspective , TILL WAGNER, DAMTP, University of Cambridge, DOMINIC VELLA, OCCAM, University of Oxford — Understanding the interaction between graphene flakes and various substrates is of crucial importance for nanoelectromechanical systems (NEMS) applications, among others. The ‘snap-through’ instability of graphene flakes placed onto corrugated substrates has recently received much attention as a potential assay for the study of this interaction. A sharp transition has been found in the morphology of the graphene between a) closely adhering to the corrugations of the substrate and b) lying almost completely flat on top. Which of these morphologies is observed depends on the geometry of the substrate and the mechanical properties of the flake. In this talk we shall focus on understanding the nature of this transition and, in particular, the ‘sharpness’ of the transition. We investigate how the location of snap through and its sharpness might be used to yield estimates of adhesion strength and friction with the substrate.

12:27PM Q52.00007 Electromechanical phase transition in dielectric elastomers under uniaxial tension and electrical voltage , RUI HUANG, University of Texas at Austin, ZHIGANG SUO, Harvard University — Subject to forces and voltage, a dielectric elastomer may undergo electromechanical phase transition. A phase diagram is constructed for an ideal dielectric elastomer membrane under uniaxial force and voltage, reminiscent of the phase diagram for liquid-vapor transition of a pure substance. We identify a critical point for the electromechanical phase transition. Two states of deformation (thick and thin) may coexist during the phase transition, with the mismatch in lateral stretch accommodated by wrinkling of the membrane in the thin state. The processes of electromechanical phase transition under various conditions are discussed. A reversible cycle is suggested for electromechanical energy conversion using the dielectric elastomer membrane, analogous to the classical Carnot cycle for a heat engine. The amount of energy conversion, however, is limited by failure of the dielectric elastomer due to electrical breakdown. With a particular combination of material properties, the electromechanical energy conversion can be significantly extended by taking advantage of the phase transition without electrical breakdown.

12:39PM Q52.00008 Soft Dielectrics: Heterogeneity and Instabilities, STEPHAN RUDYKH, GAL DEBOTTON, Ben-Gurion University of the Negev, KAUSHIK BHATTACHARYA, California Institute of Technology — Dielectric Elastomers are capable of large deformations in response to electrical stimuli. Heterogeneous soft dielectrics with proper microstructures demonstrate much stronger electromechanical coupling than their homogeneous constituents. In turn, the heterogeneity is an origin for instability developments leading to drastic change in the composite microstructure. In this talk, the electromechanical instabilities are considered. Stability of anisotropic soft dielectrics is analyzed. Ways to achieve giant deformations and manipulating extreme material properties are discussed. 1. S. 12:51PM Q52.00009 Modeling of dielectric elastomeric materials: theory, finite element simulation, and applications, DAVID HENANN, KATIA BERTOLDI, School of Engineering and Applied Science, Harvard University — Elastomeric materials that undergo large deformations in response to an electric field have garnered attention in recent years. Applications of these dielectric elastomeric materials include actuators capable of converting electrical energy to mechanical work and energy harvesting devices that convert mechanical energy into electrical energy. Furthermore, dielectric elastomers exhibit interesting instabilities, especially under constrained geometries, opening the door for possible applications in active surfaces. Interest has increased in the mechanics community concerning the formulation of a finite-deformation constitutive theory for an electro-mechanically-coupled material. While the details of the formulation of such a theory are beginning to come into focus in the literature, numerical techniques for solving these equations are in their infancy. In this work, we have developed a finite-element-based numerical simulation capability for dielectric elastomers. This talk will highlight the application of our numerical simulation capability to dielectric elastomeric actuators, energy harvesting devices, as well as instabilities of small dielectric elastomeric structures on a constraining substrate.

1:03PM Q52.00010 Giant linear voltage-induced deformation of a dielectric elastomer actuator, JIAN ZHU, School of Engineering and Applied Sciences, Harvard University, MATTHIAS KOLLOSCH, GUGGI KOFOD, University of Potsdam, Germany, ZHIGANG SUO, School of Engineering and Applied Sciences, Harvard University — For dielectric elastomers, one of the most conspicuous attributes is large deformation of actuation induced by voltage. However, electromechanical instability may limit their deformation. In this seminar, I will illustrate how dielectric elastomers survive or eliminate electromechanical instability, through mechanical designs. For example, I will analyze a dielectric elastomer with a "pure shear" boundary condition. The membrane is first prestretched along the transverse direction, and then fixed by a rigid bar. As a result, the stretch in transverse direction is fixed, and the membrane can only be actuated along the vertical direction. The theory shows that the actuator can avert electromechanical instability, and achieve a giant linear deformation of actuation. The experiments confirm the theoretical predictions. For SEBS material, the linear strain of actuation can be 80%. For VHB material, the linear strain of actuation can be 300%. The actuator shows advantages compared to the classic designs (say, tube and circular actuators), and can be used as artificial muscles in soft robots.

1:15PM Q52.00011 Geometry-induced rigidity in pressurized elastic shells, PEDRO REIS, Massachusetts Institute of Technology, BASTIAAN FLORIJN, MIT and Leiden University, ARNAUD LAZARUS, MIT — We study the indentation of pressurized thin elastic shells, with positive Gauss curvature. In our precision desktop-scale experiments, the geometry of the shells and their material properties are custom-controlled using rapid prototyping and digital fabrication techniques. The mechanical response is quantified through load-displacement compression tests and the differential pressure is set by a syringe-pump system under feedback control. Focus is given to the linear regime of the response towards quantifying the geometry-induced rigidity of pressurized shells with different shapes. We find that this effective stiffness is proportional to the local mean curvature in the neighborhood of the locus of indentation. Combining classic theory of shells with recent developments by D. Vella et al. (2011), we rationalize the dependence of the geometry-induced rigidity on: i) the mean curvature at the point of indentation, ii) the material properties of the shell and iii) the in-out differential pressure. The proposed predictive framework is in excellent agreement with our experiments, over a wide range of control parameters. The prominence of geometry in this class of problems points to the relevance and applicability of our results over a wide range of lengthscales.

1:27PM Q52.00012 S-cones in thin shells under indentation, ALICE NASTO, Massachusetts Institute of Technology, AMIN AJDARI, Northeastern University, ARNAUD LAZARUS, MIT, ASHKAN VAZIRI, Northeastern University, PEDRO REIS, MIT — We perform a hybrid experimental and numerical investigation of the localization of deformation in indented thin spherical elastic shells. Past the initial linear response, an inverted cap develops as a Pogorelov circular ridge. For further indentation, this ridge loses axis-symmetry and sharp points of localized curvature form. We refer to these localized objects as *s-cones* (for shell-cones), in contrast with their developable cousins in plates (*d-cones*). We quantify the effect of systematically varying the indenter's radius of curvature (from point to plate load) on the formation and evolution of *s-cones*. In our precision desktop-scale experiments we use rapid prototyped elastomeric shells and rigid indenters of various shape. The mechanical response is measured through load-displacement compression tests and the deformation process is further characterized through digital imaging. In parallel, the experimental results are contrasted against nonlinear Finite Element simulations. Merging these two complementary approaches allows us to gain further physical insight towards rationalizing this geometrically nonlinear process.

1:39PM Q52.00013 Folding and buckling pathways in spherical shells with soft spots, JAYSON PAULOSE, Harvard School of Engineering and Applied Sciences, Cambridge, MA 02138, DAVID NELSON, Department of Physics, Harvard University, Cambridge, MA 02138 — Thin elastic spherical shells subject to an external pressure undergo a buckling transition when the pressure reaches a critical value. Past the buckling instability, the shell typically takes on a shape with one or more inversions that focus the elastic deformation energy within narrow circular regions on the sphere. These inversions are associated with large volume changes and hysteresis, and their location is highly sensitive to very slight imperfections in the sphere. Recently, it has been demonstrated [1] that natural pollen grains have evolved soft sectors in their hard outer walls which guide them toward particular folding pathways when their internal volume is reduced due to desiccation, thus avoiding sudden and uncontrolled changes in shape. Motivated by these results, we study the effect of circular soft spots on the buckling of otherwise uniform spherical shells. Through a combination of scaling arguments and numerical simulations, we demonstrate that the shell can be tuned to follow distinct buckling pathways by varying the size and stiffness of the soft spot. [1] E. Katifori et al, *Proc. Natl. Acad. Sci. USA* **107**, 7635 (2010)

1:51PM Q52.00014 Buckliballs: Buckling-Induced Pattern Transformation of Structured Elastic Shells, KATIA BERTOLDI, JONGMIN SHIM, SEAS, Harvard Univ, CLAUDE J. PERDIGOU, MIT, ELIZABETH R. CHEN, University of Michigan at Ann Arbor, PEDRO M. REIS, MIT — We present a class of continuum shell structures, the buckliball, which, undergo a structural transformation induced by buckling under pressure loading. The geometry of the buckliball comprises a spherical shell patterned with a regular array of circular voids. Moreover, we show that the buckling-induced pattern transformation is possible only with five specific hole arrangements. These voids are covered with a thin membrane, thereby making the ball air tight. Beyond a critical internal pressure, the thin ligaments between the voids buckle leading to a cooperative buckling cascade of the skeleton of the ball. Both precision desktop-scale experiments and finite element simulations are used to explore the underlying mechanics in detail and proof of concept of the proposed structures. We find excellent qualitative and quantitative agreement between experiments and simulations. This pattern transformation induced by a mechanical instability opens the possibility for reversible encapsulation, over a wide range of length scales.

2:03PM Q52.00015 Wrinkling of a collapsing viscous bubble, JAMES BIRD, Boston University, HOWARD STONE, Princeton University, JOHN BUSH, Massachusetts Institute of Technology — Thin-sheets of sufficiently viscous liquid can behave similar to elastic sheets and buckle under certain external forces. A classic example is the “parachute instability” for which a ruptured viscous bubble wrinkles as it relaxes, with the explanation for the wrinkles being based on the liquid film falling under its own weight. In this talk we revisit the viscous bubble-bursting experiments and demonstrate that gravity is responsible for neither the collapse nor the resulting wrinkling instability. Using a combination of experiments and theory, we highlight the importance of capillary forces and elucidate their role in the wrinkling instability.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q53 DCMP: Packing, Self-Assembly, and Granular Memory 153B

11:15AM Q53.00001 Cooperative effects in DNA nanotile attachment, CORINNA MAASS, LANG FENG, TONG WANG, RUOJIE SHA, NADRIAN SEEMAN, PAUL CHAIKIN, NYU — In the context of realising a DNA nanotile system capable of exponentially replicating an information string encoded in a tile pattern with the aid of thermal and UV cycling [1], we encountered the problem of predicting the hybridisation transition temperatures of DNA tile pairs with multiple single strand connectors (sticky ends). For the common single-helix hybridisation transition, sufficiently accurate predictions can be derived from SantaLucia’s nearest-neighbour parameter analysis [2]. However, the case of several DNA strands hybridising cooperatively while attached to a rigid object is entropically different and we had to develop a method to factor in the resulting phase space restrictions (cf. a similar approach for DNA-covered colloids [3]). We were able to test our thermodynamic model by fluorescently labelling DNA tile pairs with variable numbers of sticky ends and recording the hybridisation transition using FRET. The data fit our prediction within an acceptable parameter range.

11:27AM Q53.00002 Minimal energy packings of weakly semiflexible polymers: Application to targeted self-assembly of nanostructures¹, JARED HARWAYNE-GIDANSKY, Electrical Engineering and Integrated Graduate Program in Physical and Engineering Biology, Yale University, ROBERT S. HOY, COREY S. O’HERN, Mechanical Engineering & Materials Science, and Physics, Yale University — Using exact enumeration, we characterize how structure, mechanical and thermodynamic stability of minimal energy packings of short “sticky tangent sphere” (SHS) polymer chains vary with angular interaction strength k_b and equilibrium bond angle θ_0 . While flexible SHS polymers possess highly degenerate ground states (i. e. many differently ordered “macrostates” [1]), angular interactions dramatically break this degeneracy. The macrostate associated with the ground state semiflexible packing changes as k_b and θ_0 are varied. Further degeneracy breaking arises from angular interactions’ influence on packing size, asymmetry, and vibrational entropy. The strength of these effects increases with chain length N . Our exact analysis provides design principles for self-assembly of polymers into a variety of structures that can be tuned by varying N , k_b and θ_0 .

11:39AM Q53.00003 Self-assembly of Low-coordinated Ground States via Monotonic Pair Potentials, ETIENNE MARCOTTE, FRANK H. STILLINGER, SALVATORE TORQUATO, Princeton University — Monotonically decreasing radially symmetric pair potentials can lead to the self assembly of unusual low-coordinated ground states. The states include, but are not limited to, the square, honeycomb, and simple cubic crystals in two and three-dimensional Euclidean spaces R^2 and R^3 . We can determine optimal potentials for targeted ground states using inverse statistical mechanical techniques. Using a linear programming method, we are able to search over a wide parameter space while still enforcing constraints such as monotonicity and convexity on optimized potentials. The features present in the classes of short-ranged potentials that conform to these constraints suggest sufficient requirements for colloids to self assemble into a desired ground state.

11:51AM Q53.00004 Dense packings of spheres in cylinders, ADIL MUGHAL, Aberystwyth University, HO-KEI CHAN, DENIS WEAIRE, STEFAN HUTZLER, AARON MEAGHER, Trinity College Dublin — We develop a simple analytical theory that relates dense hard sphere packings in a cylinder to corresponding disk packings on its surface. It applies for ratios $R=D/d$ (where d and D are the diameters of the hard spheres and the bounding cylinder, respectively) up to $R=2.738$. Within this range the densest packings are such that all spheres are in contact with the cylindrical boundary. The detailed results elucidate extensive numerical simulations by others and ourselves by identifying the nature of various competing phases. We also present results for the regime R greater than 2.738. These preliminary results explore packings that include internal spheres (i.e. spheres that do not contact the cylinder). This is done through a combination of experiments and numerical simulation (simulated annealing). Our experiments involve the packing of monodisperse bubbles in narrow micron-sized capillaries. Such “wet foams” are an excellent model of the hard sphere packing problem and are analyzed by X-ray tomography to provide structural information.

12:03PM Q53.00005 Novel structures from the densest binary sphere packings, ADAM HOPKINS, YANG JIAO, FRANK STILLINGER, SALVATORE TORQUATO, Princeton University — The densest binary sphere packings have historically been very difficult to determine. The only rigorously known packings in the α - x plane of small to large sphere radius ratio α and small sphere relative concentration x are at the Kepler limit $\alpha \rightarrow 1$, where packings are monodisperse. Utilizing an implementation of the Torquato-Jiao linear programming algorithm, we find many distinct families of novel densest binary packings and construct a phase diagram for all known densest packings over the α - x plane. In particular, these families of densest binary packings are examples of complicated, mechanically stable structures that can appear in colloidal systems without any anisotropic or attractive interactions.

12:15PM Q53.00006 Random and ordered phases of off-lattice rhombus tiles¹, STEPHEN WHITELAM, ISAAC TAMBLYN, Molecular Foundry, Lawrence Berkeley National Lab, PETER BETON, JUAN GARRAHAN, School of Physics and Astronomy, University of Nottingham, Nottingham NG7 2RD, UK — We study the covering of the plane by non-overlapping rhombus tiles, a problem well-studied only in the limiting case of dimer coverings of regular lattices. We go beyond this limit by allowing tiles to take any position and orientation on the plane, to be of irregular shape, and to possess different types of attractive interactions. Using extensive numerical simulations we show that at large tile densities there is a phase transition from a fluid of rhombus tiles to a solid packing with broken rotational symmetry. We observe self-assembly of broken-symmetry phases, even at low densities, in the presence of attractive tile-tile interactions. Depending on tile shape and interactions the solid phase can be random, possessing critical orientational fluctuations, or crystalline. Our results suggest strategies for controlling tiling order in experiments involving “molecular rhombi.”

12:27PM Q53.00007 Structure and stability of finite sphere packings via exact enumeration¹,

ROBERT S. HOY, Departments of Mechanical Engineering & Materials Science, and Physics, Yale University, JARED HARWAYNE-GIDANSKY, Department of Electrical Engineering and Integrated Graduate Program in Physical and Engineering Biology, Yale University, COREY S. O'HERN, Departments of Mechanical Engineering & Materials Science, and Physics, Yale University — We analyze the geometric structure and mechanical stability of complete sets of isostatic and hyperstatic sphere packings obtained via exact enumeration techniques. The number of nonisomorphic isostatic packings grows exponentially with the number of spheres N , and the fraction of packings possessing soft modes (for “sticky” spheres with contact attractions) grows faster. The diversity of structure and symmetry increases with N and decreases with the degree of hyperstaticity. We further show that maximally contacting packings are in general neither the densest nor the most symmetric. Our studies of the geometry of complete sets of sphere packings provide a basis for future work on ground and metastable states in systems with hard-core plus short-range attractive interactions including attractive colloids, collapsed proteins, and jammed particulate media.

12:39PM Q53.00008 Fabrication of sophisticated two-dimensional organic nanoarchitectures thought hydrogen bond mediated molecular self assembly¹,

FABIEN SILLY, CEA Saclay — Complex supramolecular two-dimensional (2D) networks are attracting considerable interest as highly ordered functional materials for applications in nanotechnology. The challenge consists in tailoring the ordering of one or more molecular species into specific architectures over an extended length scale with molecular precision. Highly organized supramolecular arrays can be obtained through self-assembly of complementary molecules which can interlock via intermolecular interactions. Molecules forming hydrogen bonds (H-bonds) are especially interesting building blocks for creating sophisticated organic architectures due to high selectivity and directionality of these bindings. We used scanning tunnelling microscopy to investigate at the atomic scale the formation of H-bonded 2D organic nanoarchitectures on surfaces. We mixed perylene derivatives having rectangular shape with melamine and DNA base having triangular and non symmetric shape respectively. We observe that molecule substituents play a key role in formation of the multicomponent H-bonded architectures. We show that the 2D self-assembly of these molecules can be tailored by adjusting the temperature and molecular ratio. We used these stimuli to successfully create numerous close-packed and porous 2D multicomponent structures.

¹The research leading to these results has received funding from the European Research Council under the European Union's Seventh Framework Programme (FP7/2007-2013) / ERC grant agreement no 259297.

12:51PM Q53.00009 Exploiting Mixed Self-Assembled Monolayers for Design and Fabrication of Patchy Particles¹,

INES PONS-SIEPERMANN, SHARON GLOTZER, Department of Chemical Engineering, University of Michigan — Previous computational studies [1,2] explained the formation of patterns (stripes and patches) in binary mixtures of immiscible surfactants adsorbed on gold nanoparticles [3]. These patterns can confer to the particles unexpected properties, including novel wetting behavior [4]. As an extension of those studies, we performed atomistic and mesoscale simulations of ternary and quaternary mixed self-assembled monolayers (SAMs) on nanosphere surfaces. Here we present predictions for new and unexpected patterns for patchy particles that could be synthesized through judicious choice of surfactant architecture, nanoparticle geometry, and SAM stoichiometry.

1:03PM Q53.00010 Entropy density and Mutual Information measures to quantify the complexity of a nanoscale system ,

ILYA GRIGORENKO, VINCENT CRESPI, Penn State — Information-theoretic approach is the most general way to quantify complexity of nanoscale systems. In this study the entropy density and mutual information measures were used to identify the optimal interaction parameters between nanoparticles, which lead to the maximum geometric complexity of self-assembled nanostructures. A generalization of complexity measures at a finite temperature and for nonequilibrium systems is also presented. The developed theory can be used for efficient in silico design of new self-assembled nanostructures with a complex geometry not achievable before.

1:15PM Q53.00011 Road Usage Heterogeneity and Mitigation of Traffic Congestion ,

MARTA C. GOMZALEZ, PU WANG, MIT — Road networks form the backbone of the social and economic life of a city. Until recently, however, data have not been available to study the impact of trip selection on traffic congestion at an urban scale. To that end, we combined the most complete record of daily trips with the detailed road GIS data to analyze the road usage patterns in two US metropolitan areas. We classify the importance of road segments based on their ability to attract drivers from diverse sources and find that most of them are mainly used by drivers from very few sources. Thanks to this heterogeneity, we find that it is possible to design an efficient strategy to largely reduce the travel time in the road system.

1:27PM Q53.00012 Rippling “instability” in granular jet impact is a memory effect ,

NICHOLAS GUTTENBERG, WENDY ZHANG, JAKE ELLOWITZ, University of Chicago — Experiments and simulations of a dense granular jet impacting a target give rise to a collimated outflow despite the lack of cohesion in the system. This outflow eventually breaks up far away from the target. The breakup, however, is not a uniform dilution but rather takes the form of a series of wave-like undulations with a wavelength much larger than the grain scale. We investigate the possibility that this is another continuum hydrodynamic analog reproduced by bulk granular motion using 2D simulations. We find that these waves, unlike a Helmholtz instability, cannot readily be nucleated by perturbations of the granular flow surface. Instead, we find that they point to relics of the velocity fluctuations caused by the impact itself. We show that the ripples are an effect of the effectively ballistic flow far from the target remembering these original velocity fluctuations.

1:39PM Q53.00013 Transient Memories in Non-Equilibrium Disordered Systems ,

JOSEPH PAULSEN, SIDNEY NAGEL, University of Chicago — Some non-equilibrium systems can store information of their external driving in an unexpected manner. They “learn” multiple driving amplitudes that can subsequently be read out. Notably, only one memory is retained after many driving cycles, even if all of the amplitudes are continually fed in. This behavior has been observed in diverse scenarios such as traveling charge-density waves [1] and simulations of sheared suspensions [2]. Here we explore this latter system experimentally using a suspension of neutrally buoyant non-Brownian particles in a very viscous fluid that is sheared cyclically in a Couette cell geometry. Starting from a random configuration, the particle trajectories are irreversible at first but, as had been shown [3], eventually settle into a configuration where they retrace their paths exactly during each cycle. We show that the resulting configuration comprises a memory of the driving amplitude, which can be read out by measuring the degree of particle reversibility versus shear amplitude. We also discuss this system's capacity for storing multiple memories.

1:51PM Q53.00014 Role of interaction in the formation of memories in paste , AKIO NAKAHARA, YOUSUKE MATSUO, Nihon University — A densely packed colloidal suspension with plasticity, called paste, remembers the directions of vibration and flow. These memories in paste can be visualized by the morphology of desiccation crack patterns. We investigate the role of interaction in the formation of memories in paste. First, interparticle attractive forces, such as van der Waals interaction, are needed to construct a macroscopic network structure with plasticity. With the help of attractive interaction, a water-poor paste remembers the direction of vibration and a water-rich paste remembers the flow direction [1]. When particles are charged in water, however, Coulombic repulsive interaction prevents formation of dilute network structure under flow, which leads to the experimental result that a water-rich charged paste cannot remember flow direction. Addition of sodium chloride to such a paste gives the ability to remember flow direction due to the screening effect of Coulombic repulsive interaction between particles [2].

2:03PM Q53.00015 Resonances arising from hydrodynamic memory - The Color of Brownian motion , SYLVIA JENEY, MATTHIAS GRIMM, FLAVIO MOR, LASZLO FORRO, Ecole Polytech Fed de Lausanne, THOMAS FRANOSCH, Universitaet Erlangen-Nuernberg — Observation of the Brownian motion of a small probe interacting with its environment is one of the main strategies to characterize soft matter. Initially, the particle is driven by rapid collisions with the surrounding solvent molecules, referred to as thermal noise. Later, the friction between the particle and the viscous solvent damps its motion. Conventionally, thermal force is taken to be characterized by a Gaussian white noise spectrum. The friction is assumed to be given by the Stokes drag, suggesting that motion is overdamped at long times, when inertia becomes negligible. Here, we measured the noise spectrum of the thermal forces by tracking with high resolution a single micron-sized sphere suspended in a fluid, and confined by a stiff optical trap [1]. Coupling between sphere and fluid gives rise to hydrodynamic memory [2] and a resonance, equivalent to a colored peak in the power spectral density of the sphere's thermal fluctuations. Our results reveal that motion is not overdamped, even at long times. In view to exploit the particle-fluid-trap system as a nanomechanical resonator, we disentangle the two regimes in which the detected resonance is either sensitive to the fluid properties or to the particle's mass.

Wednesday, February 29, 2012 11:15AM - 2:15PM – Session Q54 DCMF: Superconductivity: Mesoscopic and Nanometer Scale 152

11:15AM Q54.00001 Designing high-impedance/low-noise superinductances for quantum electronics¹ , IOAN POP, ZLATKO MINEV, NICHOLAS MASLUK, ARCHANA KAMAL, MICHEL DEVORET, Yale University, Applied Physics — Superinductances are essential circuit elements which enable the suppression of charge fluctuations in superconducting fluxonium qubits [1] and in other Josephson junction devices [2]. Commonly implemented as an array of Josephson junctions, superinductances have two main limitations. Firstly, the spurious capacitive coupling of the chain islands to ground lowers the plasma frequency of the chain, and consequently limits the operational bandwidth. Secondly, coherent quantum phase-slips (CQPS) [3] in the Josephson junction chain induce time dependent inductance fluctuations via the Aharonov-Casher effect [4]. We present the application of a novel lithographic technique [5] which enables the fabrication of arrays with optimal junction-capacitance to ground-capacitance ratio. We also present new superinductance designs which topologically suppress the CQPS, allowing the implementation of practically phase-slip free high inductance Josephson junction.

11:27AM Q54.00002 Powerful coherent terahertz emission from $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ mesa array¹ , TIMOTHY BENSEMAN, KEN GRAY, ALEXEI KOSHELEV, WAI-KWONG KWOK, ULRICH WELP, Materials Science Division, Argonne National Laboratory, HIDETOSHI MINAMI, KAZUO KADOWAKI, Institute for Materials Science, University of Tsukuba, Japan, TAKASHI YAMAMOTO, Quantum Beam Science Directorate, Japan Atomic Energy Agency — Stacks of intrinsic Josephson junctions (IJJs) in high-temperature superconductors enable the fabrication of compact sources of coherent THz-radiation. Here we demonstrate 150 microwatts of radiation power at 0.51 THz, using three synchronized stacks patterned on a single $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}$ crystal. The emitted power scales roughly as the square of the number of energized stacks, while the total power spectrum is monochromatic to within observational limits. These results imply that the stacks radiate coherently.

11:39AM Q54.00003 DC SQUID RF magnetometer with 200 MHz bandwidth¹ , VLADIMIR TALANOV, NESCO LETTSOME, ANTONIO OROZCO, Neocera, LLC, Beltsville, MD 20705, ALFRED CAWTHORNE, Trevecca Nazarene University, Nashville, TN 37210, VALERY BORZENETS, SLAC National Accelerator Laboratory, Menlo Park, CA 94025 — Because of periodic flux-to-voltage transfer function, Superconducting QUantum Interference Device (SQUID) magnetometers operate in a closed-loop regime [1], which linearizes the response, and increases the dynamic range and sensitivity. However, a transmission line delay between the SQUID and electronics fundamentally limits the closed-loop bandwidth at 20 MHz [1], although the intrinsic bandwidth of SQUIDS is in gigahertz range. We designed a DC SQUID based RF magnetometer capable of wideband sensing coherent magnetic fields up to 200 MHz. To overcome the closed-loop bandwidth limitation, we utilized a low-frequency flux-modulated closed-loop to simultaneously lock the quasi-static magnetic flux and provide AC bias for the RF flux. The SQUID RF voltage is processed by RF electronics based on a double lock-in technique. This yields a signal proportional to the amplitude and phase of the RF magnetic flux, with more than four decades of a linear response. For YBaCuO SQUID on bi-crystal SrTiO substrate at 77 K we achieved a flux noise density of $4 \mu\Phi_0/\sqrt{\text{Hz}}$ at 190 MHz, which is similar to that measured at kHz frequencies with conventional flux-locked loop. [1] D. Drung, *et al.*, Supercond. Sci. Technol. **19**, S235 (2006).

11:51AM Q54.00004 Wideband S-parameter characterization of DC-SQUID amplifiers at GHz frequencies, LEONARDO RANZANI, LAFE SPIETZ, JOSE AUMENTADO, NIST, Boulder — Superconducting quantum interference devices (SQUIDs) are widely used as gain elements to achieve ultra-low noise amplification from DC to microwave frequencies. SQUID amplifiers typically have high input and output stray reactance and therefore proper impedance matching is needed to couple enough power into the device. Broadband impedance matching could be obtained by measuring the microwave S-parameters of a SQUID amplifier and then treating it as an equivalent “black box” to which standard microwave design techniques can be applied. In this talk measurement results of the full 2-port S-parameter matrix of DC-SQUID amplifiers operating at 20mK will be presented. Accurate microwave calibration was performed with an automated Through-Reflect-Line (TRL) calibration system, operating at 20mK. Input and output reflection coefficients as well as forward and backward transmission were characterized in the 1 to 8GHz range. Implications for the design of wideband SQUID amplifiers and device stability will be discussed.

12:03PM Q54.00005 Characterization of Low Noise Superconducting Microwave Amplifiers, TED WHITE, University of California Santa Barbara, R. BAREND, J. BOCHMANN, B. CHIARO, Y. CHEN, J. KELLY, M. LENANDER, E. LUCERO, M. MARIANTONI, A. MEGRANT, C. NEILL, P. O'MALLEY, P. ROUSHAN, D. SANK, A. VAINSENER, J. WENNER, Y. YIN, ANDREW CLELAND, JOHN M. MARTINIS, UC Santa Barbara — We have developed an experimental setup to characterize low noise amplifier chains with a six port low temperature microwave switch controlled via room temperature electronics. This switch allows us to do a traditional Y-factor measurement, a reflection measurement with an open input, or a measurement using a Shot Noise Tunnel Junction (SNTJ) device developed by J. Aumentado and L. Spietz at NIST. The SNTJ allows one to measure system gain, system noise, and junction temperature as fit parameters. The SNTJ is sensitive enough to characterize amplifiers with noise due primarily to photon ground state fluctuations or quantum limited amplifiers. We first tested our setup using a HEMT and room temperature amplifier chain with calibrated noise and gain characteristics. We then characterized several iterations of the theoretically quantum limited SLUG amplifier developed by R. McDermott at U Wisconsin Madison.

12:15PM Q54.00006 Shot noise measurements in diffusive wire NSN structures¹, MARTIN STEHNO, D.J. VAN HARLINGEN, University of Illinois at Urbana-Champaign — Subgap transport across a normal metal/superconductor interface requires a conversion from normal to supercurrent. We study the conversion process in superconducting wire samples by attaching two short diffusive normal metal wires at a distance comparable to the coherence length in the superconductor. In addition to ordinary Andreev reflection, nonlocal processes involving electronic states in both contacts (Crossed Andreev reflection, and Elastic Co-tunneling) are expected to contribute and to give rise to a cross-conductance signal in transport measurements. As one of the wire contacts is biased into the shot noise regime, a significant increase of current fluctuations is observed in the other (unbiased) contact. Only a small fraction of the noise measured in the two contacts is correlated. The magnitude of the correlated signal scales with the observed cross-conductance. We will compare our results with theoretical predictions for nonlocal transport and previous experimental work.

12:27PM Q54.00007 Toward a Passive Lossless on-Chip Circulator in the 4-8 GHz Range, LAFE SPIETZ, JOSE AUMENTADO, NIST — We present further progress toward constructing a passive microwave circulator from Josephson junction circuits. We have designed, built and tested a circuit which demonstrates the basic properties required to construct a gyrator in the 4-8 GHz range. We describe the theory and present the data on this circuit and point to the path from these results to practical passive lossless on-chip circulators.

12:39PM Q54.00008 Calibration of a Microfabricated Phonon Spectrometer, JARED HERTZBERG, OBAFEMI OTELAJA, RICHARD ROBINSON, Cornell University, Department of Materials Science and Engineering — Non-thermal distributions of phonons may be locally excited and detected in silicon micro- and nanostructures by decay of quasiparticles injected into an adjacent superconducting tunnel junction [1]. Using this technique, narrow frequency bands of phonons may be isolated and applied to investigate phonon transport through nanostructures at sub-kelvin temperatures [2]. In our prototype phonon spectrometer we have demonstrated spatial resolution below 1 micron and frequency resolution of 10 GHz. We describe ways to control the spatial resolution, frequency resolution, frequency range, dynamic range and signal-to-noise ratio in this technique, by using different superconducting materials in the tunnel junctions and by inserting absorber materials into the phonon transmission path. This work is supported by DOE (DE-SC0001086).

12:51PM Q54.00009 Microwave Spectroscopy of a Cooper-Pair Transistor Coupled to a Lumped-Element Resonator, MATTHEW BELL, LEV IOFFE, MICHAEL GERSHENSON, Department of Physics and Astronomy, Rutgers, the State University of New Jersey — We have studied the microwave response of a single Cooper-pair transistor (CPT) coupled to a lumped-element microwave resonator. The resonance frequency of this circuit, f_r , was measured as a function of the charge n_g induced on the CPT island by the gate electrode, and the phase difference across the CPT, ϕ_B , which was controlled by the magnetic flux in the superconducting loop containing the CPT. The observed $f_r(n_g, \phi_B)$ dependences reflect the variations of the CPT Josephson inductance with n_g and ϕ_B as well as the CPT excitation when the microwaves induce transitions between different quantum states of the CPT. The results are in excellent agreement with our simulations based on the numerical diagonalization of the circuit Hamiltonian. This agreement over the whole range of n_g and ϕ_B is unexpected, because the relevant energies vary widely, from 0.1K to 3K. The observed strong dependence $f_r(n_g, \phi_B)$ near the resonance excitation of the CPT provides a tool for sensitive charge measurements.

1:03PM Q54.00010 Superconducting Low-Inductance Undulatory Galvanometer Microwave Amplifier: Theory, DAVID HOVER, GUILHEM RIBEILL, YUNG-FU CHEN, SHAOJIANG ZHU, ROBERT MCDERMOTT, University of Wisconsin-Madison — We present numerical studies of a phase-insensitive microwave linear amplifier based on the Superconducting Low-Inductance Undulatory Galvanometer (SLUG). Direct integration of the junction equations of motion provides access to the full scattering matrix of the SLUG element. We discuss the optimization of SLUG amplifiers and calculate amplifier gain and noise temperature in both the thermal and quantum regimes. The microwave SLUG amplifier is expected to achieve noise performance approaching the standard quantum limit in the frequency range from 5-10 GHz, with gain around 15 dB for a single-stage device and instantaneous bandwidth of order hundreds of MHz. We compare our numerical model with measured performance of state-of-the-art devices.

1:15PM Q54.00011 Superconducting Low-inductance Undulatory Galvanometer Microwave Amplifier, SHAOJIANG ZHU, DAVID HOVER, GUILHEM RIBEILL, YUNG-FU CHEN, ROBERT MCDERMOTT, University of Wisconsin — We describe a novel microwave linear amplifier based on the Superconducting Low-inductance Undulatory Galvanometer (SLUG). The compact SLUG element is straightforward to model at microwave frequencies, allowing separate optimization of the SLUG element and the resonant input matching network; we expect optimized devices based on high-Jc junctions to achieve gains around 15 dB in the range from 5-10 GHz, with instantaneous bandwidth of order hundreds of MHz and noise performance approaching the standard quantum limit. Using amplifiers based on low-Jc Al/AIO_x/Al junctions, we have achieved gain in excess of 20 dB at 3 GHz and greater than 15 dB at 9 GHz with bandwidth of several MHz. We discuss progress toward the incorporation of high-Jc Nb/AIO_x/Nb junctions in the SLUG amplifier, and describe strategies to promote the thermalization of the SLUG shunt resistors at dilution refrigerator temperatures by integrating large-volume normal metal cooling fins with the shunts.

1:27PM Q54.00012 Development and Implementation of a 1 GHz SQUID amplifier for the Axion Dark Matter Experiment, ANDREW WAGNER, University of Washington, AXION DARK MATTER EXPERIMENT COLLABORATION — The Axion Dark Matter eXperiment (ADMX) was designed to detect ultra-weakly interacting relic axion particles by searching for their conversion to microwave photons in a resonant cavity positioned in a strong magnetic field. Given the extremely low expected axion-photon conversion power we have designed, built and operated a microwave receiver based on a Superconducting QUantum Interference Device (SQUID). We describe the implementation of a SQUID amplifier in the ADMX microwave receiver chain and discuss progress made at the Washington Micro-Fabrication Facility toward the production of SQUID amplifiers from a Nb – Al_xO_y – Nb trilayer.

1:39PM Q54.00013 Quantum pumping of electrons at the Josephson frequency, FRANCESCO GIAZOTTO, PANAYOTIS SPATHIS, STEFANO RODDARO, SUBHAJIT BISWAS, FABIO TADDEI, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Piazza S. Silvestro 12, I-56127 Pisa, Italy, MICHELE GOVERNALE, School of Chemical and Physical Sciences and MacDiarmid Institute for Advanced Materials and Nanotechnology, Victoria University of Wellington, P.O. B, LUCIA SORBA, NEST, Istituto Nanoscienze-CNR and Scuola Normale Superiore, Piazza S. Silvestro 12, I-56127 Pisa, Italy — A macroscopic fluid pump works according to the law of Newtonian mechanics and transfers a large number of molecules per cycle. By contrast, a nano-scale charge pump can be thought as the ultimate miniaturization of a pump, with its operation being subject to quantum mechanics and with only few electrons or even fractions of electrons transferred per cycle. It generates a direct current in the absence of an applied voltage exploiting the time-dependence of some properties of a nano-scale conductor. So far, nano-scale pumps have been realised only in system exhibiting strong Coulombic effects, whereas evidence for pumping in the absence of Coulomb-blockade has been elusive. Here we report the experimental detection of charge flow in an unbiased InAs nanowire embedded in a superconducting quantum interference device (SQUID). In this system, pumping occurs via the cyclic modulation of the phase of the order parameter of different superconductors. The symmetry of the current with respect to the enclosed flux and SQUID current is a discriminating signature of pumping. Currents exceeding 20 pA are measured at 250 mK, and exhibit symmetries compatible with a pumping mechanism.

1:51PM Q54.00014 NIS cooler platform: from 300 mK to 100 mK, THOMAS AREF, JUHA MUHONEN, HUNG NGUYEN, JOONAS PELTONEN, MATTHIAS MESCHKE, JUKKA PEKOLA, Low Temperature Laboratory, Aalto University, Finland — Normal-insulator-superconducting (NIS) tunnel junctions allow cooling of the normal metal by electrons tunneling across the insulating barrier. With proper biasing, hot electrons leave the normal metal and cold electrons enter from the superconductor, lowering the electronic temperature. The heat dissipation is determined primarily by the quasiparticle relaxation in the superconducting leads. We explore the effects of magnetic field, electrode geometry, direct quasiparticle traps and other fabrication modifications on cooler effectiveness. The overall aim is to produce a general electronic cooler for efficient, solid state, cooling of small devices from 300 to 100 mK.

2:03PM Q54.00015 Implementation and test of an Levitov's n-electron coherent source¹, JULIE DUBOIS, THIBAUT JULLIEN, PREDEN ROULLEAU, FABIEN PORTIER, PATRICE ROCHE, D. CHRISTIAN GLATTLI², Service de Physique de l'Etat Condensé, CEA Saclay — Injecting a controlled number of electrons in a quantum ballistic conductor opens the way to new kind of quantum experiments, yet never done. It is well known that a voltage biased contact applied on a single mode quantum conductor, such as a Quantum Point Contact, inject continuously single electrons at a rate eV/h , a remarkable property of the Fermi sea. Here we consider the injection of electrons during a very short time where is expected that a voltage pulse with $\int eV(t)dt = nh$ injects exactly n-electrons, n being integer. If in addition, if the voltage pulse has the form of a Lorentzian shape in time, Levitov has shown that the n-electron are not accompanied by neutral spurious electron-hole pair excitations and thus form a minimal excitation n-electron source. The electron being indistinguishable if the time-scale is shorter than the coherence time, the Levitov's source is coherent and new quantum experiments involving interference with several electrons become at reach. We present here experimental realization of the n-electron source using short sub-nanosecond pulses and tests of the minimal excitation number using the shot noise created by repeatedly sending n-electrons toward a quantum point realized in clean ballistic 2D electrons. The square-wave, sine-wave and Lorentzian shape pulses are compared. This is also accompanied by photon-assisted current measurements. J. Dubois, T. Jullien, P. Roulleau, F. Portier, P. Roche, and D.C. Glatthi, in preparation.

S1.00001 APPLICATIONS (IT, Medical/Bio, Photonics, etc.) —

S1.00002 Charge Transport Anisotropy in n-Type Disk-Shaped Triphenylene-Tris(aryleneimidazole)s, STEVEN ALVAREZ, YUE ZHANG, DAVID HANIFI, FRANCISCO ANTONIO, ANDREW PUN, LIANA KLIVANSKY, ALEXANDER HEXEMER, BIWU MA, YI LIU, Lawrence Berkeley National Laboratory — Two novel n-type disk-shaped molecules containing a triphenylene core and three fused naphthaleneimide imidazole or peryleneimide imidazole “arms” are synthesized and characterized. Their optical and electronic properties are consistent with the pi-extended structural feature of the aromatic cores. The n-type charge carrier mobilities of these molecules are evaluated by both field effect transistors and space-charge limited-current measurements, which show drastically different mobility anisotropy. A strong correlation between film morphology and the charge transport behavior is established by X-ray scattering and atomic force microscopic analyses.

S1.00003 Identification of the Amorphous $\text{AlB}_4\text{H}_{11}$ Structure¹, YONGLI WANG, YONGSHENG ZHANG, Northwestern University, XUENIAN CHEN, JI-CHENG ZHAO, The Ohio State University, WEI ZHOU, TERRENCE UDOVIC, National Institute of Standards and Technology, C. WOLVERTON, Northwestern University — In recent experimental work, $\text{AlB}_4\text{H}_{11}$ has been identified as a potential hydrogen storage material with a good desorption temperature and partial reversibility. It is an amorphous, white solid at room temperature and its molecular structure is presently unknown. We combine experimental measurements (NMR, neutron vibrational spectra and IR) and a theoretical structure prediction method to identify the (local) structure of the amorphous $\text{AlB}_4\text{H}_{11}$ phase. The theoretical structure prediction method is a combination of the Monte-Carlo based prototype electrostatic ground state search (PEGS) method and first-principles calculation (DFT). The PEGS+DFT method has successfully predicted many crystalline solid structures, but has never been applied to the prediction of amorphous solid structures. The PEGS predictions of the $\text{AlB}_4\text{H}_{11}$ structure are quite successful: we find the calculated phonon density of states (pDOS) of our PEGS+DFT predicted structures is in close agreement with the experimental vibrational measurements. More broadly, our findings indicate that first-principles theoretical design of new amorphous materials for energy storage is now possible, paving a promising way for similar studies in the future.

S1.00004 Influence of xc functional on thermal-elastic properties of metal oxides: A DFT-based Debye-Grüneisen model approach, TAEHUN LEE, ALOYSIUS SOON, Yonsei University, Seoul, Korea — For high-temperature applications, the chemical stability, as well as the mechanical integrity of the oxide material used is of utmost importance. Solving these problems demands a thorough and fundamental understanding of their thermal-elastic properties. In this work, we report density-functional theory (DFT) calculations to investigate the influence of the xc functional on specific thermal-elastic properties of some common oxides CeO_2 , Cu_2O , and MgO . Namely, we consider the local-density approximation (LDA), the generalized gradient approximation due to Perdew, Burke, and Ernzerhof (GGA-PBE), as well as a recently popularized hybrid functional due to Heyd-Scuseria-Ernzerhof (HSE06). In addition, we will also report DFT+ U results where we introduce a Hubbard U term to the Cu $3d$ and the Ce $4f$ states. Upon obtaining the DFT total energies, we then couple this to a volume-dependent Debye-Grüneisen model [1] to determine the thermodynamic quantities of these oxides at arbitrary pressures and temperatures. We find an explicit description of the strong correlation (e.g. via the DFT+ U approach and using HSE06) is necessary to have a good agreement with experimental values. [1] A. Otero-de-la-Roza, D. Abbasi-Pérez et al. *Com. Phys. Com.* 182 (2011) 2232

S1.00005 Towards solar cells combining silicon nanopillars and various semiconductor nanoparticles¹, D. STIEVENARD, CNRS, Y. LAMBERT, ISEN, DI ZHOU, Univ de Lille, T. XU, ISEN, B. GRANDIDIER, N. RAMESH PRATIBHA, F. GOURBILLEAU, CNRS, S. TURRELL, C. KINOWSKI, O. ROBBE, Univ de Lille, G. PAN, R. BOUKHERROUB, CNRS, W. CHEN, R. LARDE, P. PAREIGE, Univ de Rouen, J. HABINSHUTTI, Univ de Lille, IEMN TEAM, CIMAP TEAM, LASIR TEAM, IRI TEAM, GPM TEAM — We have developed solar cells combining silicon nanopillars and various semiconductor nanoparticles-NPs- (silicon or CdSe ones obtained by chemical synthesis or silicon ones obtained by thermal annealing of multilayer structure $\text{Si-SiO}_2(2)/\text{SiN}(x)$ fabricated by reactive magnetron sputtering.). Nanopillars are obtained by standard RIE process using silica spheres as active mask for the etching. NPs are chemically grafted or deposited by Langmuir Blodgett technique on the p-type pillars and therefore covered by a thin polysilicon n type layer. The doping level and of the different interfaces are monitored by 3D Atom Probe Tomography. Photocurrents curve without and with NPs will be presented, evidencing the NPs active role.

¹Work partly supported by DGA contract REI 2008 34 0031.

S1.00006 An Antireflective Top Contact for Optoelectronic Devices Using Niobium Doped Titanium Dioxide, JOHN CHIVERS, THOMAS VANDERVELDE, Tufts University, REAP LABS TEAM — We present an investigation of an integrated top contact system for optoelectronic semiconductor devices (e.g. solar cells, photo-detectors, etc.). Niobium-doped titanium dioxide (TNO) is used as a transparent conductor and a graded $\text{TiO}_2/\text{SiO}_2$ layer with a nanostructured SiO_2 surface is added to suppress reflection and improve durability. TNO was chosen to replace indium tin oxide (ITO), the industry standard transparent conductor, in an effort to reduce dependence on increasingly scarce resources (i.e. indium). TNO offers other potential benefits over ITO, including superior durability, higher index of refraction, and superior transparency in the infrared. The graded antireflective layer takes advantage of the common crystalline structure of TiO_2 and SiO_2 , making fabrication simpler and more reliable than would be possible if the materials had differing structures. The nanostructured SiO_2 surface uses a “moth’s eye” pattern of sub-wavelength-scale cones to create a gradual optical transition from ambient air to the SiO_2 . All materials are deposited using RF magnetron sputtering. Results are compared to current standards and the strengths and weaknesses of the TNO system are discussed.

S1.00007 Thermal Properties of Polarization Switching in Vertical-Cavity Surface-Emitting Lasers, YU-HENG WU, YUEH-CHEN LI, WANG-CHUANG KUO, TSU-CHIANG YEN, Department of Physics, National Sun Yat sen University — This investigation studied the thermal properties of the polarization switching (PS) in vertical-cavity surface-emitting lasers (VCSELs). The studies were performed by experiments. In experiments, the current modulation frequency and ambient temperature of VCSELs were varied to study their thermal effects on PS. The hysteresis loop of polarization switching broadens as the modulation frequency increased and narrows as the modulation frequency decreased. We assumed that PS is activated as the temperature in the active region reaches a certain temperature. The PS of the VCSEL controlled by continuously varied ambient temperature is also studied. The experiments results show that the thermal effect plays a major role in PS and the hysteresis of PS. These results contribute to the understanding of the mechanism of VCSEL’s polarization switching.

S1.00008 Temperature dependence of the null hysteresis loop in polarization switching of vertical-cavity surface-emitting lasers, YUEH-CHEN LI, YU-HENG WU, WANG-CHUANG KUO, TSU-CHIANG YEN, Department of Physics, National Sun Yat sen University — This research investigated the frequency-dependent polarization switching hysteresis loop (PSHL) of vertical-cavity surface-emitting lasers (VCSELs) in constant ambient temperature. The special feature of VCSELs is the polarization switching (PS). In most case, the switching current in the rise and decline bias are not the same, and shows hysteresis. The ambient temperature was controlled in this experiment. The hysteresis loop width of polarization switching disappears as the modulation frequency is lower than a critical frequency. Experimental results show that the critical frequency depends on the ambient temperature. Experimental data presents that the thermal effect plays a major role in the hysteresis of PS. These results greatly contribute to the understanding of the VCSEL’s PSHL.

S1.00009 Linear and nonlinear properties in soft glass optical fibers for device applications, LEILY KIANI, Physics and Chemistry, School of Natural Sciences, University of California, Merced, TILANKA MUNASINGHE, WEN QI ZHANG, SHAHRAAM AFSHAR, Institute for Photonics and Advanced Sensing (IPAS), School of Chemistry and Physics, University of Adelaide, Australia, JAY SHARPING, Physics and Chemistry, School of Natural Sciences, University of California, Merced, APPLIED PHOTONICS GROUP AND INSTITUTE FOR PHOTONICS AND ADVANCED SENSING (IPAS) COLLABORATION — Optical fiber technology is predominantly based on silica glass fibers. Non-silica soft glass fibers exhibit substantially different optical properties such as higher refractive index, larger nonlinear coefficient and structural fabrication flexibility. We aim to exploit these novel properties for device applications such as sensing and light generation. We report measurement of linear dispersion and nonlinear coefficient in the range of $1.5\ \mu\text{m}$ in two custom designed soft glass microstructure optical fibers. The fibers are composed of SF57 (Schott) and Bismuth-doped silica (Asahi Glass Co.) respectively with Hexagonal Wagonwheel microstructure design. These fibers are designed to allow phase matching of nonlinear optical processes near $1.6\ \mu\text{m}$. Our measurements indicate nonlinear coefficients 1000 times that of standard silica fiber. Transverse modes in these fibers are difficult to separate leading to a complicated dispersion results. Next steps include observation of parametric generation and Brillouin gain.

S1.00010 Observation of New Photoluminescence Emission in the YAG Structure and Its significant Effects on the Material Optical Properties¹, FARIDA SELIM, CHRISTOPHER VARNEY, SHERIF REDA, DAVID MACKAY, Washington State University — Yttrium Aluminum Garnets, $\text{Y}_3\text{Al}_5\text{O}_{12}$ (YAG) are widely used as host materials for transition and rare earth elements in laser, optoelectronic and scintillation applications. They are the most important solid state laser host materials and the most promising scintillation materials. New photoluminescence peaks were observed at 700 and 800 nm in undoped yttrium aluminum garnet (YAG) single crystals. This luminescence has great effects on the optical properties of rare-earth doped YAG crystals and their performance in laser and scintillation applications. Photoluminescence measurements revealed a number of luminescence peaks in all YAG crystals regardless of the growth conditions due to native defects and low-level impurities. The strong 700 and 800 nm emissions were attributed to low level of iron impurities as confirmed by Glow Discharge Mass Spectrometry analysis. This study reveals that iron is a native impurity in all YAG crystals that plays a significant role on modifying the optical and scintillation properties of this important class of photonic materials.

¹This work was funded by NSF (DMR 1006772)

S1.00011 Development of new semi-rigid coaxial cables for low temperature experiments, AKIHIRO KUSHINO, Asahikawa National College of Technology, SOICHI KASAI, COAX CO., LTD. — Coaxial cables with seamless outer electrical conductors are promising for low-noise readout from novel cryogenic devices such as superconducting radiation or particle detectors, operating below helium temperature. Low thermal conductance as well as small signal attenuation is essential in wiring with coaxial cables for array detectors consisting of hundreds of pixels. We developed thin semi-rigid coaxial cables employing normal alloys (CuNi, SUS and beryllium copper) and superconducting alloys (NbTi and Nb). Superconducting coaxial cables with outer diameters from 0.86 mm to 2.19 mm showed good superconducting transitions at 9–10 K, and flat attenuation properties up to above 5 GHz.

S1.00012 Investigation of 1/f flux noise in superconducting circuits, A. PUGLIELLI, S. SENDELBACH, Department of Physics, University of Wisconsin-Madison, C.B. EOM, J. PODKAMINER, K.H. CHO, Department of Materials Science and Engineering, University of Wisconsin-Madison, R. MCDERMOTT, Department of Physics, University of Wisconsin-Madison — Low-frequency 1/f flux noise is a dominant source of dephasing in the Josephson phase and flux qubits. Recent work has revealed the presence of a high density of unpaired spins at the surfaces of superconducting thin films; it is now believed that these spins are the source of the noise, although the microscopic noise mechanism is not understood. Here we describe experiments on SQUIDS and Josephson phase qubits designed to shed light on the underlying noise mechanism, and we describe efforts to develop novel materials with reduced levels of noise.

S1.00013 Biompatible gold nanorods conjugated with photosensitizers assisted for photostability and photodestructive ability, WEN-SHUO KUO¹, SHEAN-JEN CHEN², National Cheng Kung University — Light-exposure-mediated higher temperatures that markedly accelerate the degradation of indocyanine green (ICG) in aqueous solutions by thermal decomposition have been a serious medical problem. In this work, we present the example of using gold nanorods (Au NRs) simultaneously serving as photodynamic and photothermal agents to destroy malignant cells. Au NRs were successfully conjugated with hydrophilic photosensitizer, indocyanine green (ICG), to achieve photodynamic therapy (PDT) and photothermal therapy (PTT). We also demonstrated that Au NRs conjugated with ICG displayed high chemical stability and acted as a promising diagnostic probe. Due to its stability even via higher temperatures mediated by laser irradiation, the combination of PDT and PTT proved to be efficiently killing cancer cells as compared to PDT or PTT treatment alone and enhanced the effectiveness of photodestruction and was demonstrated to enhance its photostability.

²Advanced Optoelectronic Technology Center, Department of Engineering Science

S1.00014 Encapsulation of Protoporphyrin IX in PGLA for Biological Applications, BRIAN BUI, UT Arlington, NANOBIO-PHYSICS GROUP TEAM — In biological studies, Protoporphyrin IX has been utilized in researching with photodynamic therapy. With different situations that arise, it is beneficial to have products tailored to the given investigation. Here we propose encapsulating Protoporphyrin IX into poly(lactic-co-glycolic acid) (PLGA) with different parameters in hopes of obtaining products with necessary properties, including photoluminescent intensity, size and loading levels. We hypothesize the intensity of Protoporphyrin IX can be tuned, and this study will help to find the conditions for intensity change. We use chloroform and PVA solutions in the emulsion extraction/evaporation. The extraction and evaporation phases are different such that we can get particles sooner or later, respectively, which can lead to differences in loading levels. We vary diverse parameters, including volumes of the organic solvent, the aqueous solution, the drug volume (consisting of Protoporphyrin IX in a solvent). The products PLGA-Protoporphyrin IX (Pppix) were obtained, characterized and optical properties were observed.

S1.00015 Hydrothermal Solution-Processed Reduced Nano-Graphene Oxide as Blue Photoluminescence Quantum Dots, JIGANG WANG, University of Texas Arlington, YONGSHENG WANG, DAWEI HE, Beijing Jiao Tong University, KE JIANG, WEI CHEN, University of Texas Arlington — Chemical derived graphene oxide, an atomically thin sheet of graphite with 2-D construction, offers interesting electronic, chemical and mechanical properties that are currently being explored for advanced electronics, membranes and composites. Herein, we synthesize and explore the blue photoluminescence (PL) nano-graphene quantum dots (QD) through hydrothermal-solution-processed reduced graphene oxide. The PL investigation indicated that graphene oxide solution showed weak fluorescence. However, when the nano-graphene oxide solution samples were heated at different temperatures, from 200–300 °C, the blue PL intensity of the solution improved radically as heating temperature increased. We also investigated time dependence at a certain heating temperature and the PL Intensity and peak based on graphene QDs under different pH values by adding NaOH. The FT-IR measurements showed that the functional groups of the graphene oxide had been altered due to the hydrothermal routes. In addition, we also investigated the absorption spectrum of the graphene QDs under different conditions, XRD and XPS images of the graphene oxide, TEM and SEM images based on graphene QDs under different conditions.

S1.00016 Nanocomposite for radiation detection, SUNIL SAHI, University of Texas at Arlington — Cerium fluoride is among the widely studied inorganic scintillators for radiation detection, because of its high light output and high stopping power. Herein, platelets shape CeF_3 nanoparticles for radiation detection was synthesis by bisolvent solvothermal method. The characterization of nanoparticles was done by photoluminescence, XRD and SEM measurement. The synthesized CeF_3 nanoparticles have broad emission peak around 330 nm. ZnO is a semiconductor scintillator, having fast decay time. ZnO nanoparticles were synthesized using solvothermal method and UV-Vis, photoluminescence and SEM measurement were done for their characterization. The absorption spectrum of the ZnO nanoparticles is dependent on the size of the nanoparticles. By changing the temperature and the concentration of zinc salt and surfactant, ZnO with absorption spectra overlapping with the emission spectra of CeF_3 were made for the purpose of creating nanocomposites, with improved scintillation properties. The energy transfer between two nanoparticles was also studied and the changes in Photoluminescence intensity of the nanocomposites were described.

S1.00017 METALS —

S1.00018 Simulating slow strain-rate processes in disordered solids , PENGHUI CAO, HAROLD S. PARK, XI LIN, Department of Mechanical Engineering, Boston University — A generic computational scheme is developed in this work to investigate extremely slow strain rate processes, including the experimentally accessible strain rates and even lower ones, for disordered materials systems. We use a self-learning metabain escape algorithm to capture the strain-rate and temperature dependent stress relaxation events for a binary Lennard-Jones alloy. It is found that the yield stress decreases when the strain rate decreases and when the temperature increases.

S1.00019 Plasmon Resonance Energy of Nickel Manganese Films , JAMIE SMITH, KEN PODOLAK, SUNY Plattsburgh — Plasmonics studies how light interacts with conductors at the nanoscale level. Plasmons result from a collective oscillation of charges. Surface plasmonics has become of interest due to the ability to confine optical energy into subwavelength volumes, however the ability to control and manipulate them has yet to be developed. In the future, plasmonics can revolutionize optical devices with increased performance speed and functionality. To alter the properties of a surface plasmon wave, an active layer is grown beneath a metal surface. Since, part of the plasmon's electromagnetic field resides in this layer, the layer couples to the surface plasmons. Thus, each sample studied was composed of an amorphous nickel manganese film grown on top of silicon with a capping copper layer. Optical absorption measurements were made with these films using a Cary-OLIS spectrophotometer from 190 – 450 nm. Two peaks in the absorption of each sample were found: one around 3.30 eV which is the surface plasmon peak as seen in previous literature and a bound electron peak at 4.45 eV. The full width half maximum of the surface plasmon peak is observed to increase when increasing the manganese concentration in each sample. A discussion as to possible reasons why will be presented.

S1.00020 Electronic States of Nickel Effected By Magnetic Doping , KEN PODOLAK, JAMIE SMITH, SUNY Plattsburgh — Spin currents have a great potential to replace charge currents. This would revolutionize how we read/write information. The generation and switching of spin currents however must be well understood. Transport measurements suggest that magnetic impurities can alter the mean free path of carriers and thereby create spin currents. Angle-resolved photoemission is used to determine the change in the electronic states of Ni induced by doping with iron, chromium, and manganese near the Fermi Energy. The samples were single crystals of nickel(110) with variable amounts of dopant diffused into it. Alloy single crystals were used over epitaxial thin films due to the sharper features at the Fermi Energy that they produced. The mean free path, magnetic splitting, and carrier density are affected by a few percent of each of the dopants. Iron suppresses the mean free path of minority spins only, while chromium and manganese suppresses both spins and decreases the magnetic splitting. The strong variation of these affects from one impurity to the other supports the concept of tailoring spin transport by magnetic doping. [1] K. N. Altmann et al., Phys. Rev. Lett. **87**, 137201 (2001) [2] K.R. Podolak, Ph.D. Thesis, Penn. State (2008)

S1.00021 COMPLEX STRUCTURED MATERIALS, INCLUDING GRAPHENE —

S1.00022 Fabrication of graphene device from graphite intercalation compound , RYUTA YAGI, HIROAKI KOBARA, MIDORI SHIMOMURA, FUMIYA TAHARA, SEIYA FUKADA, AdSM, Hiroshima University — The mechanical exfoliation of graphite is possibly the simplest and practical method in laboratories to obtain graphene flakes for scientific research. However efficiency for obtaining graphene, with desired layer-number and size, depends largely on crystal specific characters, eg., dislocations. To improve the issue, we have adopted graphite intercalation compound (GIC) instead of graphite for a starting material. Generally, GIC is chemically active. We used SbCl_5 -GIC, which is stable in the atmosphere. Stage structure of SbCl_5 -GIC could be tuned by temperature of intercalation. We found that considerable number of undoped graphene flakes coexisted with thin SbCl_5 -GIC flakes, on a substrate where flakes were transferred. Statistical inspection of number of graphene layer indicated that it is significantly dependent on the stage number of GIC.

S1.00023 Graphene synthesis by calcination of ethylene-glycol intercalated layered silicates: x-ray and Raman scattering studies , NOBORU WADA, TOMOYA SUSA, Toyo University — Excellent electrical, mechanical and chemical properties of graphene make it fascinating for various applications including high-speed and high-performance electric devices. Although there have been many synthesis methods innovated to obtain graphene in the past, a simple and controllable synthesis method of graphene mass production is still being pursued for such applications. Here, layered silicates are chosen as a host material to intercalate ethylene glycol (EG). EG-intercalated layered silicates are then calcinated in air or vacuum to synthesize graphene between the silicate layers. Layered silicates used are taeniolite, fluorinated mica and vermiculite. Our Raman scattering and x-ray diffraction experiments suggest that graphene may be made between the silicate layers after calcination. In particular, second-order Raman peaks found in vermiculite samples indicate that vermiculite may be most suited to synthesize well-crystallized graphene among the layered silicates used.

S1.00024 AFM and SThM Characterization of Graphene , CHRISTOPHER FOY, ANTON SIDOROV, XUNCHI CHEN, MING RUAN, CLAIRE BERGER, WALTER DE HEER, ZHIGANG JIANG, Georgia Inst of Tech — We report on detailed characterization of epitaxial grown graphene on SiC and chemical vapor deposition grown graphene on Cu foil using atomic force microscopy (AFM) and scanning thermal microscopy (SThM). We focus on the electronic and thermal properties of graphene grain boundaries, and thus providing valuable feedback to materials growth. Specifically, we perform thermal conductivity contrast mapping and surface potential mapping of graphene, and compare with that obtained on the Au electrodes and the substrate.

S1.00025 Wafer-scale synthesis of defect-negligible monolayer graphene at reduced temperature on hydrogen-rich evaporated (111) copper films¹ , LI TAO, MILO HOLT, HARRY CHOU, JONGHO LEE, RODNEY S. RUOFF, DEJI AKINWANDE, The University of Texas at Austin — In contrast to commercially available copper foils, evaporated copper film on wafer scale supporting substrates holds great promise in chemical vapor deposition (CVD) of graphene for direct integration into device manufacturing processes. Monolayer graphene with negligible defects (<5%) was synthesized on evaporated copper films at temperatures < 900 °C using hydrogen-free methane precursor that has not been previously reported. In this work, high-quality monolayer graphene obtained on evaporated copper film was likely enabled by the distinct properties of hydrogen-rich (111) preferred crystal orientation as indicated by X-ray diffraction (XRD) and electron back scattering diffraction (EBSD). The distinct difference in the crystal orientation of copper films versus foils resulted in dissimilar interplay with the precursor gas, as confirmed by time-of-flight secondary ion mass spectroscopy (TOF-SIMS). This study demonstrates experimental evidence for differences in the growth dynamics of CVD graphene on copper film versus conventional foils.

¹Support of our work from ONR is appreciated.

S1.00026 Anisotropic Hydrogen Etching of Chemical Vapor Deposited Graphene, YI ZHANG, ZHEN LI, LUYAO ZHANG, PYOJAE KIM, CHONGWU ZHOU, University of Southern California — In terms of the preparation of graphene, chemical vapor deposition (CVD) has raised its popularity as a scalable and cost effective approach for graphene synthesis. While the formation of graphene on copper foil has been intensively studied, the reverse reaction of graphene reacts with hydrogen has not been systematically studied. In this talk we will present a simple, clean, and highly anisotropic hydrogen etching method for CVD graphene catalyzed by the copper substrate. By exposing CVD graphene on copper foil to hydrogen flow around 800 °C, we observed that the initially continuous graphene can be etched to have many hexagonal openings. In addition, we found that the etching is temperature dependent and the etching of graphene at 800 °C is most efficient and anisotropic. 80% of the angles of graphene edges after etching are 120°, indicating the etching is highly anisotropic. No increase of D band along the etched edges indicates that the crystallographic orientation of etching is zigzag direction. Furthermore, we observed that copper played an important role in catalyzing the etching reaction, as no etching was observed for graphene transferred to Si/SiO₂ under similar conditions. This highly anisotropic hydrogen etching technology may work as a simple and convenient way to determine graphene crystal orientation and grain size, and may enable the etching of graphene into nanoribbons for electronic applications.

S1.00027 Density functional theory calculations on the effects of oxygen adsorption on graphene in the presence of defects, FAISAL MEHMOOD, WEIJIE LU, JOHN J. BOECKL, RUTH PACTHER, Air Force Research Laboratory, Materials & Manufacturing Directorate, Wright-Patterson Air Force Base, Ohio 45433 — Density functional theory calculations were carried out to investigate effects of oxygen adsorption on the electronic and optical properties of single layer graphene (SLG) in the presence of defects. Stone-Wales and single and double vacancy defects, also including the 555-777 and 5555-6-7777, were considered. Analysis of changes upon oxygen adsorption will be reported in detail, regarding morphology, binding energies and electronic structure, as compared to pristine SLGs, for pure GGA, hybrid and van der Waals corrected functionals. Nudged elastic band calculations of various pathways were investigated in order to understand the diffusion and dissociation of oxygen on SLGs in the presence of defects. Calculation of the optical response carried out at different levels of theory will be discussed, using both hybrid and long-range corrected hybrid functionals, with consideration of comparison to experimental characterization. Finally, implications of the effects of oxygen adsorption on graphene in the presence of defects for aspects of catalyst-free growth or electron transport will be suggested.

S1.00028 Using the G' Raman cross-section to understand the phonon dynamics in bilayer graphene systems, DANIELA MAFRA, Universidade Federal de Minas Gerais, PAULO ARAUJO, Massachusetts Institute of Technology, KENTARO SATO, RIICHIRO SAITO, Tohoku University, MILDRED DRESSELHAUS, JING KONG, Massachusetts Institute of Technology — The integrated area (IA) of the four peaks (P₁₁, P₁₂, P₂₁ and P₂₂) of the G' Raman band of AB stacked bilayer graphene are analyzed as a function of the laser power for different laser lines. We show that the IA of each peak depends on temperature and also depends on the laser excitation energy. This special dependence is explained in terms of the electron-phonon coupling and the relaxation time of the photon-excited electron. Due to the short relaxation time of the photo-excited electron by emitting phonons, the relative intensities of the four peaks are determined by a different combination of relaxation processes that give rise to some G' peaks increasing in IA at the expense of others, thereby making the IA of the peaks different from each other and dependent on laser excitation energy and power level. Also, we report an anomalous behavior of the G' IA for the 532 nm laser energy, that shows a resonance regime in which a saturation of what we call the P₁₂ process occurs. This effect is a relevant phenomenon that gives important information about the electron and phonon dynamics and needs to be taken into account for certain applications of bilayer graphene in the field of nanotechnology.

S1.00029 Adhesive interaction between graphene membranes and amorphous substrates, RUI HUANG, WEI GAO, University of Texas at Austin — To integrate graphene in functional devices, it is essential to understand interfacial adhesion between graphene and surrounding materials for mechanical support and encapsulation. In complement with recent efforts aiming to measure the adhesion energy experimentally, we present a theoretical model for adhesive interaction between a graphene monolayer and an amorphous substrate. The model is extended to analyze the morphological stability of a graphene membrane on an oxide substrate. It is found that the bending modulus, which increases drastically from monolayer to multilayered graphene, plays an important role in the transition from conformal to non-conformal morphology of the graphene membranes on a corrugated surface. Furthermore, the work of adhesion is predicted to drop considerably from monolayer to bilayer graphene, in good agreement with recent measurements. The theoretical results suggest that tunable adhesion of graphene can be achieved by controlling the surface roughness of the substrate.

S1.00030 Structural Properties of Epitaxial Graphenes on 4H-SiC(0001): A Theoretical Study¹, MING YU, PAUL DAVIS, MICHAEL WOODCOX, C.S. JAYANTHI, S.Y. WU, University of Louisville — The structural properties of the epitaxial graphene including the buffer layer on 4H-SiC(0001) are studied using the recently developed SCED-LCAO molecular dynamics scheme [PRB 74, 15540 (2006)]. Both Si-terminated and C-terminated SiC substrates are considered. In a previous work [BAPS, Vol. 56, 463 (2011)], we had shown that 10x10 monolayers of carbon on 8x8 4H-SiC(0001) substrate as well as 13x13 monolayers of carbon on 6√3x6√3 4H-SiC(0001) substrate are minimum in strain between the buffer layer and the substrate and that they are nearly commensurate. In this work, we have added an epitaxial layer of graphene to the above geometries and both C-terminated and Si-terminated SiC surfaces will be considered. We will highlight the roles played by the buffer layer, the epitaxial layer, and the substrate on the structural properties of this system. Analysis of the structure in terms of local bonding arrangements and charge distributions will also be provided.

¹Acknowledgment: This work is supported by the Research Corporation (RC19902).

S1.00031 Intercalation of metal islands and films at the interface of epitaxially grown graphene and Ru(0001) surfaces¹, LI HUANG, YI PAN, LIDA PAN, MIN GAO, WENYAN XU, YANDE QUE, HAITAO ZHOU, YELIANG WANG, SHIXUAN DU, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM — Epitaxial graphene on Ru(0001) provides a high quality adlayer, but has a strong interaction with the substrate. This interaction can be effectively weakened via intercalating a layer of other element between epitaxial graphene and its substrate. In this work, we intercalated seven kinds of metals including noble metals Pt, Pd and Au, magnetic metals Ni and Co, a IIIA group metal In and a rare earth metal Ce, at the interface of epitaxially grown graphene and Ru(0001), to show the universality of metal intercalations in this system. These metals form different intercalated structures that have different impacts on the corrugation of graphene. Atomic resolution images of a perfect graphene lattice on the intercalated structures can always be obtained, which confirms that the intercalation of these metals is a non-damaging process. Additionally, based on primary DFT calculations, we propose a model involving metal-atom-aided-defect and self-healing of C-C bonds at high temperature, which can well explain the intercalation process of some metals and provide the potential to better understand the intercalation mechanism.

S1.00032 Superconductivity in Graphene-Lithium Systems¹ , DAVID GUZMAN, RADI AL-JISHI, Department of Physics and Astronomy, California State University - Los Angeles, HAMAD ALYAHYAEI, Department of Physics and Astronomy, University of California - Riverside — We present first-principles calculations on systems consisting of a few layers of graphene and lithium. In particular, we investigate the evolution of the electron-phonon coupling strength with an increasing number of layers. We find that for intercalated systems such as C₆-Li-C₆ or C₆-Li-C₆-Li-C₆ the electron-phonon coupling is weak. However, for systems of equal number of graphene and lithium layers, such as C₆-Li or C₆-Li-C₆-Li, the electron-phonon coupling is strong. We investigate the optimal configuration that yields the highest superconducting transition temperature.

S1.00033 ABSTRACT WITHDRAWN —

S1.00034 ABSTRACT WITHDRAWN —

S1.00035 Impermeable “single-monolayer” Graphenic encasement of bacteria for high vacuum Transmission electron microscopy¹ , BALABALAJI PADAVALA, PHONG NGUYEN, JOSHUA PODREBARAC, JENAE TATE, VIKAS BERRY, Kansas State University — Biological cells are hygroscopic, permeable, and electron-absorbing, and imaging them *via* electron microscopes has been an important challenge due to the volumetric-shrinkage and structural degradation of cells under high vacuum and fixed electron beam. In this talk, we will show that “single-monolayer” graphenic encasement of individual whole “wet” bacterial cells can enable wet-phase TEM imaging by preserving their dimensional, topological characteristics and cellular water under high vacuum (10⁻⁵ Torr) and beam current (150 A/cm²). Ultrathin and impermeable “single monolayer” graphene microsheet was wrapped around or laid on bacteria. The combination of strongly-packed honeycomb-lattice, high Young’s modulus, high electrical and thermal conductivity, and mesoscale flexibility of the single graphene monolayer reduced the permeability of cells under TEM conditions, significantly abated electron beam damage and cell-delamination from substrate.

¹KSU-Startup

S1.00036 η^6 Chemical Modification of Epitaxial Graphene: An Avenue for Non Destructive Surface Functionalization and Atomic Layer Deposition , PHONG NGUYEN, VIKAS BERRY, KABEER JASUJA, Kansas State University — Graphene’s superior properties are expected to develop next generation electronic applications. However, a major challenge which still remains is to incorporate it into different systems via its functionalization. Moreover, such functionalization must not alter graphene’s superior properties. In most cases, functionalization leads to conversion of the planar sp² hybridized state of carbon into the tetrahedral sp³ states. This conversion leads to an increase in carrier-scattering and a reduction in carrier-density. In this talk, we demonstrate a novel η^6 functionalization route, where the d-orbital of a transition metal binds with the pi-cloud at the center of graphene’s aromatic rings resulting in a unique grafting of a monolayer of metal atoms. As a result, the sp² state of the carbon atoms is preserved and its superior properties (high carrier density and low carrier scattering) are maintained. We envision that this functionalization route will allow graphene to be interfaced with several systems, thus significantly broadening the scope of its applications.

S1.00037 A three-dimensional architecture of vertically aligned multilayer graphene facilitates heat dissipation across joint solid surfaces , QIZHEN LIANG, XUXIA YAO, WEI WANG, C.P. WONG, Georgia Institute of Technology — Low operation temperature and efficient heat dissipation are important for device life and speed in current electronic and photonic technologies. Being ultra-high thermally conductive, graphene is a promising material candidate for heat dissipation improvement in devices. In the application, graphene is expected to be vertically stacked between contact solid surfaces in order to facilitate efficient heat dissipation and reduced interfacial thermal resistance across contact solid surfaces. However, as an ultra-thin membrane-like material, graphene is susceptible to Van der Waals forces and usually tends to be recumbent on substrates. Thereby, direct growth of vertically aligned free-standing graphene on solid substrates in large scale is difficult and rarely available in current studies, bringing significant barriers in graphene’s application as thermal conductive media between joint solid surfaces. In this work, a three-dimensional vertically aligned multilayer graphene architecture is constructed between contacted Silicon/Silicon surfaces with pure Indium as a metallic medium. Significantly higher equivalent thermal conductivity and lower contact thermal resistance of vertically aligned multilayer graphene are obtained, compared with those of their recumbent counterpart. This finding provides knowledge of vertically aligned graphene architectures, which may not only facilitate current demanding thermal management but also promote graphene’s widespread applications such as electrodes for energy storage devices, polymeric anisotropic conductive adhesives, etc.

S1.00038 Ballistic Transport in Graphene pnp Junctions Formed by Embedded Local Gates , SEUNG-GEOL NAM, DONG-KEUN KI, Department of Physics, Pohang University of Science and Technology, Pohang, Korea, JONG-WAN PARK, Technology Development Team, National NanoFab Center, Korea, YOUNGWOOK KIM, JUN-SUNG KIM, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, Pohang, Korea — Due to its gapless energy spectrum, one enables to tune the carrier type and density in graphene and realize pnp-type potential barriers in situ by using electrostatic gating. Such potential barriers provide opportunities to investigate novel phenomena such as Klein tunneling and quantum-Hall edge-state equilibration. In this study, we obtained high-quality graphene pnp junctions by embedding pre-patterned local gates in a substrate without dielectric-layer deposition or electron-beam exposure of the graphene sheet. We achieved ballistic and phase-coherent carrier transport in a graphene pnp device with a 130-nm-wide local gate, which is almost an order magnitude wider than reported previously[1]. In a high magnetic field, device with a 1-micro meter-wide local gate exhibited the $2e^2/h$ quantum-Hall plateau, indicating no backscattering in the local gate region. The conductance across our pnp junctions shows a gate-voltage dependence that is very distinctive from that of top-gated junctions, indicating a strong screening of the electric field by the embedded local gate. S1.00039 Carbon Nucleation from ring seeds on Icosahedral Fe₁₃¹ , ANTENEH TEFERA, MOGUS MOCHENA, Florida A&M University — Using ab initio molecular dynamics calculation, we computed the initial stages of carbon nanotube growth from ten – atom carbon rings on icosahedral Fe₁₃. The carbon ring interacts with Fe₁₃ to form a zigzag structure due to a mismatch between the number of atoms on the ring and the atoms on the pentagonal ring of Fe₁₃, with formation energy of 2.2 eV. A mixture of carbon dimers and carbon atoms interact with the Fe₁₃ + C₁₀ structure to yield a tubular structure with the lowest energy. Another configuration of carbon atoms distributed in the vicinity hexagonal lattice sites interacts with Fe₁₃ + C₁₀ structure to form also a tubular structure that is almost degenerate in energy to the ground state. The results indicate that the icosahedral symmetry of the Fe₁₃ with its magnetic moment almost intact is retained whenever the tubular structure is formed.

S1.00040 Anomalous dependence of band gaps of binary nanotubes on diameters¹, KAPIL ADHIKARI, MUHAMMAD HUDA, ASOK RAY, Department of Physics, University of Texas at Arlington — Using cluster approximation, AlN, BN, GaN, SiGe, SiC, and GeC armchair type 1 nanotubes have been spin optimized using the hybrid functional B3LYP, a double ζ basis set and the GAUSSIAN 03 software. The electronic structures of group III nitride and group IV-IV nanotubes indicate that the band gap increases with tube diameter contrary to behavior expected from quantum size effects. A detailed study indicates that, in a class of binary nanotubes with partial ionic contributions in the bonds, for example, AlN, BN, GaN, GeC, and SiC, ionicity of the bonds decreases as diameter decreases due to increased sp^3 contribution. This causes the band gap to increase with diameter. But in nanotubes with covalent bonding, for example SiGe, the gap decreases with diameter. A general trend for a class of binary nanotubes is established.

S1.00041 Ultra high Transparent and Conductive Electrodes Based on As-Grown SWNT with Metallic Conductivity, TEREZA PARONYAN, ELENA PIGOS, GUGANG CHEN, AVETIK HARUTYUNYAN, Honda Research Institute USA Inc., Columbus, OH, 43212, USA, HONDA RESEARCH INSTITUTE USA INC. TEAM — Carbon based materials have been proven to be a unique material for transparent conducting films, with potential for application on liquid crystal displays, touch screens and solar cells. We successfully grew SWNT films by Chemical Vapor Deposition method using Fe nanocatalysts on quartz substrates. The ratio of semiconductor/metallic nanotubes varied depending on the treatment conditions of the catalyst nanoparticles, according to Raman analysis. SEM analysis of the samples revealed homogeneous coverage of the quartz substrates by SWNTs, which exhibit transparencies higher than 98%. Sheet resistance measurements of these SWNT films, by Van der Pauw method, demonstrated the correlation between the conductivity and the abundance of semiconductor and metallic nanotubes in the films. Increasing the content of metallic SWNTs in the film up to 90% decreased the sheet resistance down to 4-5 K Ω /, while maintaining a high transparency of over 98%. For comparison, transparent electrodes based on high quality monolayer graphene sheets were also fabricated. The conductivity and transparency of the electrodes of as grown SWNTs were comparable to the electrodes based on monolayer graphene.

S1.00042 Determination of the vibration frequencies of Carbon Nanotubes and Carbon Nanoribbons¹, M. PACHECO, Universidad Federico Santa Maria, A. LEON, Universidad Diego Portales — The optical properties of organic materials are similar to the properties of the molecules that constitute it. This motivates the study of molecular complexes that would form new materials. Interesting optical properties are observed in conjugated polymers due to delocalized π electrons, which allow transitions in the visible spectrum. In this work we present results of the vibration spectrum for pristine and functionalized carbon nanoclusters. The electronic properties are obtained by first principles calculations, based on the Becke-Perdew GGA approximation. The frequencies are computed numerically by differentiation of the energy gradients in slightly displaced geometries. The three stages of calculations will be performed using the ADF code. The geometric optimization protocols for pristine and functionalized structures are made adopting the “quasi Newton approach.” The vibration spectra show interesting properties when the structures are functionalized with organic molecules.

S1.00043 High surface area electrode for high efficient microbial electrosynthesis, HUARONG NIE, Department of Polymer Science & Engineering, University of Massachusetts, Amherst, MENG MENG CUI, HAIYUN LU, Department of Polymer Science & Engineering, University of Massachusetts, Amherst, TIAN ZHANG, Department of Microbiology, University of Massachusetts, Amherst, THOMAS RUSSELL, Department of Polymer Science & Engineering, University of Massachusetts, Amherst, DEREK LOVLEY, Department of Microbiology, University of Massachusetts, Amherst — Microbial electrosynthesis, a process in which microorganisms directly accept electrons from an electrode to convert carbon dioxide and water into multi carbon organic compounds, affords a novel route for the generation of valuable products from electricity or even wastewater. The surface area of the electrode is critical for high production. A biocompatible, highly conductive, three-dimensional cathode was fabricated from a carbon nanotube textile composite to support the microorganism to produce acetate from carbon dioxide. The high surface area and macroscale porous structure of the intertwined CNT coated textile ?bers provides easy microbe access. The production of acetate using this cathode is 5 fold larger than that using a planar graphite electrode with the same volume. Nickel-nanowire-modified carbon electrodes, fabricated by microwave welding, increased the surface area greatly, were able to absorb more bacteria and showed a 1.5 fold increase in performance

S1.00044 In-Air Growth of Carbon Nanoflowers¹, CHRISTOPHER HUYNH, RYAN LU, KIMI CSANADI, AYAX RAMIREZ, SPAWAR SYS CEN PAC, DEBJYOTI BANERJEE, Texas AM University — A new class of carbon nanostructures was fabricated under rapid heating in air. Solid carbon sources and metal catalysts were used to facilitate growth. Their microstructures were characterized using scanning electron microscopy and micro Raman spectroscopy. The results indicate patches of graphene and carbon tapered tubules. Two methods of fabrication are presented.

¹Supported by ONR

S1.00045 A Molecular Dynamics Study on the Confinement of Carbon Dioxide Molecules in Carbon Nanotubes¹, MEAGAN LAZOR, DENIZ RENDE, NIHAT BAYSAL, RAHMI OZISIK, Rensselaer Polytechnic Institute — The influence of atmospheric carbon dioxide (CO₂) concentration on global warming is considered as one of the primary environmental issues of the past two decades. The main source of CO₂ emission is human activity, such as the use of fossil fuels in transportation and industrial plants. Following the release of Kyoto Protocol in 1997, effective ways of controlling CO₂ emissions received much attention. As a result, various materials such as activated carbon, zeolites, and carbon nanotubes (CNTs) were investigated for their CO₂ adsorbing properties. CNTs were reported to have CO₂ adsorption capability twice that of activated carbon, hence they received the most attention. In the current study, single walled carbon nanotubes (SWNTs) were used as one dimensional nanoporous materials and their CO₂ adsorption capacity was analyzed with Molecular Dynamics simulations. Results indicated that SWNTs are excellent CO₂ adsorbers and their effectiveness increase at low CO₂ concentrations. In addition, we showed that by varying temperature, CO₂ can be removed from the SWNTs, providing a simple method to reuse SWNTs.

¹Partial support was provided by NSF Grant No. 1003574 and RPI. DR is also supported by TUBITAK 2219 program.

S1.00046 A Molecular Dynamics Study on the Exfoliation of Single Walled Carbon Nanotubes in Supercritical Carbon Dioxide¹, SEMRA SENTURK-OZER, Stevens Institute of Technology, DENIZ RENDE, NIHAT BAYSAL, RAHMI OZISIK, Rensselaer Polytechnic Institute — Carbon nanotubes (CNTs) could be used in various technological applications due to their structural, electrical and mechanical properties. However, in order to get the theoretically predicted benefits, nanotubes have to be successfully dispersed in the polymer matrix. Supercritical fluids were previously shown to result in good dispersion of nanofillers (in the case of clays and spherical nanofillers). In the current study, we investigated the potential use of supercritical carbon dioxide to unbundle single walled carbon nanotubes via molecular dynamics simulations. Various carbon nanotube systems were simulated with XenoView simulation software, and the effect of surface modification of nanotube with CO₂-philic chemicals was investigated on nanotube dispersion. Results showed that surface modification of nanotubes improves their dispersion in supercritical carbon dioxide.

¹Partial support was provided by NSF Grant No. 1003574 and RPI. DR is also supported by TUBITAK 2219 program.

S1.00047 Interplay of Wetting and Elasticity in the Nucleation of Carbon Nanotubes , DMITRI SCHEBARCHOV, SHAUN C. HENDY, Industrial Research Ltd., ELIF ERTEKIN, University of Illinois, JEFFREY C. GROSSMAN, Massachusetts Institute of Technology — Controlling the structure of single-walled carbon nanotubes during synthesis is one of the outstanding challenges of nanoscale science. Some degree of control has been demonstrated through catalytic synthesis, where the interaction with the catalyst is believed to play a key role, but the exact mechanisms leading to preferential growth remain unclear. Here we report on the development of a model that focuses on the lift-off of carbon nanotube caps after nucleation. We test the model using atomistic molecular dynamics simulations and discuss the implications of the model for understanding growth processes that may control chirality. We illustrate the role of the competition between cap strain energy and adhesive forces in the lifting of these caps from the catalyst surface prior to elongation. We show that, given a particular cap structure, there is a lower bound on the catalyst size from which the cap can lift. This lower bound explains the mismatch between nanotube and catalyst diameters observed in experiment. These findings offer new insight into the nucleation of single-walled carbon nanotubes, and they may lead to the design of catalysts that can better control nanotube structure.

S1.00048 Electronic properties of carbon nanodisks and nanocones , ANDREA LATGE, Instituto de Física, UFF, Niterói-RJ, Brazil, PABLO ULLOA, MONICA PACHECO, Departamento de Física, UTFSM, Valparaíso, Chile, LUIZ EDUARDO OLIVEIRA, Instituto de Física, UNICAMP, Campinas-SP, Brazil — The electronic properties of graphene nanodisks and nanocones are calculated following a tight-binding approach. The total density of states of both structures are found to be quite similar when a large number of atoms is considered, including the peak at the Fermi energy associated with the contribution of the border atoms. We have also calculated, for both systems, the local density of states which highlight the differences of the electronic structures due to the particularities of the spatial symmetry of the nanodisks and nanocones. Moreover, the electronic properties are thoroughly discussed via the analysis of the joint density of states and absorption spectra of the nanostructures.

S1.00049 Synthesis and field emission properties of periodic arrays of vertically aligned carbon nanotubes on copper¹ , SUMAN NEUPANE, WENZHI LI, Florida International University — Periodic arrays of carbon nanotubes (CNTs) with different densities were synthesized on copper substrate by employing nanosphere lithography (NSL) and plasma enhanced chemical vapor deposition. Vertically aligned CNTs were formed using Ni as catalyst at a growth pressure of 8 torr of C₂H₂/NH₃ mixture and a temperature of 520 °C. Electron emissions of the CNTs with different densities were investigated to reveal the dependence of the electron emission properties of the CNTs on their densities. Experimental results showed that low-density CNTs exhibited better field emission properties as compared to the high-density CNTs. Low-density CNTs exhibited lower turn-on and threshold electric fields, and a higher field enhancement factor. The high density of CNTs resulted in the deterioration of the FE properties due to the screening of the electric field by the adjoining CNTs.

¹This work is supported by the National Science Foundation under the grant DMR-0548061

S1.00050 Fabrication of Micro-Electromagnetic Devices for the Manipulation of Carbon Nanotubes , JOHN BRIDSTRUP, ANTHONY SPEZIALE, SCOTT PAULSON, James Madison University — With advances in microscopy techniques, such as transmission electron and scanning transmission electron microscopy, it has become increasingly more interesting to study and manipulate the structures of solid state materials at the atomic scale. One of the issues with the study of these properties is that these advanced microscopes require that the sample be confined to a space not very conducive to traditional methods of actuation, such as atomic force microscopy and electrostatic methods. In our research, we are primarily focused on building tiny “electro-magneto-mechanical” devices on carbon nanotubes in order to manipulate them without breaking vacuum or removing them from the microscope. Our current project is focused on putting small, magnetizable paddles on to the carbon nanotubes, using an SEM for electron beam lithography and a metal evaporation deposition system, then running current to induce a magnetic field with which the paddles, which can have any magnetic dipole we want, will align. In order to create these devices we must first choose a type of material and a method for creating the magnetic paddles, in our work we use iron. The main problem with iron is the rate at which it oxidizes at the nanoscale, it is practically instantaneous. Because of this we have developed a method, using what basically amounts to simple geometry, for encasing our iron paddles with gold and thus preventing the oxidation. It is our hope that this research opens the doors for many new opportunities in nanoscale materials science, and at the least greatly reduce the time required for many current experiments.

S1.00051 2D Fluidization of Nanomaterials by Biomimetic Membranes , KATHLEEN KELLY, MARTIN FORSTNER¹, Physics Department, Syracuse University, Syracuse, NY, 13244 — The last decade has seen much progress in the synthesis and manufacturing of a large variety of nanometer sized particles of different materials, geometries and properties. If they can be assembled into larger structures, these manmade nano-objects are posed to be the “atoms” and “molecules” of new materials. In order to facilitate their dynamic rearrangements we have developed a method that uses material specific binding peptides to anchor nano-objects to lipids in supported bilayers (SLB). In this study we use single walled carbon nanotubes (CNT) with a mean length of 1 micrometer as model of a potential nano-building block. By fluorescently labeling CNTs we are able to use video-microscopy to investigate the dynamic behavior of membrane anchored CNTs. We show that the 2D fluidity of the lipid membrane can be successfully templated on the CNTs and that they stay laterally mobile while being confined to a plane. Furthermore, the dependence of CNT mobility on specific binding stoichiometries is discussed.

S1.00052 SWNT Imaging Using Multispectral Image Processing , MICHAEL BLADES, MASSOOMA PIRBHAI, SLAVA V. ROTKIN, Lehigh University — A flexible optical system was developed to image carbon single-wall nanotube (SWNT) photoluminescence using the multispectral capabilities of a typical CCD camcorder. The built in Bayer filter of the CCD camera was utilized, using OpenCV C++ libraries for image processing, to decompose the image generated in a high magnification epifluorescence microscope setup into three pseudo-color channels. By carefully calibrating the filter beforehand, it was possible to extract spectral data from these channels, and effectively isolate the SWNT signals from the background.

S1.00053 Absorption of Carbon Monoxide Molecules On Carbon Nanotubes¹ , LIANGBO LIANG, VINCENT MEUNIER, Rensselaer Polytechnic Institute — Carbon nanotubes (CNTs) have been demonstrated to be promising nanoscale molecular sensors for detecting gas molecules such as NH₃, NO₂ and O₂. But pristine CNTs show limitations in detection of highly toxic gases such as carbon monoxide (CO). In our work, interaction of CO molecules with both armchair and zigzag single-walled CNTs (SWCNTs) has been investigated through Density Functional Theory (DFT) simulations using the software VASP. SWCNTs with structural deformation, Stones-Wales (SW) defects or single vacancy (SV) defects are considered. It has been found that structural deformation, resulting in the significant change of local physical properties, enables strong chemical absorption of CO molecules on the surface of CNTs. In addition, a SV defect also brings about dramatic change in the local geometrical structure and higher chemical reactivity, facilitating strong binding of one and two CO molecules on CNTs. Compared to pristine and SW-defect CNTs, deformed and SV-defect CNTs are more promising as gas sensors to detect toxic carbon monoxide molecules.

S1.00054 Van der Waals Interactions of Organic Molecules on Semiconductor and Metal Surfaces: a Comparative Study¹, GUO LI, Institute of Physics, CAS, China; ICQD/HFNL, USTC, China, VALENTINO COOPER, Oak Ridge National Lab, JUN-HYUNG CHO, Hanyang University, Korea, ISAAC TAMBLYN, Lawrence Berkeley National Lab, SHIXUAN DU, Institute of Physics, CAS, China, JEFFREY NEATON, Lawrence Berkeley National Lab, HONG-JUN GAO, Institute of Physics, CAS, China, ZHENYU ZHANG, ICQD/HFNL, USTC, China; Harvard University — We present a comparative investigation of vdW interactions of the organic molecules on semiconductor and metal surfaces using the DFT method implemented with vdW-DF. For styrene/H-Si(100), the vdW interactions reverse the effective intermolecular interaction from repulsive to attractive, ensuring preferred growth of long wires as observed experimentally. We further propose that an external E field and the selective creation of Si dangling bonds can drastically improve the ordered arrangement of the molecular nanowires [1]. For BDA/Au(111), the vdW interactions not only dramatically enhances the adsorption energies, but also significantly changes the molecular configurations. In the azobenzene/Ag(111) system, vdW-DF produces superior predictions for the adsorption energy than those obtained with other vdW corrected DFT approaches, providing evidence for the applicability of the vdW-DF method [2].

S1.00055 Analyzing the frequency shift of physi-adsorbed CO₂ in metal organic framework materials¹, YANPENG YAO, Rutgers, The state university of New Jersey, NOUR NIJEM, University of Texas at Dallas, JING LI, Rutgers, The state university of New Jersey, YVES CHABAL, University of Texas at Dallas, DAVID LANGRETH, Rutgers, The state university of New Jersey, TIMO THONHAUSER, Wake Forest University — Combining first-principles density functional theory simulations with IR and Raman experiments, we determine the frequency shift of vibrational modes of CO₂ when physi-adsorbed in the iso-structural metal organic framework materials Mg-MOF74 and Zn-MOF74. Surprisingly, we find that the resulting change in shift is rather different for these two systems and we elucidate possible reasons. We explicitly consider three factors responsible for the frequency shift through physi-absorption, namely (i) the change in the molecule length, (ii) the asymmetric distortion of the CO₂ molecule, and (iii) the direct influence of the metal center. The influence of each factor is evaluated separately through different geometry considerations, providing a fundamental understanding of the frequency shifts observed experimentally.

¹This work is support by DoE.

S1.00056 Zinc in +III oxidation state, DEVLEENA SAMANTA, PURU JENA, Virginia Commonwealth University — The possibility of Group 12 elements, such as Zn, Cd, and Hg existing in an oxidation state of +III or higher has fascinated chemists for decades. Significant efforts have been made in the past to achieve higher oxidation states for the heavier congener mercury (since the 3rd ionization potential of the elements decrease as we go down the periodic table). It took nearly 20 years before experiment could confirm the theoretical prediction that Hg indeed can exist in an oxidation state of +IV. While this unusual property of Hg is attributed to the relativistic effects, Zn being much lighter than Hg has not been expected to have an oxidation state higher than +II. Using density functional theory we show that an oxidation state of +III for Zn can be realized by choosing specific ligands with large electron affinities i.e. superhalogens. We demonstrate this by a systematic study of the interaction of Zn with F, BO₂, and AuF₆ ligands whose electron affinities are progressively higher, namely, 3.4 eV, 4.4 eV, and 8.4 eV, respectively. Discovery of higher oxidation states of elements can help in the formulation of new reactions and hence in the development of new chemistry.

S1.00057 A multi-scale model using single ion impacts predicts large-scale pattern formation in irradiated solids, SCOTT NORRIS, Southern Methodist University — Energetic particle irradiation of solids can lead to highly regular nanoscale pattern formation under the right environmental conditions. The widespread use of this technology in current industrial settings for doping and hardening suggests the promise of harnessing spontaneous pattern formation to create novel devices. However, existing theoretical models of ion irradiation fail to agree broadly with experiment even in the linear regime of small-amplitude patterns. A central challenge in modeling this system is to rigorously connect the pico-second effect of single ion impacts, spanning mere nanometers of material, to the long-time evolution of surface structures spanning tens to hundreds of nanometers. Here, we present a multi-scale framework that achieves this end. We start with molecular dynamics simulations of single ion impacts, and upscale this data into a continuum PDE for the surface topography. Stability analysis of the PDE predicts the characteristic pattern wavelength as the incidence angle is varied. The predictions agree remarkably well with experiment, and overturn the long-held assumption that pattern formation is due to the removal of target atoms by sputter erosion.

S1.00058 Multiscale atomistic and coarse-grained-particle analysis of fracture of graphene sheet, RYO KOBAYASHI, TAKAHIDE NAKAMURA, SHUJI OGATA, Nagoya Institute of Technology — The problems related to material strength such as crack propagation, dislocation motion, and response to nano-indentation involve multiscale phenomena which atomistic or non-linear events occur at a certain confined region and elastic or linear deformation takes place at surrounding wide-spread region. In order to tackle these multiscale problems, we have developed the hybrid molecular-dynamics/coarse-grained-particle (MD-CGP) method which eliminates the artificial effects often occurred at the interface of atomistic and coarse regions by using extra atoms and particles at the interface and applying the Langevin thermostat for the extra atoms and particles. The method allows us to perform multiscale simulations of any materials such as metals, semiconductors, and insulators and of dynamic phenomena at finite-temperatures. We have performed the multiscale simulation of fracture of defect-free graphene membrane by nano-indentation and clarified that decrease of the fracture strength with respect to temperature is almost same as that by existence of a vacancy. We will discuss detail about the computational efficiency of this method and simulation results.

S1.00059 Interface magnetism in LSMO-BiFeO₃ heterostructures, DIPANJAN MAZUMDAR, Center for Materials for Information Technology, University of Alabama, CECILIA SANCHEZ HANKE, Advanced Light Source, Lawrence Berkeley National Lab, ARUNAVA GUPTA, Center for Materials for Information Technology, University of Alabama, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Lab, U ALABAMA TEAM, LBNL TEAM — The interplay of the magnetic and ferroelectric order parameter is currently a topic of intense research. This magnetoelectric coupling can potentially be enhanced at the interface of a FM-FE heterostructure and, therefore, study of such prototype interfaces could provide fundamental insight to design of multiferroic materials. In this work interface magnetism investigations of multiferroic BFO (3-5nm) with a high-spin polarization ferromagnet (LSMO, 10nm) is presented. We have performed detailed resonant reflectivity studies at the Mn (for LSMO) and Fe (for BFO) L₃ edges in LSMO/BFO as a function of temperature. Analysis of the data using rigorous scattering theory employing the tensor nature of the refractive index has elucidated the charge and magnetic density depth profiles along the depth of the film. Investigations at room temperature do not show magnetism at the Fe-edge which imply that the antiferromagnetic order in BFO persists both in bulk and interface. A comprehensive interface characterization as a function of temperature will be presented.

S1.00060 Designing Smart Surfaces to Segregate Cells , GERMAN KOLMAKOV, SAMDEN LAMA, FERNANDO HERNANDEZ, ERVIN IBRAGIMOV, New York City College of Technology CUNY, COLLIN EDINGTON, RICHARD KOEPEL, JILL ANDERSEN, DANIEL MCKEEL, McGowan Institute for Regenerative Medicine, University of Pittsburgh, SUNGEUN EOM, TAKEO KANADE, CARSEN KLINE, Carnegie Mellon University, ZVI LIRON, Israel Institute for Biological Research, HIRONOBU MURATA, ALAN RUSSELL, McGowan Institute for Regenerative Medicine, University of Pittsburgh, ANNA BALAZS, Chemical Engineering Department, University of Pittsburgh — Our aim is to utilize smart surfaces to separate specific populations of cells from a heterogeneous sample. There are a number of diseases (e.g., malaria and various cancers) that alter the elasticity of biological cells. In this work, we use the mechanical stiffness of the cells as a key parameter since it can reveal the presence of disease. By integrating mesoscale models for hydrodynamics of surrounding fluids and for micromechanics of cells, and the Hierarchical Bell Model for specific cell-substrate interactions, we examine the fluid-driven motion of cells in a microchannel over a hard, weakly adhesive surface that contains “sticky” diagonal stripes. We show that as cells roll along the surface, they obtain a net displacement perpendicular to the direction of the fluid flow. This displacement is a function of the cell’s stiffness, meaning that two cells with different compliances or adhesive properties exhibit different amounts of displacement, and in this manner are effectively sorted. We compare the results of the simulations with the data obtained in the experiments with HL-60 cells.

S1.00061 Biocompatibility of Carbon Nanotubes in Mammalian Cells: An Imaging Based Approach , HOWARD CHEN, Massachusetts General Hospital, Harvard Medical School, JESSICA LUCAS, Simmons College, HANNAH PONEK, CHRISTOPHER EVANS, BRADLY BAER, SARA CHOUNG, MICHELLE CHEN, Point Loma Nazarene University — Carbon nanotubes have been widely researched for ultrasensitive biomolecule detection and drug delivery. However, its impact on cells is yet to be fully characterized, mainly due to the complex biological in vivo environment. We report here a mammalian cell-imaging paradigm to study the cellular response to single-walled carbon nanotubes (SWNTs) at the single-cell level. Chinese Hamster Ovarian cells were exposed to SWNTs resuspended in phosphate buffered saline (PBS) at various concentrations. Upon exposure, we optically imaged the cells (1) to visually quantify the SWNTs’ crossing of the cell membrane in real-time; (2) to both qualitatively and quantitatively assess the morphological changes associated with cellular stress in the presence of SWNTs; and (3) to serially quantify cell survival with highly sensitive bioluminescence-based imaging. Consistent with literature reports, high concentration of SWNTs acutely compromised cell division and decreased cell survival. Low concentrations were well tolerated by the cells initially but had similar effects after prolonged exposure. We discuss the inter-relationships among the cell morphology, viability, and intracellular SWNT uptake parameters, as a function of nanotube concentration and exposure time.

S1.00062 Radial Distribution Function of Silicene¹ , MA. RAYO CHAVEZ-CASTILLO, Instituto de Fisica BUAP, MARIO ALBERTO RODRIGUEZ-MEZA, Depto. de Fisica, ININ, LILIA MEZA-MONTES, Instituto de Fisica BUAP — Silicene is the counterpart of graphene and its potential applications as a part of the current electronics, based in silicon, make it a very important system to study. We perform molecular dynamics simulations and analyze the structure of two and three dimensional arrays of Si atoms by means of the radial distribution function at different temperatures and densities. As a first approach, for the 2D case, the Lennard-Jones potential is used and two sets of parameters are tested. We found that the radial distribution function does not change with the parameters and resembles the corresponding to the (111) surface of the FCC structure, which is similar to that of the honeycomb lattice although with different peak heights. The liquid phase appears at very high temperatures, suggesting a very stable system in the solid phase. In 3D, a comparison with potentials developed specifically for silicon, as suggested by Stillinger and Weber[F. H. Stillinger and T. A. Weber, Phys. Rev. B 31, 5262 (1985)] will be presented.

¹Partially supported by CONACYT CB-133516 and VIEP-BUAP.

S1.00063 Electronic and transport properties of metallic hexaboride nanorods , LU WANG, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68132, DANIEL VALENCIA, JUN-QIANG LU, Department of Physics, University of Puerto Rico at Mayagüez, PR 00681, RENAT SABIRIANOV, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68132, CHIN LI CHEUNG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588 — In this work, we performed electronic structure calculations of quasi one-dimensional metallic hexaboride XB₆ nanorods, where X are mostly rare-earth metals with 4f levels such as La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, and Lu, which usually regarded as good thermoelectric materials because of their low work functions and transport properties. Our purpose is to facilitate the research and manufacture of metal boride probes, thus we study extensively the size-dependence and element-specificity of the electronic properties. In these nanorods, we uncovered few general features that elucidate their excellent thermionic and field emission property. To further investigate the transport properties, we adopted the combined Landauer-Buttiker formalism and non-equilibrium Green’s function technique to compute the transmission coefficients near the Fermi level and found that hexaboride nanorods can be converted from metallic to semiconducting by applying a gate voltage larger than 10 V.

S1.00064 Electronic transport in aperiodic nanosheets, nanotubes and nanowires¹ , VICENTA SANCHEZ, Departamento de Fisica, Facultad de Ciencias, Universidad Nacional Autonoma de Mexico., CHUMIN WANG, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico. — Based on the Kubo-Greenwood formula, we study the electronic transport in cubically-structured quasiperiodic nanosheets, nanotubes and nanowires, where the nanotubes are made by connecting one of the boundaries of a square-lattice sheet and the nanowires have a cross section of 90×90 atoms. Calculations of electrical conductivity were performed by using a tight-binding Hamiltonian and by combining the convolution theorem with the real-space renormalization method [1]. The *dc* conductance shows quantized spectra, where nanotubes have steps with a double height in comparison with those of a nanosheet, both in contrast to an inhomogeneous step structure derived from nanowires. The *ac* conductivity shows a Drude and an oscillating behavior, when the electric field is along a periodic or quasiperiodic direction, respectively. Finally, the theoretical results are compared with experimental data.

S1.00065 Trainable solar cell effect in TPPS4 nanowires.¹ , KATHERINE L. VAN AKEN, MARJON ZAMANI, IAN W. HALVIC, Haverford College, ZHENGQING J. QI, A.T. JOHNSON, University of Pennsylvania, WALTER F. SMITH, Haverford College — We have measured photovoltaic currents for self-assembled *meso*-tetra(4-sulfonato-phenyl)porphine (TPPS4) nanowires. This is surprising, given that our devices are symmetrical. However, by “training” the nanowires with a bias voltage, we can break this symmetry. After training, when the nanowires are illuminated with a 488 nm laser under zero bias voltage, a solar cell current is observed, with polarity opposite to the training voltage. The magnitude of solar cell current depends on both the time of training and the magnitude of the training voltage. After the training voltage is removed, the solar cell current decays very quickly initially and then transitions to a much slower decay. This suggests that there are different populations of trapped charges that are repositioned by the electric field of the training voltage, and that are responsible for the solar cell current. We present a qualitative model in which the Schottky barriers at the interfaces with electrodes are affected by these trapped charges, leading to asymmetrical charge transport and thus to the observed current.

S1.00066 Structural Properties and Stability of Double Walled Armchair Silicon Nanotubes¹

HAOLIANG CHEN, ASOK RAY, Physics Department, University of Texas at Arlington, Arlington, Texas 76019 — A systematic study of armchair double-walled Si nanotubes (DWNT) $(n,n)@(m,m)$ ($3 \leq n \leq 6$; $7 \leq m \leq 12$) using the finite cluster approximation is presented. The geometries of the tubes have been spin optimized with an all electron 3-21G* basis set and the B3LYP functional. The study indicates that the stabilities of the double-walled Si nanotubes are of the same order as those of single-walled Si nanotubes suggesting the possibilities of experimental synthesis of both single-walled and double-walled Si nanotubes. The binding energy per atom or the cohesive energy of the double-walled nanotubes depends not only on the number of atoms but also on the coupling of the constituent single-walled nanotubes. Some nanotubes with small interlayer separations do not hold the coaxial cylindrical structure after optimization. The NTS $(n, n)@(n+3, n+3)$ are found to have large formation energies and binding energies per atom. For example, $(3,3)@(6,6)$, $(4,4)@(7,7)$, $(5,5)@(8,8)$, and $(6,6)@(9,9)$ all have large binding energies per atom, around 3.7eV/atom. All double-walled Si nanotubes are found to be semiconductors. However, the band gap, in general, is observed to decrease from single walled nanotubes to double walled nanotubes.

S1.00067 Hierarchically driven nanostructure electrocatalysts for direct sensing of biomolecules

YUMIN LEE, JUN HO SHIM, MINKYUNG KANG, HYE SU JANG, Department of Chemistry & Nano Science, Ewha Womans University, JEONG MIN BAIK, School of Mechanical and Advanced Materials Engineering, Ulsan National Institute of Science and Technology, YOUNGMI LEE, CHONGMOK LEE, MYUNG HWA KIM, Department of Chemistry & Nano Science, Ewha Womans University — Applying nanoscale device fabrications toward biomolecules, ultra sensitive, selective, robust, and reliable chemical or biological microsenors have been one of the most fascinating research directions in our life science. It is still challenging to make miniaturized sensors having the sensitive detectability to biologically relevant species due to limitations in terms of catalytic efficiency and sustainability. We introduce hierarchically driven iridium dioxide nanowires (IrO_2 NWs) directly on a platinum (Pt) microwire, which allows a simple fabrication of the amperometric sensor and shows a favorable electronic property desired for sensing of H_2O_2 and NADH without aid of enzymes. We have prepared highly crystalline IrO_2 needlelike-NWs by an atmospheric pressure chemical vapor deposition of IrO_2 powder without catalyst on a Pt wire surface, IrO_2 NWs-Pt, which was tested as an amperometric microsensor. The structures and morphologies of the IrO_2 NWs were characterized using FE-SEM, HRTEM and Raman spectroscopy. This rational engineering of a nanoscale architecture based on the direct formation of the 1-D nanostructures on an electrode can offer a useful platform for high performance electrochemical biosensors efficiently, sensitive detection of biologically important molecules.

S1.00068 Hierachically grown RuO_2 nanowires on electrospun IrO_2 nanofiber

JAEEYON LEE, Department of Chemistry & Nano Science, Ewha Womans University, HEE-SUNG YANG, Department of Nano Science & Technology, Sejong University, YUKYUNG CHO, Department of Chemistry & Nano Science, Ewha Womans University, HAE-YOUNG SHIN, SEOKHYUN YOON, Department of Physics, Ewha Womans University, JEONG MIN BAIK, School of Mechanical and Advanced Materials Engineering, Ulsan National Institute of Science and Technology, YOUNG-SOO SEO, Department of Nano Science & Technology, Sejong University, MYUNG HWA KIM, Department of Chemistry & Nano Science, Ewha Womans University — Electrospinning is a well known tool to synthesize nanofibers with the various diameters. Iridium oxide(IrO_2) and Ruthenium oxide(RuO_2) have a great potential as materials for electrodes in electrochemical devices due to their high electrical conductivity, chemical stability, and characteristics. So when they are mixed, we expect superior electrochemical properties and stability. We synthesize IrO_2 nanofibers from mixture of Iridium precursor and polymer. At certain condition, we were able to obtain uniform and continuous fibers that the average diameter of nanofibers is approximately 150 nm. After calcination, RuO_2 nanowires were then hierarchically grown on IrO_2 nanofibers by APCVD at about 650 ° without any catalyst. The diameters of nanowires are about 50 nm and the length is $\sim 1.5 \mu\text{m}$. The structures and morphologies were examined using scanning electron microscopy (FE-SEM), high resolution electron microscopy (HRTEM), X-ray diffraction (XRD) spectrum and Raman spectroscopy.

S1.00069 Synthesis of metallic ReO_3 nanowires

DONGSHIN MYUNG, Department of Chemistry & Nano Science, Ewha Womans University, JEONG MIN BAIK, School of Mechanical and Advanced Materials Engineering, Ulsan National Institute of Science and Technology, MYUNG HWA KIM, Department of Chemistry & Nano Science, Ewha Womans University — Rhenium trioxide (ReO_3) is well known as an unusual transition metal oxide with unexpectedly high electrical conductivity close to that of copper. We present the synthesis of highly crystalline metallic rhenium trioxide (ReO_3) nanowires. ReO_3 nanowires were grown on a 200 nm silica-covered Si (001) wafer by atmospheric-pressure chemical vapor deposition (APCVD) at about 300 ° without any catalyst. The wafer was placed in the quartz boat approximately 15 cm downstream from the fine mashed ReO_3 powder and heated at 320 ° with flowing of high purity Ar (500 sccm) for 2 h and then kept at 450 ° for an additional 3 h. The two-step heating enhanced the growth of ReO_3 nanowires. The structures and morphologies were examined using scanning electron microscopy (FE-SEM) and high-resolution electron microscopy (HRTEM). Based on HRTEM, the ReO_3 nanowires exhibit a core of perfect cubic perovskite type single crystal structure with a shell of thin amorphous and disordered structures of less than 2 nm in the near surface layers. Possibly this is due to proton intercalation induced by the surface reaction of single crystal ReO_3 with water.

S1.00070 The effect of frequency noise on the spectral response of nanomechanical oscillators

FENGPEI SUN, Department of Physics, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong, JIE ZOU, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, HO BUN CHAN, Department of Physics, The Hong Kong University of Science and Technology, Clear Water Bay, Kowloon, Hong Kong — We study the spectral response of an underdamped nanomechanical oscillator in the presence of frequency noise. Motion of a nanobeam is excited and measured using the magnetomotive technique. Telegraph noise is applied on nearby side gates, so that the eigenfrequency of the nanobeam randomly jumps back and forth between two values due to electrostatic coupling. This arrangement is analogous to a mechanical oscillator dispersively coupled to a classical or quantum two-level system. The spectrum displays two distinct peaks when the two eigenfrequencies are separated by a distance larger than the damping constant λ of the oscillator. As the switching rate $\dot{W}$ of the telegraph noise increases, we observe that the two peaks merge into one. The width of the single spectral peak decreases with increasing $\dot{W}$. At $\dot{W} \gg \lambda$, the spectral width approaches its intrinsic value as if frequency noise is absent. The results are in agreement with theoretical predictions.

S1.00071 Self-standing Hybrid Nanofibers of TiO_2 and TiO_2 /Hydroxyapatite: Application in

Photocatalytic and Photovoltaic Systems, PARVANEH ROUHANI, Physic Department, Sharif University of Technology, Tehran, Iran, NIMA TAGHAVINIA TEAM, MASOUD RAHMAN TEAM, LEYLA SHOOSHTARI TEAM — A Hybrid fibers of Hydroxyapatite TiO_2 , HAP/ TiO_2 with modified photocatalytic properties were synthesized using a template method. Liquid phase deposition (LPD) technique was employed to grow TiO_2 layers on cellulose fibers, followed by deposition of HAP from a pseudo body solution, and finally heat removing the cellulose template. The resulting material has a fibrous structure, mimicking the cellulose fibers shape, and have a typical surface area of 114 m^2/g , compared to 74 m^2/g for pure TiO_2 fibers. Adsorption and photocatalytic degradation tests showed that addition of HAP to TiO_2 fibers increased the adsorptive from 17% to 35%. Nano particulated TiO_2 fibers as one-dimensional long structures were introduced into TiO_2 P25 nano particle films using co-electrophoretic deposition. This resulted in less porosity and higher roughness factor of the films that provided more favorable conditions for electron transport. The films used as the photoanode of a dye solar cell (DSC) produced 65% higher photovoltaic efficiency. TiO_2 fibers can be excellent binders in single-step, organic-free electrophoretic deposition of TiO_2 for DSC photoanode.

S1.00072 Family-Dependent Rectification Characteristics in Ultra-Short Graphene Nanoribbon p-n Junctions, JIAXIN ZHENG, XIN YAN, LILI YU, HONG LI, RUI QIN, State Key Laboratory of Mesoscopic Physics, Department of Physics, Peking University, Beijing 100871, P. R. China, GUANGFU LUO, Department of Theoretical and Computational Molecular Science, Institute for Molecular Science, Okazaki 444-8585, Japan, ZHENGXIANG GAO, DAPENG YU, JING LU, State Key Laboratory of Mesoscopic Physics, Department of Physics, Peking University, Beijing 100871, P. R. China — We present the first transport property investigation of a-few-nm-long armchair graphene nanoribbon (AGNR) p-n junctions by using first-principles method. Intriguingly, family-dependent rectification is observed. To be specific, traditional rectification effect in the forward direction is observed in the AGNR p-n junctions with $3n$ and $3n+2$ widths whereas reverse rectification effect is observed in the AGNR p-n junctions with $3n+1$ width. The analysis of the spatial distribution of molecular projected self-consistent Hamiltonian eigenstates and the projected density of states give an insight of the observed results.

S1.00073 Chirality Distribution Measurements of the NIST Single-Wall Carbon Nanotube Reference Material Using Resonance Raman Spectroscopy¹, L.F. SCHEEL², J.R. SIMPSON³, Towson University, J.A. FAGAN, A.R. HIGHT WALKER, National Institute of Standards and Technology (NIST) — The ability to rapidly and easily determine the chiral vector distribution within a nanotube population remains a key measurement need for carbon nanotube processing and applications. We report Resonance Raman Spectroscopy (RRS) measurements of a SWCNT reference material from NIST. The SWCNT samples were synthesized using the CoMoCat method, dispersed in aqueous solutions by wrapping in deoxycholate surfactant, and separated by length using ultracentrifugation. We measure Raman spectra over a wide range of excitation wavelengths from 457 nm to 850 nm using a series of discrete and continuously tunable laser sources coupled to a triple-grating spectrometer with a liquid-nitrogen-cooled detector. The spectra reveal Raman-active vibrational modes including the low-frequency radial breathing mode and higher-order modes. Chirality distributions are determined from the Raman spectra, specifically the RBM frequency and energy excitation profiles, together with input from theoretical models. RRS is sensitive to both major and minor chiral species in the sample. We will compare the resulting chirality distribution obtained from RRS with those obtained from other orthogonal measurement techniques.

¹JRS acknowledges support from the Research Corporation's CCSA.

²Presently at Oak Ridge National Laboratory.

S1.00074 A study of 3-dimensionally periodic carbon nanostructures, MING YIN, Benedict College Columbia, SC 29204, MICHAEL BLEIWEISS, JAFAR AMIRZADEH, TIMIR DATTA, University of South Carolina Columbia, SC 29208, FOUZI ARAMMASH, Benedict College, Columbia, SC 29204 — Electronic structures with intricate periodic 3-dimensional arrangements at the submicron scale were investigated. These may be fabricated using artificial porous opal substrates as the templates in which the targeted conducting medium is introduced. In the past these materials were reported to show interesting electronic behaviors. [Michael Bleiweiss, et al "Localization and Related Phenomena in Multiply Connected Nanostructured," BAPS, Z30.011, Nanostructured Materials Session, March 2001, Seattle]. Several materials were studied in particular disordered carbon which has been reported to show quantum transport including fractional hall steps. The results of these measurements, including the observation of localization phenomena, will be discussed. Comparisons will be made with literature data.

S1.00075 Charge redistribution and interlayer coupling in twisted bilayer graphene under electric fields, PATRICIO VARGAS, ERIC SUAREZ MORELL, Physics Department, Universidad Tecnica Federico Santa Maria, Casilla 110-V, Valparaiso, Chile, LEONOR CHICO, LUIS BREY, Departamento de Teoria y Simulacion de Materiales, Instituto de Ciencia de Materiales de Madrid, CSIC, E-28049 Cantoblanco, Spain — There is an ongoing controversy on the electronic characteristics of rotated bilayer graphene. Several experiments on rotated few-layer graphene grown on SiC show an electronic behavior similar to that of single-layer graphene, with the same carriers' velocity as that of an isolated graphene monolayer; for this reason, these systems have been considered as composed of uncoupled graphene sheets. We investigate the electronic density redistribution of rotated bilayer graphene under a perpendicular electric field, showing that the layers are actually coupled even for large angles. This layer-layer coupling is evidenced by the charge transfer on these structures as a function of the external voltage. We find an inhomogeneous excess charge distribution that is related to the moiré patterns for small angles, but that persists for larger angles where the carriers' velocity is equal to that of single layer graphene. Our results show that rotated bilayer systems are coupled for all rotation angles.

S1.00076 Spin-density-wave instability in graphene doped near the van Hove singularity, RALPH VAN GELDEREN, DMYTRO MAKOGON, Utrecht University, RAFAEL ROLDÁN, Instituto de Ciencia de Materiales de Madrid, CRISTIANE MORAIS SMITH, Utrecht University — We study the instability of the metallic state towards the formation of a new ground state in graphene doped near the van Hove singularity. The system is described by the Hubbard model and a field theoretical approach is used to calculate the charge and spin susceptibility. We find that for repulsive interactions, within the random phase approximation, there is a competition between ferromagnetism and spin-density wave (SDW). It turns out that a SDW with a triangular geometry is more favorable when the Hubbard parameter is above the critical value $U_c(T)$, which depends on the temperature T , even if there are small variations in the doping. Our results can be verified by ARPES or neutron scattering experiments in highly doped graphene.

S1.00077 Effects of static charging and exfoliation of layered crystals, MEHMET TOPSAKAL, SALIM CIRACI, UNAM-Institute of Materials Science and Nanotechnology — Using first-principle plane wave method we investigate the effects of static charging on structural, electronic and magnetic properties of suspended, single layer graphene, graphane, fluorographene, BN and MoS(2) in honeycomb structure. The limitations of periodic boundary conditions in the treatment of charged layers are clarified. Upon positive charging the band gaps between the conduction and valence bands increase, but the single layer nanostructures become metallic owing to the Fermi level dipping below the maximum of valence band. Moreover, their bond lengths increase leading to phonon softening. As a result, the frequencies of Raman active modes are lowered. High level of positive charging leads to structural instabilities in single layer nanostructures, since their specific phonon modes attain imaginary frequencies. Similarly, excess positive charge is accumulated at the outermost layers of metallized BN and MoS(2) sheets comprising a few layers. Once the charging exceeds a threshold value the outermost layers are exfoliated. Charge relocation and repulsive force generation are in compliance with classical theories.

S1.00078 Effects of Peptide Adsorption on the Electronic Properties of Graphene, BRAHIM AKDIM, ZHIFENG KUANG, SANG KIM, RAJESH NAIK, BARRY FARMER, AFRL, TIFFANY WALSH, University of Warwick, RUTH PACTHER, AFRL — In this work we aim to explain the increase in the electrical conductance in a single-layer graphene (SLG) field-effect transistor (FET) upon binding the peptide HSSYWYAFNNKT, which we previously demonstrated. The adsorption of the peptide onto the SLG has been carefully modeled by applying empirical molecular dynamics simulations with the AMOEBA force-field. The peptide adsorbed SLG structure demonstrates $\pi - \pi$ stacking with aromatic amino acids, namely His, Tyr, Thr and Ph. Based on this large-scale peptide-SLG system, calculations on the electron transport using the nonequilibrium Green's function formalism at the extended Huckel level were carried out. Transmission eigenchannels and spectra, projected density of states, effects of modeling realistic leads (gold vs. graphene) and $I - V$ characteristics will be discussed in detail. In this context, suppositions as to the mechanism of increased conductance for the peptide-SLG FET will be proposed.

S1.00079 Heat transfer at interfaces with graphene, ZHIPING XU, Tsinghua University — Graphene has an ultrahigh in-plane thermal conductivity (5500 W/mK), but simultaneously a much lower conductivity along the c-axis in graphite or at the interfaces with other materials. As graphene finds more and more applications in nanoelectronics and high-performance composites, these interfaces become critically important in defining their heat dissipation and conduction performance. Unlike conventional interfaces in materials such as grain boundaries, the interfaces with graphene can be tuned by chemically modifying the graphene monolayer or intercalating the interfaces. These nano-engineering proposals require fundamental understanding of the heat transfer mechanisms. In order to obtain some insights on the transfer processes of mechanical and thermal energy across these interfaces, we perform series of molecular dynamics simulations, in combination with theoretical analysis by considering the quasi-ballistic nature of phonon transport at nanoscale. The result shows that heat dissipation or transport can be divided into two stages, beginning with an interface-controlled process. The effects of interface structures and binding properties on the whole process will be covered in this talk, with several examples showing how the interfacial thermal transfer can be engineered.

S1.00080 Nonlocal resistance in a bilayer graphene under a magnetic field¹, CHANG-RAN WANG, TSUNG-YEH YANG, CHIA-TSO HSIEH, YUNG-YU CHIEN, WEI-LI LEE, Institute of Physics, Academia Sinica — We have performed nonlocal resistance measurement in bilayer graphene with Hall-bar geometry under high magnetic fields. We observed large nonlocal resistance near the charge neutral point (CNP) which grows rapidly with field intensity. At 15 Tesla, the relative increase of nonlocal resistance near CNP is an order of magnitude larger than the local resistance at the same condition. This behavior is similar to the recent nonlocal measurement result in a single layer graphene. The detailed field and temperature dependences will be presented.

¹National Science Council in Taiwan

S1.00081 Edge currents and an array of nanopores in zigzag and chiral graphene nanoribbons as a route toward high-ZT thermoelectrics, PO-HAO CHANG, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716-2570, USA — We exploit peculiar transport properties of graphene nanoribbons (GNRs) with zigzag or chiral edges where local current density of quasiparticles close to the Dirac point is largely confined around their edges. Thus, drilling an array of nanopores in the interior of such nanoribbons will not affect much the electronic transport while substantially suppressing the phonon transport in sufficiently long wires. For nanoribbons of length $\sim 1 \mu\text{m}$ and width 4.1 nm and nanopores of diameter 2 nm, the ZT for both zigzag GNRs and chiral GNRs is $\simeq 4$ at $T = 77 \text{ K}$ and $\simeq 1.5$ at $T = 300 \text{ K}$. With slightly asymmetric arrangement of nanopores, the ZT of zigzag GNRs can be further enhanced to reach $\simeq 13$ at $T=77 \text{ K}$ and $\simeq 5$ at $T=300 \text{ K}$.

S1.00082 Low-frequency noise in graphene FETs, NAN SUN, GERALD ARNOLD, KRISTOF TAHY, JIANCHUN ZENG, DEBDEEP JENA, HUILI XING, STEVEN RUGGIERO, University of Notre Dame, UNIVERSITY OF NOTRE DAME TEAM — We report on the low-frequency electronic noise in graphene-based FET structures. Samples were created using standard e-beam lithography and exfoliated, epitaxially-grown, and CVD-grown single-layer graphene films. The lowest overall noise was observed in epitaxially-grown films on SiC. We also investigated the gate dependence of the noise amplitude. Previous studies have suggested that the noise dependence should be either Λ -shaped in keeping with the Hooge model, or M-shaped as described by the charge-noise model. We here propose a new noise model based upon resonant scattering theory, which not only explains both types of gate dependence on noise, but also models the general noise behavior in graphene.

S1.00083 Magnetic Properties of Graphene Superlattices, SI WU, University of Waterloo, MATTHEW KILLI, ARUN PARAMAKANTI, University of Toronto — We studied graphene superlattices (SL) in the presence of magnetic fields. We found magnetic properties of single layer and bilayer graphene SLs in a weak magnetic field are strongly determined by emergent Dirac physics. Moreover, the spatial anisotropy of diagonal conductivities can be reversed when magnetic field is tuned from weak to intermediate strength. In a strong magnetic field, all anisotropies disappear and results from pristine graphene are restored.

S1.00084 ABSTRACT WITHDRAWN —

S1.00085 Co-adsorption of n Monomer Species on Terraces and Nanotubes¹, ALAIN PHARES, Villanova University — We consider the partition function, Z , of the system of n monomer species adsorbed on a terrace or a nanotube of arbitrary periodic lattice geometry, L atomic sites in length, and M' sites in the width of the terrace or in the normal cross-section of the nanotube. Z is related to the eigenvalues of a real and non-negative matrix (**T** matrix) of rank $(n+1)^M$, where M is an integer multiple of M' . In the infinite- L limit, we also prove that Z is the largest eigenvalue of the **T**-matrix, raised to the power $1/M$. Because the rank of this matrix increases exponentially with M , we develop a technique for its recursive construction applicable to any lattice geometry, which is easily programmed and efficiently adaptable for supercomputing and multiparallel processing. As examples, we consider the co-adsorption on square, equilateral triangular, and honeycomb surfaces. This general formulation can now be applied to model a whole new set of experiments involving the coadsorption of two or more monomer species, on terrace or nanotube surfaces with various periodic lattice structures.

S1.00086 SEMICONDUCTORS —

S1.00087 Temperature dependence of optoelectronic properties of $\text{CdS}_x\text{Se}_{1-x}$, $\text{CdS}_x\text{Te}_{1-x}$, $\text{CdSe}_x\text{Te}_{1-x}$, DONGGUO CHEN, NUGGEHALI RAVINDRA, New Jersey Institute of Technology — Temperature dependence of the optoelectronic properties of ternary compounds, $\text{CdS}_x\text{Se}_{1-x}$, $\text{CdS}_x\text{Te}_{1-x}$ and $\text{CdSe}_x\text{Te}_{1-x}$, are presented. The analysis of the temperature dependence of the energy gap of these compounds, for various compositions, is discussed in light of the Varshni formula. Extension of this study is then made to include the contributions of the temperature dependence of the gap of the component binary semiconductors. The model takes into account the implications of the above results on the refractive indices of these ternary compound semiconductors.

S1.00088 Modeling Random Dopant Fluctuation Effects in Nanoscale Tri-Gate MOSFETs, JOSHUA OGDEN, ABDUSSAMAD MUNTAHI, KRISHNA YALAVARTHI, SHAIKH AHMED, Southern Illinois University — The tri-gate FET has been hailed as the biggest breakthrough in transistor technology in the last 20 years. The increase in device performance (faster switching, low power, improved short channel effects, etc.), coupled with the reduction in device size, would allow for huge gains in the electronics industry. In this work, an atomistic quantum-corrected Monte Carlo 3-D device simulator was used to not only investigate the validity of these claims, but also how quantum size quantization and random dopant fluctuation (RDF) affect the tri-gate FET performance and how to curb these issues. The main findings are as follow: 1) carrier scattering leads to ON current degradation of $\sim 30\%$ and hence cannot be ignored; 2) deviations in threshold voltage due to random channel doping are smaller in the tri-gate FET; 3) RDF due to the source/drain discreteness can be engineered by adjusting the source/drain junction depth. With randomness reduced, the overall performance should increase when used in ICs, where consistency in device characteristics is essential.

S1.00089 ABSTRACT WITHDRAWN —

S1.00090 Spin Torque and Its Efficiency in 3D Rashba Models with Localized Spins, KAZUHIRO TSUTSUI, SHUICHI MURAKAMI, Tokyo Institute of Technology — In addition to the magnetization reversal by the spin-transfer torque, the magnetization reversal driven by a strong spin-orbit coupling has been intensely investigated experimentally and theoretically. In this presentation, we focus on 3D Rashba models coupled with localized spins, and study the spin torque theoretically. This is motivated by the recent discovery of BiTeI as 3D Rashba systems. As a result, we find that the spin torque in 3D Rashba models is largely enhanced in the high-carrier-density regime compared with 2D Rashba models. We also find that the spin-torque efficiency defined as the ratio between the spin torque and the electric current is enhanced when the Fermi energy lies on only lower band, both in 3D and 2D. As we change the Rashba spin-orbit coupling, the spin-torque efficiency becomes maximum when the Rashba spin-orbit coupling is comparable to the exchange coupling to the localized spins. The optimum spin-torque efficiency becomes large when the Rashba spin-orbit coupling is large, and it is preferable for the magnetization reversal with smaller amount of current injection.

S1.00091 All-optical patterning of Nuclear Polarization in Gallium Arsenide¹, YUNPU LI, JONATHAN P. KING, JEFFREY A. REIMER, CARLOS A. MERILES, None — We employ Stray-Field NMR Imaging for ⁶⁹Ga and ⁷¹Ga to monitor the spatially-dependent polarization of nuclear spins in semi-insulating bulk GaAs at 9.4 T. By exploiting two competing mechanism as hyperfine and quadrupolar interaction for optical nuclear polarization at different illumination intensities and wavelengths, we demonstrate all-optical creation of three-dimensional patterns of positive and negative nuclear polarization. We also observe the isotope dependence of the patterning process, where different isotopes (⁶⁹Ga and ⁷¹Ga) have opposite polarization at the same location in the sample. By combining the optical pumping with varied NMR pulse sequences, we demonstrate the control of nuclear polarization.

¹The authors acknowledge support from NSF under Project ECS0608763.

S1.00092 Dynamical simulation of a two-electron spin qubit based on hyperfine interaction¹, MIGUEL ANGEL RODRIGUEZ-MORENO, Centro de Investigaciones en Semiconductores ICUAP, LILIA MEZA-MONTES, Instituto de Física BUAP, DAVID HERNANDEZ DE LA LUZ, Centro de Investigaciones en Semiconductores ICUAP — The interaction with the nuclear field is one of the main sources of decoherence in solid state quantum bits. However, recently it has been shown that hyperfine interaction can also be used to manipulate the spin state of electrons in double quantum dots. In this work, we simulate numerically the dynamics of a spin-based quantum bit consisting of two electrons confined in a double quantum dot, including the interaction with a random nuclear field. The two electron wavefunction is built using an antisymmetric function expansion and the total hamiltonian is discretized spatially using finite differences. For the dynamic simulation, an exponential approximation of the time propagator is used. In order to model the hyperfine interaction, a normally-distributed random magnetic field is assigned to each simulation grid point. The dynamics of the system is calculated by averaging over an ensemble of quantum dots. It is shown how the hyperfine field can be used to drive transitions between singlet and triplet states, an effect that has already been found experimentally. Particularly, it is shown how these transitions can be controlled using an applied electric field, thus allowing for the realization of a two-electron quantum gate.

S1.00093 ABSTRACT WITHDRAWN —

S1.00094 The interaction of hydrogen donors with compensating acceptors in semiconducting oxides, JOEL VARLEY¹, HARTWIN PEELAERS, ANDERSON JANOTTI, CHRIS VAN DE WALLE, University of California, Santa Barbara — Hydrogen is a common impurity that can act as a donor and an acceptor in a semiconductor, leading to a variety of behavior that may impact the desired performance. In one class of materials, wide-band-gap semiconducting oxides, the role of H has been strongly linked to n-type conductivity. In these systems H acts predominantly or exclusively as a shallow donor as an interstitial or while substituting on an O site. In addition to the resulting n-type conductivity, the incorporation of H or other donor dopants also leads to an increase in compensating acceptor defects. The interaction of H with cation vacancies, the dominant acceptor impurity involved in compensation, has yet to be fully explored. Using first-principles calculations employing hybrid functionals, we investigate the complexes formed between cation vacancies and interstitial H donors. We report on the formation energies, binding energies, and vibrational frequencies of the hydrogenated cation vacancies in the transparent semiconducting oxides SnO₂, In₂O₃ and Ga₂O₃ [1]. We find that H can interact strongly with vacancies in both atomic and molecular form, and can have a significant impact on the electrical properties of devices employing these oxides.

S1.00095 Electronic properties of doped cesium niobate, LU WANG, RENAT SABIRIANOV, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68132, ROBERT SMITH, Department of Chemistry, University of Nebraska at Omaha, Omaha, NE 68132, CHIN LI CHEUNG, Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE 68588 — Antiferroelectric cesium niobate Cs₂Nb₄O₁₁ (CNO) is known to have novel water splitting capability. It was reported that the broad blue photoluminescence was observed at 77 K. Particularly when treated with NiO₂, the water-splitting activity under UV-light irradiation increased five times. In this work we present systematic studies of the electronic properties of doped CNO by using density functional theory calculations. We first obtain direct band gap of 3.12 eV for the pure sample that agrees well with experimental value of 3.55 ± 0.05 eV. Then we notice, at both the high and low-density regions, the band gap effectively reduced after oxygen atoms substituted by sulfur and nitrogen, and niobium by vanadium. As a final point, we present and discuss relations between impurity concentration and band gap reduction.

S1.00096 Inspecting the microstructure of electrically active defects at the Ge/GeO_x interface, MARCO FANCIULLI, Department of Material Science, University of Milano Bicocca, Italy and MDM Laboratory, IMM-CNR, Agrate Brianza, Italy, SILVIA BALDOVINO, ALESSANDRO MOLLE, MDM Laboratory, IMM-CNR, Agrate Brianza, Italy — High mobility substrates are important key elements in the development of advanced devices targeting a vast range of functionalities. Among them, Ge showed promising properties promoting it as valid candidate to replace Si in CMOS technology. However, the electrical quality of the Ge/oxide interface is still a problematic issue, in particular for the observed inversion of the n-type Ge surface, attributed to the presence of dangling bonds inducing a severe band bending [1]. In this scenario, the identification of electrically active defects present at the Ge/oxide interface and the capability to passivate or anneal them becomes a mandatory issue aiming at an electrically optimized interface. We report on the application of highly sensitive electrically detected magnetic resonance (EDMR) techniques in the investigation of defects at the interface between Ge and GeO₂ (or GeO_x), including Ge dangling bonds and defects in the oxide [2]. In particular we will investigate how different surface orientations, e.g. the (001) against the (111) Ge surface, impacts the microstructure of the interface defects. [1] P. Tsipas and A. Dimoulas, Appl. Phys. Lett. 94, 012114 (2009) [2] S. Baldovino, A. Molle, and M. Fanciulli, Appl. Phys. Lett. 96, 222110 (2010)

S1.00097 Quantum Transport in Ultra-scaled Junctionless Transistors¹, SUNGGEUN KIM, Purdue University, MATHIEU LUISIER, ETH Zurich, GERHARD KLIMECK, Purdue University, NCN COLLABORATION² — As the dimensions of metal-oxide-semiconductor field-effect transistors have been scaled down to a few nano-meters, short channel effects have started to significantly degrade their performance. The junctionless transistor is an alternative device structure which is expected to reduce short channel effects. However, an extreme device scaling raises another issue, namely, source-to-drain tunneling. Junctionless transistors contain several doping atoms in the channel which can enhance tunneling processes and cause electrons to scatter with them. Through self-consistent quantum transport simulations based on the tight-binding model with electron-phonon scattering included, it is found that junctionless nanowire transistors with a gate length of 5 nm do not outperform conventional inversion-mode transistors with the same dimension in terms of their on-state characteristics, mainly due to impurity scattering in the channel. The advantage of the junctionless transistor in the subthreshold region vanishes due to large tunneling currents through doping impurities.

S1.00098 Band crossing in isovalent semiconductor alloys with large size mismatch, HUI-XIONG DENG, SU-HUAI WEI, National Renewable Energy Laboratory — Mixing isovalent compounds AC with BC to form alloys $A_{1-x}B_xC$ has been an effective way in band structure engineering to enhance the availability of material properties. In most cases, the mixed isovalent atoms A and B, such as Al and Ga in $Al_{1-x}Ga_xAs$ or As and Sb in $GaAs_{1-x}Sb_x$ are similar in their atomic sizes and chemical potentials; therefore, the physical properties of $A_{1-x}B_xC$ change smoothly from AC to BC. However, in some cases when the chemical and size differences between the isovalent atoms A and B are large, adding a small amount of B to AC or vice versa can lead to a discontinuous change in the electronic band structure. These large size- and chemicalmismatched (LSCM) systems often show unusual and abrupt changes in the alloys' material properties, which provide great potential in material design for novel device applications. In this report, based on first-principles band-structure calculations we show that for LSCM $GaAs_{1-x}N_x$ and $GaAs_{1-x}Bi_x$ alloys at the impurity limit the N (Bi)-induced impurity level is above (below) the conduction-(valence-) band edge of GaAs. These trends reverse at high concentration, i.e., the conduction-band edge of $GaAs_{1-x}N_x$ becomes an N-derived state and the valence-band edge of $GaAs_{1-x}Bi_x$ becomes a Bi-derived state, as expected from their band characters. We show that this band crossing phenomenon cannot be described by the popular BAC model but can be naturally explained by a simple band broadening picture.

S1.00099 Engineering Efficiency Droop in InGaN/GaN Multiple Quantum Well LEDs, YASH-VANTH PUTTASWAMY, SASI SUNDARESAN, KRISHNA YALAVARTHI, SHAIKH AHMED, Southern Illinois University — In this work, we address the technologically important issue of efficiency droop pronounced in InGaN/GaN multiple quantum well (QW) LEDs. A two-fold modeling approach is employed where: 1) the NEMO 3-D tool is used to compute the atomistic strain fields and associated polarization potentials in the active region, and 2) the outputs from NEMO 3-D are then coupled to the Synopsys TCAD tool to determine the terminal electrical and optical properties of the device. Next, a series of numerical experiments are performed that mainly aims to improve the efficiency droop without compromising the internal quantum efficiency (IQE) of the device. These include: 1) varying the QW thickness, 2) employing different configurations of tri-material barriers, 3) varying the molar concentration of the barrier materials, and 4) varying the doping density in the barrier region.

S1.00100 Using Polarization Effects in Deep UV Nitride Emitters, G. BRUMMER, H. SUN, A. NIKIFOROV, T. MOUSTAKAS, Boston University — We numerically and experimentally investigate the effects of compositional grading in high Al content AlGaN, with applications to deep UV emitters. The large polarization fields create a fixed charge density in the graded regions, which by necessity, are screened by mobile electrons and holes. The net effect is a pn junction band structure in which bound polarization charge assumes the role of immobile ionized dopants, and the screening charge assumes the role of mobile carriers released from the dopants. Using this phenomenon it should be possible to overcome the difficulties in doping high Al content AlGaN, and make efficient deep UV light emitting diodes, and lasers.

S1.00101 Improvement of M-plane GaN thin film grown on pre-annealing β -LiGaO₂ (100) substrate¹, CHIA-HSUAN HU, CHENG-HUNG SHIH, IKAI LO, YING-CHIEH WANG, CHEN-CHI YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan, MITCH CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung, Taiwan — M-plane GaN thin films have been grown on β -LiGaO₂ (100) substrates by plasma-assisted molecular-beam epitaxy. In order to improve the quality, we tried to grow M-plane GaN thin films on pre-annealed in vacuum and in air ambient LiGaO₂ (100) substrates. X-ray diffraction data indicated that the M-plane GaN thin film grown on the LiGaO₂ (100) substrate pre-annealed in air ambient has better crystal quality than that grown on the LiGaO₂ (100) substrate pre-annealed in vacuum. In addition, we found that the strain between GaN and LiGaO₂ substrate can be relaxed by growing GaN thin film on pre-annealed LiGaO₂ substrate in air. It reveals that LiGaO₂ substrate annealing in air ambient can suppress the formation of lithium-rich surface effectively to grow a high quality M-plane GaN thin film on the LiGaO₂ substrate.

¹The project was supported by the National Research Council of Taiwan(NRC 98-2112-M-110-003-MY3)

S1.00102 The Growth of InGaN on Single Crystal ZnO (000-1) Substrate by Metal Modulation Epitaxy Method¹, YING-CHIEH WANG, C.H. SHIH, IKAI LO, C.C. YANG, C.D. TSAI, Department of Physics, National Sun Yat-Sen University, Kaohsiung, Taiwan — The growth of InGaN film on single crystal ZnO (000-1) substrate by plasma assisted-molecular beam epitaxy has been investigated. The metal modulation epitaxy (MME) technique was applied in this experiment. The growth mechanism of InGaN thin film on ZnO (000-1) was in the form of 2D growth model by *in-situ* observation of reflection high-energy electron diffraction (RHEED). From the observation of atomic force microscope (AFM), we found that surface roughness of InGaN thin film can be improved using MME technique. The crystal quality and the indium content of InGaN thin film was determined by the X-ray diffraction method. The full width at half-maximum (FWHM) and the indium content of InGaN thin film is 298.64 arc-sec and 17 %, respectively. According to the calculation of bowing parameters, the 17 % indium content of InGaN thin film closed to $In_{0.18}Ga_{0.82}N$ which is perfect lattice-matching to ZnO (000-1). The micro-structure analysis of InGaN grown on ZnO by high-resolution transmission electron microscope (HR-TEM) was performed, which shows that the interface between the substrate and the film is clearly indicating $In_{0.17}Ga_{0.83}N$ to be lattice-matching with ZnO (000-1).

¹The project is supported by National Reaserch Council of Taiwan (NRC 98-2112-M-110-003-MY3).

S1.00103 Studies on the Growth and Characterization of hexagonal boron nitride thin films, M.L. NAKARMI, B. CAI, Department of Physics, Brooklyn College and Graduate Center of the CUNY, Brooklyn, NY 11210, A. DELMONT, A. SPROW, R.C. RAI, Department of Physics, SUNY College at Buffalo, Buffalo, NY 14222 — Hexagonal Boron Nitride (h-BN) with a direct band gap of ~ 5.9 eV has emerged as a promising deep ultraviolet photonic material. We will present the studies on the growth and characterization of h-BN thin films grown on different substrates such as sapphire, YSZ, quartz, and metal substrates. The samples were grown by electron beam evaporation technique. Atomic force microscopy, x-ray diffraction, optical spectroscopy, and Hall effect measurement were employed to characterize surface morphology, structural, optical and electronic, and electrical properties, respectively. We will also present the results of Mg-doped h-BN thin films in an effort to make p-type BN. Implementation of our findings on the development of deep ultraviolet photonic devices will also be discussed.

S1.00104 Electrical characterization of homoepitaxially deposited boron-doped diamond¹, SUNIL KARNA, YOGESH VOHRA, GOPI SAMUDRALA, GEORGI TSOI, None — Homoepitaxial boron doped single crystal diamond films were deposited on 100 oriented lb type synthetic diamond substrates via microwave plasma chemical vapor deposition. The gas phase chemistry of 6% methane/ hydrogen ratio and 5000 ppm of (B/C)_{gas} was used for all samples deposited at different temperature from 900 to 1200°C. The deposited films were characterized by FTIR, AFM, Raman spectroscopy and XRD Rocking curve measurement to assess doping level, surface morphology and crystalline quality. The high growth rate 16 micron per hour has been obtained by optimizing growth parameters such as microwave power, chamber pressure, and gas flow rate. The four-probe electrical resistance measurements on boron-doped samples were conducted between 14 K and 350 K and show competing effects of intrinsic and hoping conductivity.

S1.00105 ABSTRACT WITHDRAWN —

S1.00106 A simple approach to the polytypism in boron nitride, TOMONORI ITO, TORU AKIYAMA, KOHJI NAKAMURA, Department of Physics Engineering, Mie University — Boron nitride (BN) is well known as having a polytype including cubic (c-BN) with zinc blende structure (3C) and hexagonal BN (h-BN) phases similarly to C. From the experimental viewpoints, it is found that h-BN appears at ambient temperature and pressure whereas c-BN is preferable at high temperature and high pressure. In order to clarify its polytypism, there have been some ab initio calculations mainly focusing on four-fold coordinated structures such as 3C-, 6H-, 4H-, and 2H-BN. Although the ab initio calculations predict the polytypes for bulk BN, the physical interpretation of the polytypism is still unclear because of the complexity of identifying individual contribution in the ab initio calculations. In order to make up this deficiency, we investigate the polytypism for BN in bulk form using a simple approach on the basis of empirical interatomic potentials. The calculated respective energy differences between 6H and 3C, between 4H and 3C, and between 2H and 3C are 5.0 meV, 7.5 meV, and 17.1 meV when the ionicity $\epsilon_i=0.143$ for BN is employed. These results are consistent with previously reported ab initio calculations. Furthermore, we also discuss the relative stability between h-BN and c-BN using this simple approach.

S1.00107 Morphological Studies on GaN Nanowire Growth Modes¹, ZHENG MA, XIAOHONG AN, SWASTIK KAR, MONEESH UPMANYU, EUGEN PANAITESCU, LATIKA MENON, Northeastern University — We describe our results on growth of single crystal GaN nanowires in three different growth modes (straight, serrated and epitaxial) on catalyst-patterned substrates by means of chemical vapor deposition. The growth is carried out in a tube furnace wherein gallium oxide is used as reactor source and a mixture of ammonia and hydrogen gas is used as precursor. Growth of GaN nanowires are demonstrated on both Au and Ni-catalyst patterned substrates. We show that by controlling the deposition parameters, specifically the size of the catalyst and amount of gallium oxide, we can control the growth morphology. While straight GaN nanowires typically grow on substrates patterned with catalyst particles with dimensions of the order of 100nm, the epitaxial nanowires grow on substrates with much smaller dimensions of catalyst particles 50nm. The newly demonstrated GaN wire growth mode with periodic serrations, typically grow under conditions involving large catalyst size ~ 300 nm and excess gallium oxide. In this work, a detailed investigation is carried out on the structural properties of the three different growth modes by means of high resolution transmission microscopy, x-ray diffraction and Raman spectroscopy studies in order to obtain a better understanding of their growth mechanism.

¹NSF ECCS Grant # 0925285 is acknowledged.

S1.00108 Pulse-duration dependent structural change mechanism in Ge₂Sb₂Te₅, DONG HAK KIM, DAEYOUNG LIM, Kyung Hee University — The mechanism of ultrafast structural change in Ge₂Sb₂Te₅ (GST) induced by optical excitation was studied by using pump-probe coherent optical phonon (COP) spectroscopy. The structural change mechanism showed strong dependency on the duration of the pump pulse. While the frequency of displacively generated A₁ COP was observed to red-shift (by more than $\sim 5\%$) in the 2-3 ps time-scale for a long pulse excitation (~ 100 fs), it was instantaneous in the case of short pulse excitation. Furthermore, the shifted COP frequency in the intermediate, transient state was almost independent of the pulse duration or the fluence of the optical pump, which, along with the pulse duration dependency, cannot be explained by photoexcited high-density carriers or thermal effect. The strong dependency of the observed time-scale on the pulse duration and the fluence-independent COP frequency in the transient state indicate that coherent atomic motion due to ultrafast COP generation plays a dominant role in the transition to intermediate, transient state.

S1.00109 The Calculation for the Microscopic Capacitance of Gate Electrode in High Electron Mobility Transistors, CHIN-SHENG WU, Yuan Ze University — Novel nanodevices have developed below 60 nm. Accurate characterization requires detailed electronic structure. In field effect transistor, a dielectric layer isolates the channel from the gate electrode. The model is based on the nanoscale MOSFET with gate length 60 nm, channel length 25 nm and insulator thickness 10 nm. The capacitance of the gate is the series combination of the geometric capacitance. Its dielectric constant is associated with the local electron density. The carrier density decreases from the source to drain in the channel. The capacitance is assumed in parallel connection along this direction.

S1.00113 Characterizing Heat Spreading and Performance Degradation in Organic Light-Emitting Diodes, AMELIA PLUNK, Mount Holyoke College, ANDREW DAVIS, University of Massachusetts Amherst, KADHAIR AL-HEMYARI, ALEXI ARANGO, Mount Holyoke College, KENNETH CARTER, University of Massachusetts Amherst, JANICE HUDGINGS, Mount Holyoke College — In this work, we present for the first time high resolution thermal images of operating organic light-emitting diodes (OLEDs) and show that the surface temperature of these devices can be used to map current density and identify the origin of localized defects and performance degradation. Both luminance and lifetime of OLEDs decrease dramatically with increased operating temperature due to self-heating. Furthermore, localized Joule heating at defects results in local hot spots, thus degrading the brightness homogeneity, altering the electro-optical characteristics of the OLED, and leading to electrode delamination and black spots. Increasing the lifetime of OLEDs clearly relies at least in part on improved thermal management. Using thermoreflectance microscopy, we observed evidence of the correlation between structural defects and areas of low current density by examining areas of operating devices which showed visual damage and had a low relative surface temperature. We also show the validity of using thermoreflectance microscopy to perform basic characterization of operating OLEDs, such as examining diode behavior, extrapolating material qualities such as diffusivity and conductivity, and quantifying the heat flow through working devices.

S1.00114 Spatially Resolved Thermal Analysis of High Power LEDs Using Thermoreflectance Microscopy, HEXUAN WANG, KADHAIR AL-HEMYARI, SUSU YAN, JOSEPH SUMMERS, JANICE HUDGINGS, Mount Holyoke College — The efficiency, reliability, and lifetime of high power light emitting diodes (LEDs) depend critically on their operating temperature. The lateral temperature distribution is of particular importance with large area, high power LEDs as defects related to overheating in high power LEDs usually occur at a high rate at the surface. In this work, we present the use of lock-in thermoreflectance imaging to measure the spatially resolved surface thermal distribution of operating LEDs. This non-invasive thermography technique offers high spatial and thermal resolutions. We show that results of thermoreflectance surface temperature are quantitatively consistent with temperature measurements obtained using forward voltage bias and wavelength shift techniques. We demonstrate the power of spatially resolved thermoreflectance by imaging the highly non-uniform surface temperature distribution of an operating LED at high electrical bias power. We conclude that the non-uniform surface temperature distribution is resulted from non-uniformly distributed inject current and overheating at the contacts. We also investigate the thermal impact of encapsulating commercial LEDs with a plastic lens and silicone epoxy.

S1.00115 Optical Properties of PbTe and PbSe¹, CHINEDU EKUMA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA, DAVID SINGH, Material Science and Technology Division, Oak Ridge National Laboratory, TN, USA, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA — We report optical properties of PbTe and PbSe as obtained from first principles calculations with the Tran-Blaha modified Becke-Johnson potential. The results are discussed in relation to existing experimental data, particularly in relation to the temperature dependence of the band gap.

¹Work at ORNL was supported by the Department of Energy, Basic Energy Sciences through the S3TEC Energy Frontier Research Center. Work at LSU was funded in part by the National Science Foundation Award Number: EPS 1003897.

S1.00116 Strained layer relaxation effect on current crowding and efficiency improvement of GaN based LED, DEEDER AURONGZEB, Arizona State University, Department of Electrical Engineering, Tempe, Arizona 85287 — Efficiency droop effect of GaN based LED at high power and high temperature is addressed by several groups based on carrier delocalization and photon recycling effect (radiative recombination). We extend the previous droop models to optical loss parameters. We correlate strained layer relaxation at high temperature and high current density to carrier delocalization. We propose a third order model and show that Shockley-Hall-Read and Auger recombination effect is not enough to account for the efficiency loss. Several strained layer modification scheme is proposed based on the model.

S1.00117 Wigner-crystallization of Rydberg-Polaritons in the lowest Landau level, FABIAN GRUSDIT, MICHAEL FLEISCHHAUER, Department of Physics and Research Center OPTIMAS, TU Kaiserslautern — For electrons and dipolar fermions in the lowest Landau level the critical filling for Wigner-crystallization was shown to be $\nu_c \approx 1/7$ [Baranov et. al., Phys. Rev. Lett. 100 (2008)]. We investigate the fractional quantum Hall effect for Van-der-Waals interacting bosons as realized e.g. by stationary-light polaritons in a Rydberg gas and find no transition to the Wigner crystal (WC). Our numerical studies suggest a crystalline groundstate below $\nu = 1/6$ which is expected to be described by a correlated WC of composite quasiparticles. Taking into account a cut-off in the Van-der-Waals interaction we find the WC to be favorable for large cut-offs. Numerical results for different geometries are presented and realistic implementations are discussed.

S1.00118 INSTRUMENTATION AND MEASUREMENTS —

S1.00119 Kelvin Probe Microscopy and Electrostatic Force Microscopy of reduced graphene oxide platelets, JOSEPH RAHAMIM, CHRISTOPHER KEHAYIAS, Physics and Astronomy, Tufts University, SAMUEL MACNAUGHTON, SAMEER SONKUSALE, Electrical and Computer Engineering, Tufts University, CRISTIAN STAIL, Physics and Astronomy, Tufts University — We present combined Scanning Kelvin Probe Microscopy (SKPM) and Electrostatic Force Microscopy (EFM) measurements on reduced graphene oxide (rGO). Although the as-synthesized graphene oxide is insulating, controlled reduction chemistry can render this material semiconducting or even semi-metallic. The availability of several types of oxygen functional groups allows rGO to interact with a wide range of organic and inorganic compounds. We perform sensitive SKPM and EFM measurements on patterned rGO electronic circuits and show that the electrical potential and charge distribution are significantly changed when the device is exposed to various organic dopants. We also demonstrate that these experiments allow a systematic study of the conducting channels through rGO as a function of the chemical dopant.

S1.00120 Length, Radius, and Tilt Angle Control of Carbon Nanotube Probes for High Resolution Atomic Force Microscopy, BENJAMIN ALEMAN, BIBIANA ONOA, University of California, Berkeley, CLAUDIO RIVETTI, Università degli Studi di Parma, MARTA KOPACZYŃSKA, CARLOS BUSTAMANTE, ALEX ZETTL, University of California, Berkeley — The lateral spatial resolution of modern atomic force microscopy (AFM) is largely limited by the radius of curvature of the probe. Owing to their extraordinary mechanical strength, large aspect-ratio, and sub-nanometer radius, carbon nanotubes (CNTs) have emerged as the ideal AFM probe tip material, yet existing methods for CNT-AFM probe fabrication have not been optimized. In this work, we present a fabrication method that yields direct control over the CNT's length, radius, and tilt angle by using a positioning stage operated in a transmission electron microscope (TEM) to directly attach a single-walled CNT to the apex of an AFM probe tip. The CNT probes are then utilized to image gold nanoparticles and DNA with tapping-mode AFM in ambient conditions. While imaging gold nanoparticles, we report a full-width radius dilation of 5.5 Å and nearly 8 nm resolution enhancement compared to commercially available super sharp Si AFM probes. We also measure a DNA fullwidth of less than 5.0 nm and observe, in some cases, the fine structure associated with the DNA double-helix with a pitch of 3.32 nm, which agrees well with the theoretical value of 3.4 nm.

S1.00121 Experiments in NMR Force Microscopy¹, ISAAC MANZANERA, University of Texas at Austin. Department of Physics, ROSA CARDENAS, Sandia National Laboratories at Livermor, JEREMY PASTER, AMANDA TURBYFILL, JOHN MARKERT, University of Texas at Austin. Department of Physics — We report details of the construction and use of three nuclear magnetic resonance force microscopy (NMRFM) probes, as well as the development of control systems for three-dimensional nanoscale imaging and spectroscopy. Our variable temperature probe performed position-dependent ¹H NMR force measurements on a 25x15x7 μm^3 single crystal of ammonium sulfate $(\text{NH}_4)_2\text{SO}_4$ at room temperature in a sample-on-oscillator geometry. Force signals were detected with a signal-to-noise ratio of 6, and 12 μm resolution, in a one-dimensional scan. Measurements of NMR relaxation times $T_2^* = 1.5 \pm 0.2 \mu\text{s}$, $T_2 = 44 \pm 2 \mu\text{s}$, and $T_1 = 5.6 \pm 0.7 \text{ s}$ were obtained. We describe the upgrade of our ³He NMRFM probe for measurements towards the base temperature of 0.3K for investigation of nanoscale structures and metal oxide interfaces using the iOSCAR technique and perpendicular-cantilever geometry. Force-detected ¹¹B NMR signals in a 30 μm crystal of superconductor MgB_2 have also been achieved using this probe. Efforts in the development of our NMRFM probe for the study of biological samples in liquid media are reported. Magnetic field effects on micromagnet films on cantilevers are being studied for the characterization of the mechanical sensors to be used in these liquid experiments.

¹This work was supported by NSF Grant No. DMR-0605828 and Welch Grant No. F-1191

S1.00122 A Technique for In Situ Ballistic Electron Emission Microscopy, ROBERT BALSANO, College of Nanoscale Science and Engineering, University at Albany, SUNY, Albany, New York 12203, USA, JOHN GARRAMONE, Dept of Materials Science & Engineering, McCormick School of Engineering & Applied Science, Northwestern University, Evanston, IL 60208-3108, USA, VINCENT LABELLA, College of Nanoscale Science and Engineering, University at Albany, SUNY, Albany, New York 12203, USA — Ballistic electron emission microscopy (BEEM) is a scanning tunneling microscopy (STM) technique that can measure transport of hot electrons through materials and interfaces with high spatial and energetic resolution. BEEM requires an additional contact to ground the metal base layer of a metal semiconductor junction. Performing BEEM *in situ* with the sample fabrication requires a custom built STM or modifying a commercial one to facilitate the extra contact, which leaves the technique to highly trained experts. This poster will describe our work to develop a special silicon substrate that has the extra contact built in to enable *in situ* BEEM without modifications to the STM. Electrically isolated contact traces are lithographically patterned *ex situ* onto the silicon substrate and connected to the BEEM sample plate which is then inserted into the ultra-high vacuum chamber. The metal is then deposited through a shadow mask and then mounted *in situ* onto the STM for BEEM measurements. BEEM measurements comparing both *in situ* and *ex situ* deposited films will be presented.

S1.00123 Nano and Micro Structures Image Based on Lens-Crystal System For Hard X-Ray Radiation, DAVID KUYUMCHYAN, California State University, Northridge, CA 91330, USA, ARMEN KUYUMCHYAN, American NanoScience and Advanced Medical Equipment, INC, CA 91204, USA, VICTOR KOHN, National Research Center "Kurchatov Institute", 123182, Moscow, Russia, ANATOLY SNIGIREV, IRINA SNIGIREVA, European Synchrotron Radiation Facility, B.P. 202, F - 38043 Grenoble, France, EVGENY SHULAKOV, Institute of Microelectronics Technology, RAS, 142432, Chernogolovka, Russia, CALIFORNIA STATE UNIVERSITY, NORTHRIDGE COLLABORATION, AMERICAN NANOSCIENCE AND ADVANCED MEDICAL EQUIPMENT, INC, CA 91204, USA COLLABORATION, NATIONAL RESEARCH CENTER "KURCHATOV INSTITUTE" COLLABORATION, EUROPEAN SYNCHROTRON RADIATION FACILITY, B.P. 202, F - 38043 TEAM, INSTITUTE OF MICROELECTRONICS TECHNOLOGY, RAS, 142432, CHERNOGOLOVKA, RUSSIA COLLABORATION — We present results of imaging properties of the lens-crystal system for hard x-ray radiation. The system is based on a beryllium parabolic refractive lens placed in front of the sample, and an asymmetric silicon single crystal placed behind the sample. We record the magnified x-ray phase contrast image at the x-ray energy 15 keV. The peculiarities of image transformation are investigated both experimentally and theoretically when the focus of refractive lens is moved across and along the optical axis. The computer program was elaborated for a simulation of image formation in the system based on the refractive lens and the crystal with asymmetric Bragg diffraction. The algorithm is based on the FFT procedure.

S1.00124 High Throughput Tomography at the Advanced Photon Source 2BM Beamline enabling the Study of the Morphological Changes in MgH₂ Destabilized LiBH₄ Systems¹, TABBETHA DOBBINS, Rowan University, SHATHABISH NARASEGOWDA, Louisiana Tech University — Understanding morphologies in two phase hydride systems, such as MgH₂ and LiBH₄ mixtures, will permit the study of mass transport (i.e. diffusion), interface reaction (i.e. H₂ desorption reactions) and ultimately models for H₂ desorption and uptake rates. Many hydride systems are prepared by high energy ball milling which delivers stochastic microstructures from which many images are needed in order to collect reliable particle size and interfacial area data. The high throughput tomographic imaging system at 2BM of the Advanced Photon Source permitted data collection from a series of mixed hydrides—with the goal of optimizing energy for absorption contrast from a two phase system and determining relative amounts of hydride phase as well as interfacial area between the hydrides. Two-phase mixtures at LiBH₄:MgH₂ ratios of 1:3, 1:1, and 2:1 were imaged. The optimal energy for measurement was determined to be 15 keV (having 18% transmission for the MgH₂ phase and above 90% transmission for the LiBH₄ phase). Results showed that the % of interfacial area for the mixed composite system was always higher in the catalyzed system—increasing from 15% to 34% in the 1:3 system, from 27% to 60% in the 1:1 system, and 22% to 37% in the 2:1 system.

¹Funding for this project was provided by the National Science Foundation (NSF) CAREER Award, Ceramics Program (Contract # DMR-0847464). Use of the APS was supported by the USDOE, Office of Science (BES Contract # DE-AC02-06CH11357).

S1.00125 A study of biofunctionalized silica nanospring surface for immunosensor applications, YUKTA P. TIMALSINA, DAVID N. MCILROY, University of Idaho — A study of biofunctionalized VANS (vertically aligned (silica) nanospring) surface for immunosensor applications is presented. VANS surface treated with 3-aminopropyltriethoxysilane (APTES) leaves a primary amine groups on the VANS surface. Glutaraldehyde (GA) reacts with APTES modified VANS surface forming imine bonds at one end of glutaraldehyde, leaving aldehyde groups at the other end to react with the antibody. X-ray photoelectron study verifies each step of VANS surface functionalization. A goat anti mouse antibody (GαM IgG I) is immobilized as a biorecognition layer on the APTES-GA modified surface and targeted to mouse IgG. It is investigated that mouse IgG captured from the solution phase specifically binds to goat anti mouse IgG on APTES-GA- GαM IgG I. Then layer of GαM IgG II attached to the APTES-GA- GαM IgG I-mouse IgG surface reacts only when there is mouse IgG instead of rabbit IgG. A modeling of a resistor-inductor-capacitor (RLC) circuit of impedance spectra measured after the addition of successive layer indicates the these biological layers behave as insulating layers. It is explored that there is a greater magnitude of change between successive bio-layers below 10 kHz. Changes in the magnitudes of the elements of the RLC equivalent circuit indicate that the addition of biological layers impedes ionic motion thereby changing the effective dielectric response by the biomolecule polarization.

S1.00126 Terahertz detection of nanorectifiers, SHAHRIR R. KASJOO, CLAUDIO BALOCCO, XIAOFENG F. LU, LINQING Q. ZHANG, YASAMAN ALIMI, School of Electrical and Electronic Engineering, University of Manchester, Manchester M13 9PL, U.K, STEPHAN WINNERL, Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany, AIMIN M. SONG, School of Electrical and Electronic Engineering, University of Manchester, Manchester M13 9PL, U.K — Despite of a broad range of applications in the terahertz (THz) region, there is still a lack of compact, low-cost, solid-state devices that can function at room temperature. Here we report on THz detection by a novel type of unipolar nanodiode, known as self-switching diode (SSD), which is realized by breaking the symmetry of a nanochannel. The SSD has a completely different working principle from conventional diodes since it does not rely on any doping junction or Schottky barrier. Its intrinsically low parasitic capacitance enables electrical rectification at ultrahigh speed. In this report, the SSDs are coupled with standard bow-tie antennas. The THz signals are generated by means of a free-electron laser, at several THz frequencies ranging from 1.3 THz to 2 THz. The THz detection measurements were carried out at room temperature and 20 K. We find that the highest estimated voltage sensitivity achieved at room temperature and 20 K operations are around 390 mV/mW and 46 V/mW, respectively. For detection at room temperature, this is the highest speed reported in nanorectifiers to date. Furthermore, we also observe evidence of THz detection enhancement by localised plasma oscillation before the cut-off frequency as reported in the Monte-Carlo simulations.

S1.00127 Characterization of Solar Cells via LED Spectrophotometer with Consideration of Spatial and Spectral Distributions of the LED Light Sources, JAEHYEONG LEE, NCSSM, ROB GOURLEY, SIIB, SANGMIN LEE, LSL — Fast and cheap spectral response measurement systems are required in solar cell manufacturing lines in order to produce high quality solar cells. Using LEDs as light sources is the most promising technique. However, since LEDs inherently have 10 - 15 nm spreads in wavelength, the resolution for the wavelength is about 10 times worse than conventional spectrophotometers. In this report, a method to compensate for the wavelength spread of LEDs

has been developed. The output power from a solar cell can be expressed as, $P_{out} = \int P_{in}(\lambda) \times \varepsilon(\lambda) d\lambda \cong \int P_{in}(\lambda) \times \sum_{i=0}^n a_i \times \lambda^i d\lambda$, where $P_{in}(\lambda)$ is the

distribution function of LED light power, $\varepsilon(\lambda)$ is the efficiency of a solar cell, λ is the wavelength and a_i is the coefficient of an n^{th} order polynomial approximation of $\varepsilon(\lambda)$. Since 8 different wavelength LEDs were used, the maximum value of n is 7. With the same method, quantum efficiency was also approximated. Two different sizes of Si single crystal solar cells were examined with this method. For the larger solar cell, the effect of spatial distribution of LED light intensity was also calibrated. By comparing the data from larger solar cell with existing data sheet, it was confirmed that the solar cell efficiency can be accurately measured by an LED spectrophotometer without assuming monochromatic light sources.

S1.00128 Simulation and Modeling of charge particles transport using SIMION for our Time of Flight Positron Annihilation Induce Auger Electron Spectroscopy systems¹, PRASAD JOGLEKAR, K. SHASTRY, SUMAN SATYAL, ALEXANDER WEISS², University of Texas at Arlington — Time of flight Positron Annihilation Induced Auger Electron Spectroscopy system, a highly surface selective analytical technique using time of flight of auger electron resulting from the annihilation of core electrons by trapped incident positron in image potential well. We simulated and modeled the trajectories of the charge particles in TOF-PAES using SIMION for the development of new high resolution system at U T Arlington and current TOFPAES system. This poster presents the SIMION simulations results, Time of flight calculations and larmor radius calculations for current system as well as new system.

S1.00129 Solar cell evaluation using electron beam induced current with the large chamber scanning electron microscope, TARA WINK, EDWARD KINTZEL, Western Kentucky University, PETER MARIENHOFF, MARTIN KLEIN, Ellcie Maintenance GmbH — An initial study using electron beam induced current (EBIC) to evaluate solar cells has been carried out with the large chamber scanning electron microscope (LC-SEM) at the Western Kentucky University Nondestructive Analysis Center. EBIC is a scanning electron microscope technique used for the characterization of semiconductors. To facilitate our studies, we developed a Solar Amplification System (SASY) for analyzing current distribution and defects within a solar cell module. Preliminary qualitative results will be shown for a solar cell module that demonstrates the viability of the technique using the LC-SEM. Quantitative EBIC experiments will be carried out to analyze defects and minority carrier properties. Additionally, a well-focused spot of light from an LED mounted at the side of the SEM column will scan the same area of the solar cell using the LC-SEM positioning system. SASY will then output the solar efficiency to be compared with the minority carrier properties found using EBIC.

S1.00130 SUPERLATTICES, NANOSTRUCTURES, AND OTHER ARTIFICIALLY STRUCTURED MATERIALS —

S1.00131 Circular dichroism in double layer metallic crossed-gratings, WENSHENG GAO, HO MING LEUNG, Physics Department, HKUST, YUNHUI LI, HONG CHEN, Pohl Institute of Solid State Physics, Tongji University, Shanghai, WINGYIM TAM, Physics Department, HKUST — We report on the fabrication of double layer gold crossed-gratings consisting of a top convoluted layer of gold grating over a bottom gold grating using an e-beam direct write technique together with a lift-off process. The crossed-gratings exhibit, in the visible range, strong circular dichroism which is dependent upon the incident direction due to the convoluted top gold grating and also the conducting substrate. Resonance dips in the transmittance of circularly polarized light are also observed. The experimental results are explained qualitatively by simulations using a finite-integration technique. The simulations confirm that the dips in the transmittance are electromagnetic resonances corresponding to parallel and anti-parallel current flows in the crossed-gratings. (Accepted by J.Opt)

S1.00132 Enhancement of magnetic moment in powder Mn₁₁Si₁₉, KIYOTAKA HAMMURA, Hitachi Cambridge Laboratory, University of Cambridge, HARUHIKO UDONO, TOMOSUKE AONO, Ibaraki University — Higher-manganese silicides (HMSs), having a formula of MnSi_{1.75-x}, have drawn much attention in terms of future spintronics materials, following provisional findings of ferromagnetism in them. However, their magnetic properties have still been controversial. In this paper, magnetic moment in Mn₁₁Si₁₉ was measured at temperatures 5K to 290K, both in bulky and in powdery state. The bulk specimen was carefully prepared using a temperature gradient solution growth (TGSG) method and confirmed to be of single crystal by x-ray characterisation. It was found that Mn₁₁Si₁₉ had paramagnetism. Moreover, its magnetic moment was enhanced from 0.16 Wb m/ μ_B to 0.22 Wb m/ μ_B by changing its structure from bulky and powdery, respectively.

S1.00133 Blue Afterglow from ZnS:Ag,Co Water Soluble Nanoparticles, LUN MA, XIAOJU ZOU, MARIUS HOSSU, WEI CHEN, UT Arlington — Blue afterglow has been obtained from water soluble ZnS:Ag,Co nanoparticles by using a simple wet chemistry synthesis. The nanoparticles have a cubic zinc blende structure with average sizes of about 4 nm as determined by high-resolution transmission electron microscopy (HRTEM) and X-ray diffraction (XRD). The blue emission peaked at 441 nm is due to the transition from surface defects to Ag⁺ luminescent centers. However, the afterglow from ZnS:Ag,Co nanoparticles is centered at 475 nm. The presence of Co²⁺ is necessary to obtain the afterglow. The X-ray photoelectron spectroscopy (XPS) measurement indicates that oxidation occurred on the particle surfaces is also important. The blue afterglow ZnS:Ag,Co nanoparticles may open new applications in biological imaging, detection and treatment.

S1.00134 Magnetic and structural properties of ferrofluids based on Cobalt-Zinc ferrite nanoparticles¹, P. PRIETO, J. LOPEZ, M.E. GOMEZ, J. PRADO, J. CAICEDO, G. ZAMBRANO, CENM Universidad del Valle, L. GONZALEZ, Depto Química Universidad del Valle, J. ESTEVE, Universitat de Barcelona, Catalunya, Spain — Ferrofluids are colloidal systems composed of a single domain of magnetic nanoparticles with a mean diameter around 10 nm, dispersed in a liquid carrier. Magnetic Co_(1-x)Zn_xFe₂O₄ ferrite nanoparticles were prepared via co-precipitation method from aqueous salt solutions in an alkaline medium. The composition and structure of the samples were characterized through EDX and XRD, respectively. Transmission Electron Microscopy studies permitted determining nanoparticle size. Grain size of nanoparticle conglomerates was established via Atomic Force Microscopy. The magnetic behavior of ferrofluids was characterized by Vibrating Sample Magnetometer; and finally, a Magnetic Force Microscope was used to visualize the magnetic domains of nanoparticles. The mean size of the crystallite of nanoparticles determined by using the Scherrer approximation diminished when the Zn concentration increases. The size of the nanoparticles obtained by TEM is in good agreement with the crystallite size calculated from XRD measures. The magnetic properties investigated at room temperature presented super-paramagnetic behavior, determined by the shape of the hysteresis loop. Finally, our magnetic nanoparticles are considered a soft magnetic material.

S1.00135 Magnetic Quenching of Plasmon-photonic Activities in Fe₃O₄-Elastomer Composite¹, DUSTIN HESS, DANHAO MA, DEREK CAPLINGER, KOFI ADU, Department of Physics, The Pennsylvania State University, Altoona College, Altoona, PA 16601, USA, RICHARD BELL, Department of Chemistry, The Pennsylvania State University, Altoona College, Altoona, PA 16601, USA — We present preliminary results on the effect of particle size on the optical response of Fe₃O₄-silicone elastomer composite in the presence of external static magnetic field. The optical response of composites containing 2wt% of Fe₃O₄ particles of diameter range 20-30nm, 40-60 nm and d<500nm in silicone elastomer were measured using a PerkinElmer lambda 950 UV/vis/NIR spectrometer. We observed a systematic redshift in the optical response of composites containing nanoparticles (20nm-30nm and 40-60nm) with increasing static magnetic field strength, which saturates near 600 Gauss. However, we observed a dramatic suppression to near quenching of the plasmonic activities in the micron size particle (d < 500nm) elastomer composites. This occurred even at very low applied static magnetic fields, suggesting particle size limitations in modulation of plasmon-photonics by external magnetic field.

¹This Work is Funded by Penn State Altoona Undergraduate Research Grant.

S1.00136 Photo-Switching of Magnetization in Iron Nanoparticles, NABIL AL-AQTASH, ALEXANDER HOSTETTER, RENAT SABIRIANOV, University of Nebraska at Omaha — We report the theoretical studies of light induced switching in core-shell nanoparticles. The core of the nanoparticle is made of Fe coated with the shell of azobenzene. The latter is a photochromic material with the reversible *trans-cis* photoisomerization upon irradiation by UV and visible light. The magnetization of nanoparticles can be reversibly switched by using specific wavelengths of light. *trans-cis* photoisomerization of azobenzene induces both the change in surface local magnetic moments and alters the exchange interactions on the surfaces of the nanoparticles. These two mechanisms can lead to induced magnetization switchable by light pulse. We study the effects of photoisomerization of azobenzene on iron (Fe) nanoparticle. Ab initio calculations using SIESTA code show that the ferromagnetic (FM) and antiferromagnetic (AFM) exchange interaction in Fe dimer increase by 40% due to photoisomerization of azobenzene. While an infinite flat Fe monolayer shows variation on the exchange interactions on the surfaces as result of photoisomerization. The local magnetic moments of Fe sheet increase by 6% due to photoisomerization. Using an *ab initio* parameterization of magnetic interactions, we propose statistical model based on competing exchange interactions for the investigation of Fe nanoparticle magnetization. We performed Monte Carlo simulations of magnetization of the core-shell nanoparticle as a function of temperature. The results show that Fe nanoparticles magnetization at room temperature can change by at least 40% due to photoisomerization of azobenzene.

S1.00137 On the scattering of polarized neutrons by solitons in low dimensional magnetic systems, IRINA BARIAKHTAR, Boston College, VICTOR BARIAKHTAR, Institute of Magnetism, Kyiv, Ukraine, ALEXANDER NAZARENKO, Acceletech, Framingham, MA — The cross section of the scattering of polarized neutrons by solitons in low dimensional systems with the magnetic structure is calculated. The authors consider solitons corresponding to the formation of a kink in a system of adatoms on the surface of a substrate or a crowdion in a chain of atoms in crystals described by the sine-Gordon equation, a breather with zero topological charge, and also solitons in a bound electron-phonon quasi-one-dimensional molecular chain. It is shown that study of the polarized neutrons scattering provides the possibility to investigate the static and dynamic properties of the solitons. In addition, the information obtained from the neutron scattering allows for experimental reconstruction of the magnetic momentum distribution in these structures. We suggest that prospective experiments on observing and studying the solitons can deepen the insight into the physics of the strongly correlated systems.

S1.00138 Theory of electrically-tunable coupling between magnetic nanoparticles on graphene, HUA CHEN, University of Tennessee at Knoxville, University of Texas at Austin, QIAN NIU, University of Texas at Austin, ZHENYU ZHANG, University of Science and Technology of China, Harvard University, University of Texas at Austin, ALLAN H. MACDONALD, University of Texas at Austin — We will present a study of the dependence on graphene carrier density of the coupling between magnetic nanoparticles adsorbed on a graphene sheet. Small system *ab initio* coupling strength results will be compared with semi-analytic results based on a phenomenological Dirac-band model for graphene's π -bands. The model calculation uses kinetic exchange coupling parameters for the interaction between a magnetic nanoparticle and the graphene π -bands that are extracted from *ab initio* results for graphene/ferromagnetic metal interfaces.

S1.00139 Synthesis and thermoelectric properties of PbTe nanostructures¹, KAMAL KADEL, LATHA KUMARI, WENZHI LI, Florida International University — Lead Telluride (PbTe) nanostructures were synthesized via the solvothermal/hydrothermal route. X-ray diffraction (XRD), scanning electron microscopy (SEM), and transmission emission microscopy (TEM) were used to characterize the as-prepared samples and indicated that the PbTe nanoparticles were cubical in shape and had face centered cubic structure. The effects of the addition of surfactants on the shapes and sizes of the nanocubes were investigated. PbTe nanocubes synthesized with the addition of surfactants showed uniform well-defined shapes. The effect of the synthesis temperature on the structure and morphology was also investigated; it was found that the particle size increased with the synthesis temperature. Thermoelectric property of the as-synthesized PbTe nanostructures was also investigated.

¹This work is supported by the National Science Foundation under the grant DMR-0548061.

S1.00140 Ab-initio Calculation of the Magnetic Properties of BN Nanoribbon¹, JEFF RUFINUS, Widener University, Science Division, Chester, PA 19013 — Recently, the search for new spintronics materials has also included graphene-based materials due to the theoretical prediction that this type of material may show the half-metallic property. Here, we present the results of a density functional theory within a generalized gradient approximation study of narrow Boron Nitride nanoribbon (BNNR). The objective of this study is to determine whether this type of material will be ferromagnetic (FM), antiferromagnetic (AFM), or ferrimagnetic. Our results show that the narrow zigzag shaped BNNR prefers antiferromagnetic state. The energy difference among the three states (FM, AFM, ferrimagnetic), however, is very small. Increasing the width of BNNR, was predicted to cause the stabilization of FM state instead of the AFM state.

¹Work supported by Widener University grants. Computational time from PSC and OSCER-OU is acknowledged.

S1.00141 Ab initio nonadiabatic molecular dynamics of the ultrafast excitation energy transfer in small semiconducting carbon nanotube aggregates, OLENA POSTUPNA, RUN LONG, OLEG PREZHDO, University of Rochester, Rochester, NY — Outstanding physical properties of carbon nanotubes (CNTs), such as well-defined optical resonance and ultrafast nonlinear response, result in CNTs gaining popularity in academic and industrial endeavors as potential effective energy generating devices. Following recent experiments on ultrafast excitation energy transfer in small semiconducting carbon nanotube aggregates [1], we report results of ab initio nonadiabatic molecular dynamics simulation of the energy transfer taking place in two carbon nanotube systems. We investigate the energy transfer between (8,4) and (10,0) CNTs, as well as (8,4) and (13,0) CNTs. In both cases, the CNTs are orthogonal to each other. Luer et al. in [1] elucidate the second excitonic transitions followed by fast intratube relaxation and energy transfer from the (8,4) CNT toward other acceptor tubes. Our project aims to provide a better understanding of the energy transfer mechanism in the given systems, which should foster development of a theory for the electronic structure and dynamics of CNT networks, hence enhancing their tailoring and application in the future. S1.00142 Transport Imaging in the Near-Field Regime for the Determination of Carrier Diffusion Behavior in ZnO and GaN Nanostructures¹, NANCY HAEGEL, Physics Department, Naval Postgraduate School, DANIEL CHISHOLM, Mechanical Engineering Dept., Naval Postgraduate School, LEE BAIRD, R. ADAM COLE, Physics Department, Naval Postgraduate School — Optical imaging of the spatial dependence of recombination luminescence generated at a point source is used to determine minority carrier diffusion lengths in GaN and ZnO nanostructures. By combining the resolution of near-field optics with the localized carrier generation capability of the scanning electron microscope, both diffusion and waveguiding behavior can be directly imaged in a contact-free manner for any luminescent material. This approach has been used to investigate the effect of different shell materials on GaN core/shell nanowires on surface recombination and carrier transport [Baird et. al. Appl. Phys. Lett. 98, 132104(2011)]. In ZnO, transport imaging shows variations in transport behavior depending on growth technique and morphology. Diffusion lengths in excess of 1 μm have been observed in ZnO nanobelts, consistent with reports of low concentrations of point and extended defects in these materials.

S1.00143 Effect of Magnetic-Dielectric Interface on Capacitor Functions of Fe-Doped Barium Titanate Nanocomposites at Low Frequency (< 1 MHz), ATAUR CHOWDHURY, University of Alaska Fairbanks, KAPIL KULKARNI, NanoLab, Inc., Newton, MA, GAUTAM SARKAR, US Department of Defense — Metal-dielectric interfaces have been shown to greatly influence the capacitor functions of nanodielectric composites. However, the effect of magnetic metal impurities in nanocomposites on dielectric properties is not well understood. Nanodielectric composites of iron in off stoichiometric barium titanate were fabricated by sol-gel process with varying pH concentrations. The fabricated samples containing 1-2% iron reveal unique interfacial structure as studied by X-ray and atomic force microscopy. The capacitance of the as prepared samples was measured with an Agilent LCR meter at frequencies ranging from 20 Hz to 1 MHz. All nanodielectric composites show similar capacitor characteristic and reveal continuous decrease in capacitor density with increasing frequency. For a particular sample, this continuous decrease is a direct result of the porous interface between the iron granules and the dielectric material. This behavior, however, is not measurably influenced by an applied magnetic field in all samples.

S1.00144 Spin dependent thermoelectric effect in magnetic tunnel junctions, LAURENT CHAPUT, Institut Jean Lamour, WEIWEI LIN, universite paris sud, MICHEL HEHN, Institut Jean Lamour, BEATRICE NEGULESCU, CNRS-CEA, STEPHANE ANDRIEU, FRANCOIS MONTAIGNE, STEPHANE MANGIN, Institut Jean Lamour — Thermoelectric effects in magnetic nanostructures and the so-called spin caloritronics are attracting much interests. Indeed it provides a new way to control and manipulate spin currents which are key elements of spin-based electronics. Here we report on the magneto thermoelectric effect in a magnetic tunnel junction. The thermovoltage in this geometry can reach 1 mV. Moreover a magneto-thermoelectric effect could be measured with ratio similar to the tunnel magnetoresistance ratio. The Seebeck coefficient can then be tuned by changing the relative magnetization orientation of the two magnetic layers in the tunnel junction. Therefore our experiments extend the range of spintronic devices application to thermoelectricity and provide a crucial piece of information for understanding the physics of thermal spin transport.

S1.00145 Enhanced thermoelectric properties using modulation-doping strategy in nanocomposites¹, MONA ZEBARJADI, MIT, BO YU, ZHIFENG REN, Boston College, MILDRED DRESSELHAUS, GANG CHEN, MIT, S3TEC TEAM — We introduce the modulation-doping strategy in bulk SiGe nanostructures to improve the thermoelectric power factor. By separating carriers from their parent atoms via embedding heavily doped nanoparticles inside a host matrix, the ionized impurity scattering rate could be largely reduced, resulting in enhanced mobility. By band engineering, the carriers can spill over from nanoparticles into the host matrix, resulting in similar carrier concentrations, Fermi levels and consequently Seebeck coefficients as those of the uniform nanocomposites. In addition, nanoparticles with low thermal conductivities can further reduce the overall thermal conductivity of the sample. Combining the enhanced electrical conductivity, the reduced thermal conductivity and the unaffected Seebeck coefficient, we were able to enhance the thermoelectric properties of Ge-dilute Si95Ge5. And therefore were able to fabricate a low-cost sample with a competitive performance as those of the state of the art Si80Ge20. The fabricated modulation-doped sample has a higher figure of merit, compare to its equivalent uniform nanocomposite sample and compare to ionized impurity-doped host matrix.

¹This presentation is based upon work supported as part of the MIT S3TEC, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science.

S1.00146 Ternary p-type half-Heuslers: another perspective bulk thermoelectrics, XIAO YAN, WEISHU LIU, HUI WANG, DEZHI WANG, Boston College, GANG CHEN, MIT, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, MIT COLLABORATION — By employing the nanocomposite approach, we have achieved peak ZT of 0.8 at 700 °C for p-type $\text{Hf}_{0.5}\text{Zr}_{0.5}\text{CoSb}_{0.8}\text{Sn}_{0.2}$. A larger difference in atomic mass and size of Hf and Ti than Hf and Zr in the crystal structure has produced a peak ZT of ~ 1.1 at 800 °C for p-type $\text{Hf}_{0.8}\text{Ti}_{0.2}\text{CoSb}_{0.8}\text{Sn}_{0.2}$. However the ZT peak is on the high temperature side. A ternary combination of Ti, Zr, and Hf at M site (MCoSb) has given rise to higher ZT in n-type MnInSn system. Will ternary on the M site yield better ZT for p-type? In this report, we will present our recent achievement of 10-25% ZT improvement for temperature range 25-700 °C without sacrificing the peak ZT value of 1.1 at 800 °C.

S1.00147 Potassium resonant doping in $\text{Bi}_{92.5}\text{Sb}_{7.5}$ material, HUAIZHOU ZHAO, MANI POKHAREL, CYRIL OPEIL, Department of Physics, Boston College, GANG CHEN, Department of Mechanical Engineering, Massachusetts Institute of Technology, ZHIFENG REN, Department of Physics, Boston College, REN'S LAB AT BOSTON COLLEGE COLLABORATION, GANG CHEN'S LAB AT MIT COLLABORATION — $\text{Bi}_{1-x}\text{Sb}_x$ alloy material is a narrow band semiconductor when x is in the range of 0.07 – 0.4. The energy gap reaches a maximum value of 0.014 eV in the composition range of $x = 0.15$ to 0.2. Thermoelectric properties on this material have been investigated for half a century due to the promising cooling applications. However, the low efficiency originating from the medium thermoelectric Power Factor (PF) prohibited this material from real applications. Here, we demonstrated that by potassium doping, both the Seebeck Coefficient and electrical conductivity can be enhanced by 25% for the ingot samples for a broad temperature range. Further more, by combining with our nano grain size approach, thermal conductivity of ingot sample was reduced by 20%, this lead to the figure of merit ZT increase of 50% comparing to ingot counterpart. The potassium resonant doping was accounted for the PF enhancement for ingot $\text{Bi}_{92.5}\text{Sb}_{7.5}$ sample. We also find that the resonant doping can be realized for nano composite samples through parameters optimization.

S1.00148 Simple solvothermal synthesis of large scale single crystal PbS nanorods and their properties, SYAMANTA KUMAR GOSWAMI, EUNSOON OH, Chungnam National University — PbS nanorods and quantum dots have lots of applications such as in solar cells, gas sensors, infra-red detectors etc. PbS nanorods were synthesized via a very simple and inexpensive solvothermal method. Two reagents viz. Ethylenediaminetetraacetic acid (EDTA) and PEG-PPG-PEG triblock copolymer (P123) were employed in this growth for two special purposes. EDTA helps in slowing down the reaction and P123 plays the role of 1D structure directing agent. Comparison of the X-ray diffraction patterns of the nanowires synthesized using EDTA and without using EDTA clearly shows that the crystalline quality is significantly improved with EDTA. Transmission Electron Microscopy images and Selected Area Electron Diffraction patterns demonstrate that the nanorods are single crystalline. The average diameter of the nanorods was found to be about 18 – 20 nm. Thus, the nanorods are within the quantum regime as the exciton Bohr radius of PbS is 18 nm. Raman spectra of these samples are compared.

S1.00149 Superlattice formed by quantum dot sheets: density of states and IR absorption¹, VLADIMIR MITIN, FEDIR VASKO, Electrical Engineering Department, University at Buffalo, SUNY — Low-energy electronic states in heterostructures formed by periodically placed quantum dot (QD) sheets are studied taking into account (i) ultranarrow (single or several monolayers thickness) wetting layers and (ii) scattering by randomly-placed QDs. The host material is described within the effective mass approximation, scattering by the QD sheets is governed by the periodical Dyson equation, and effect of wetting layers is taken into account within the transfer matrix approach. Using the current conservation and inversion symmetry requirements, the transfer matrix is evaluated beyond effective mass approximation. The binding energy of localized state, the reflection (transmission) coefficient for the single QD sheet case, and the energy spectrum of superlattice are determined for the case of GaAs host matrix with InAs QD sheets. Spectral dependency of mid-IR absorption in superlattice due to photoexcitation of electrons from localized states into minibands is determined by the QD's concentration, period of sheets, and wetting layer characteristics. Such a dependency modifies the characteristics of optoelectronic devices based on heterostructures with QD sheets.

S1.00150 Voltage-tunable IR photodetector based on asymmetrically doped coupled quantum wells¹, JAE KYU CHOI, NIZAMI VAGIDOV, ANDREI SERGEEV, GOTTFRIED STRASSER, FEDIR VASKO, VLADIMIR MITIN, Electrical Engineering Department, University at Buffalo, SUNY — We report on the mid-IR two-color photodetector with spectral photoresponse tunable by biased voltage. The device is based on GaAs/AlGaAs asymmetrically doped coupled quantum well structures grown by molecular beam epitaxy. A single unit of the detector is composed of 6.5 nm-thick GaAs layer doped with Si up to $5 \times 10^{11} \text{ cm}^{-2}$ and 6.5 nm-thick undoped GaAs separated by 3.1 nm-thick $\text{Al}_{0.2}\text{Ga}_{0.8}\text{As}$. Units are separated by 50 nm-thick $\text{Al}_{0.2}\text{Ga}_{0.8}\text{As}$ barriers. Our devices consist of 25 identical units. We demonstrated that in temperature range 20 - 70 K the peak detection wavelengths can be switched from $7.5 \mu\text{m}$ to $11.1 \mu\text{m}$ by varying bias from -5 V to +5 V. Our modeling shows that spectral tunability is basically determined by three factors. First, electron energy levels are shifted due to Stark effect. Second, electric field leads to the charge redistribution in the coupled wells and electron energy levels are shifted by electron-electron interaction. Third, tunneling processes from photoexcited quasi-localized electron states in wells to conducting states are enhanced in the electric field due to Fowler-Nordheim effect. The modeling results are in very good agreement with the experimental data. The proposed detectors are promising candidates for adaptive tunable sensing in the IR range.

S1.00151 Analytical minimization of total spread of generalized Wannier functions in one-dimensional crystals¹, DENIS R. NACBAR, ALEXYS BRUNO-ALFONSO, Universidade Estadual Paulista, Brazil — Since their introduction in 1937, Wannier functions have become key theoretical and computational tools in Solid State Physics. In this work, generalized Wannier functions of several bands in a one-dimensional crystal are investigated. For the case of two bands, necessary condition for minimum of total variance leads to a non-linear set of four second-order differential equations having a simple analytical solution. This is a new alternative to current iterative numerical procedures. Results are displayed for diatomic crystals with inversion symmetry. The relation between generalized Wannier functions and orthogonalized atomic orbitals is discussed. It is shown that such functions may present increased exponential localization when compared with Wannier functions of separate bands. Our findings should be relevant in studies of layered semiconductor and photonic structures and linear atomic chains. Hopefully, it will speed progress both in understanding and applications of Wannier functions.

¹We thank Brazilian Agencies CNPq and FAPESP for financial support.

S1.00152 Capacitively coupled double quantum dot system in the Kondo regime¹, EDSON VERNEK, IRISNEI FERREIRA, Universidade Federal de Uberlândia - Brazil, PEDRO ORELLANA, Universidad Catolica del Norte - Chile, GEORGE MARTINS, Oakland University - USA, FABRICIO SOUZA, Universidade Federal de Uberlândia - Brazil — We present a detailed study of the low-temperature physics of an interacting double quantum dot system in a T-shape configuration is presented. Each quantum dot is modeled by a single Anderson impurity and we include an inter-dot electron-electron interaction to account for capacitive coupling that may arise due to the proximity of the quantum dots. By employing a numerical renormalization group approach to a multi-impurity Anderson model, we study the thermodynamical and transport properties of the system in and out of the Kondo regime. We find that the two-stage-Kondo effect reported in previous works is drastically affected by the inter-dot Coulomb repulsion. In particular, we find that the Kondo temperature for the second stage of the two-stage-Kondo effect increases exponentially with the inter-dot Coulomb repulsion, providing a possible path for its experimental observation.

¹We would like to thank FAPEMIG and CNPq for financial support.

S1.00153 Electrical Characterization of a Hybrid 1D-0D System of Quantum Dot Chains¹, THOMAS REMBERT, VASYL KUNETS, GREGORY SALAMO, Institute for Nanoscience & Engineering, University of Arkansas — Recent developments in the area of material science and nanotechnology open new horizons to fabricate novel artificial materials with the possibility to engineer the electron and phonon material properties. Our objective is to create structures with high electrical conductivity and low thermal conductivity. The outcome will allow efficient transfer of thermal energy into the electrical output. Early theoretical and experimental research indicates that one-dimensional (1D) quantum wires and zero-dimensional (0D) quantum dots can be used to fabricate very efficient thermoelectric devices. This project focuses on the development of artificial material systems, called quantum dot chains, where 1D states, which are important for high electrical conductivity, coexist with 0D states, causing efficient acoustic phonon scattering, reducing the thermal conductivity. The samples are InGaAs/GaAs grown using an MBE technique of strain-induced self-assembly. Current analysis of our results shows anisotropies of temperature-dependent measurements of sheet resistance and electron mobility, along with physical characterization via AFM scans. Continued studies of electron and phonon physics in this system will help determine the potential for chains of quantum dots in thermoelectric applications.

¹Supported by the Arkansas Department of Higher Education and NSF EPSCoR, VICTER Project (No. EPS1003970).

S1.00154 Tunable Quantum Phase Transition in a Dissipative Resonant Level¹, D.E. LIU, H. ZHENG, H.T. MEBRAHTU, G. FINKELSTEIN, H.U. BARANGER, Duke University — We show that quantum phase transitions (QPT) exist in a simple dissipative resonant level system. The electromagnetic environment couples both to tunneling processes (characterized by lead resistance R_e) and to voltage fluctuations of the gate (characterized by gate resistance R_g). We bosonize this model and map it to a Tomonaga-Luttinger type model. Using a “Coulomb-gas” RG analysis, we relate our dissipative resonant level model to the double barrier problem in a Luttinger liquid. For the symmetric case and $R_e + R_g > 2h/e^2$, a Kosterlitz-Thouless QPT separates strong-coupling and weak-coupling phases. Interestingly, in the symmetric case, all relevant couplings between tunneling processes and the environment disappear, leading to perfect transmission at $T=0$. A second order QPT is also induced by coupling asymmetry for $R_e + R_g < 2h/e^2$. The two phases correspond to the resonant level merging with the right lead while the left lead decouples, and vice versa.

S1.00155 Effects of intrasubband coupling on the scattering phases and density of states in a quantum wire, VASSILIOS VARGIAMIDIS, Aristotle University, Thessaloniki, Greece, VASSILIOS FESSATIDIS, Fordham University, Bronx, USA, PH. KOMNINOU, Aristotle University, Thessaloniki, Greece — The properties of scattering phases and density of states in a quantum wire with an attractive scatterer are analyzed. We consider two bound states, belonging to different subbands, which couple to a scattering channel and give rise to two Fano resonances. It is shown that varying the parameters of the scatterer (such as its strength and position) produces significantly different effects on the phase behavior and density of states, depending on the subband they occur. These effects stem mainly from the difference between the coupling matrix elements of the two resonant levels with the propagating channel mode. As a consequence, the phase evolution in one subband may exhibit opposite behavior from the phase evolution in another subband. These findings may prove experimentally useful in ballistic transport through narrow channels.

S1.00156 Porous silicon nanowire arrays decorated by Ag nanoparticles for surface enhanced Raman scattering study¹, L. SU, H.J. XU, Y.F. CHAN, X.M. SUN, Beijing University of Chemical Technology, STATE KEY LABORATORY OF CHEMICAL RESOURCE ENGINEERING TEAM — A large scale and highly ordered Ag nanoparticle-decorated porous silicon nanowire array was fabricated for a uniform and reproducible surface-enhanced Raman scattering (SERS) substrate. The overall process for the proposed structure is simple and reliable with the use of only chemical etching and metal reduction processes. The SERS sensitivity of the novel substrate as low as 10^{-16} M for rhodamine 6G (R6G) and the Raman enhancement factor as high as 10^{14} were obtained. The excellent SERS performances were mainly attributed to the strong local electromagnetic effect which is associated with the formation of large-quantity Ag nanoparticles on porous silicon nanowire array and the existence of semiconductor silicon nanowires. Significantly, the quadratic relation between the logarithmic concentrations and the logarithmic integrated Raman peak intensities provided quantitative detection of R6G. Our results open new possibilities for applying SERS to trace detection of low-concentration biomolecules.

¹This work was supported by the National Natural Science Foundation of China (Grant No. 11104008), Doctoral Fund of Ministry of Education of China (Grant No. 20090010120014) and the Beijing Natural Science Foundation (Grant No. 1103033).

S1.00157 Atomistic Modeling of Degradation Mechanisms in Nanoscale HEMT Devices, VAMSI GADDIPATI, SASI SUNDARESAN, KRISHNA YALAVARTHI, SHAIKH AHMED, Southern Illinois University — In this work, through atomistic numerical simulations, we investigate how performance degradation of state-of-the-art AlGaIn HEMTs is governed by an intricate coupling of the underlying thermo-electro-mechanical processes while operating at high power and/or high-temperature. The polarization induced charge density is shown to be strongly dependent on the thickness of the AlN barrier layer. This further demonstrates that the degradation in these HEMT devices is related to the reduction of the effective thickness of the AlN barrier layer, which, during operation at high device temperature, could arise from the diffusion of gate metal into the barrier material matrix. This finding has been validated using the massively parallel LAMMPS molecular dynamics tool and available experimental data. We have also demonstrated that the polarization fields alone can induce channel carriers at zero external bias and lead to a significant increase in the ON current.

S1.00158 Electron transport properties in self switching nano-diodes, TATSUYA KISO, KAZUICHI NISHISAKA, TOSHIHIKO MAEMOTO, SHIGEHICO SASA, Osaka Institute of Technology, SEIYA KASAI, Hokkaido University, MASATAKA INOUE, Osaka Institute of Technology — Ultra-fast novel nanodevices, namely the self-switching diode (SSD) were fabricated from the InAs/AlGaSb heterostructures grown by solid-source molecular beam epitaxy on a semi-insulating GaAs (100) substrate. The two lines were etched thorough the 2DEG layer and become insulating. The effective channel width was actually smaller because of the depletion layer at the etched boundaries. Depending on the sign of the applied voltage the effective channel width will increase or reduce, giving rise to the diode-like characteristics. The diode-like characteristics were clearly observed for the InAs SSDs at 300K, and turn on voltage is strongly dependent on the channel width of the SSDs. In the SSD with $W = 460$ nm, the InAs channel of was fully pinched of under the equilibrium condition, and positive voltage of 1.46 V was needed to drive a current thorough the InAs channel. On the other hand, the positive voltage of 2.32 V was needed to drive a current in the SSD with $W = 230$ nm. We found to need the higher the turn-on voltage in the SSD of the narrower channel width. Furthermore, multi-channel SSDs were fabricated. $I - V$ characteristics and the AFM images of the SSD array of the symmetric nanowires, which are $1.5 \mu\text{m}$ long and approximately $W = 170$ nm. The current densities were clearly increased with increasing the number of the nano-wires. The clear diode-like nonlinear behavior and rectification reflected ballistic nature of electrons in InAs-based SSD were observed.

S1.00159 Modeling NIR-to-Visible Upconversion Kinetics in Er^{3+} , Yb^{3+} : NaYF_4 Nanocrystals and Finite-difference Time-domain Simulations of Noble-metal Enhancement Substrates, ROBERT ANDERSON, South Dakota School of Mines and Technology, GE YAO, QUOCANH LUU, University of South Dakota, HARI PAUDEL, KHADIJEH BAYAT, MAHDI BAROUGH, South Dakota State University, CUIKUN LIN, MARY BERRY, STANLEY MAY, University of South Dakota, STEVE SMITH, South Dakota School of Mines and Technology — Upconversion (UC) phosphors are able convert infra-red light to visible wavelengths. The (erbium) Er^{3+} , (ytterbium) Yb^{3+} : NaYF_4 system is the most efficient upconversion phosphor known, and yet the quantitative aspects of the mechanism responsible for upconversion, such as the values of key microscopic rate constants, have not been determined. In this work, the dynamics of the photo-physical processes leading to near-infrared (NIR) to visible upconversion in Er^{3+} , Yb^{3+} : NaYF_4 nanocrystals are investigated using a nonlinear rate-equation model. In tandem with this effort, we use finite difference time domain (FDTD) simulations to analyze noble-metal nanostructures designed to enhance the absorption and emission of the upconverting phosphor. Simulation results are compared with time-resolved luminescence and reflectivity of the plasmonic substrates, which show systematic improvement in fluorescence yield and good agreement with simulated kinetics.

S1.00160 Optical properties of Benzylpiperazine/CuI (111) system¹, TAKAT RAWAL, VOLODYMYR TURKOWSKI, Physics Department and NSTC, University of Central Florida, RICHARD BLAIR, Department of Chemistry and Forensic Science Center, University of Central Florida, TALAT S. RAHMAN, Physics Department and NSTC, University of Central Florida — We are interested in understanding the mechanism responsible for the recently observed [1] strong orange fluorescence in systems that contain Benzylpiperazine (BZP) molecules adsorbed on CuI film. To study possible optical transitions we use ab-initio electronic structure calculations based on density functional theory with the generalized-gradient (PBE) approximation for the exchange-correlation functional. In particular, we examine in detail the band structure including defect states of the CuI film with the lowest energy (111) surface and the excited states of the BZP molecule. It is shown that while optically non-active in the corresponding energy window, the two parts of the system, CuI slab and BZP, produce strong visible light emission when coupled together. Our numerical analysis demonstrates that the reason for such emission is the optical transitions between the excited molecule and the iodine vapor atom states on the CuI (111) surface. We discuss possible applications of the effect and that of defect vapor atom states on other optical properties of the system, including excitonic effects in the ultrafast response. [1] R. Blair, unpublished.

S1.00161 Room temperature sub-diffraction-limited plasmon laser by total internal reflection, RENMIN MA, RUPERT OULTON, VOLKER SORGER, GUY BARTAL, XIANG ZHANG, UC Berkeley — Plasmon lasers are a new class of coherent optical amplifiers that generate and sustain light well below its diffraction limit. Their intense, coherent and confined optical fields can enhance significantly light-matter interactions and bring fundamentally new capabilities to bio-sensing, data storage, photolithography and optical communications. However, metallic plasmon laser cavities generally exhibit both high metal and radiation losses, limiting the operation of plasmon lasers to cryogenic temperatures, where sufficient gain can be attained. Here, we present room temperature semiconductor sub-diffraction limited laser by adopting total internal reflection of surface plasmons to mitigate the radiation loss, while utilizing hybrid semiconductor-insulator-metal nano-squares for strong confinement with low metal loss. High cavity quality factors, approaching 100, along with strong $\lambda/20$ mode confinement lead to enhancements of spontaneous emission rate by up to 18 times. By controlling the structural geometry we reduce the number of cavity modes to achieve single mode lasing.

S1.00162 Probing semiconductor band structures and heterojunction interface properties with ballistic carrier emission: GaAs/Al_xGa_{1-x}As as a model system, WEI YI, VENKATESH NARAYANAMURTI, School of Engineering and Applied Sciences, Harvard University, Cambridge, Massachusetts 02138, USA, HONG LU, MICHAEL A. SCARPULLA, ARTHUR C. GOSSARD, Materials Department, University of California, Santa Barbara, California 93106, USA, HARVARD TEAM, UCSB TEAM — Utilizing tunnel emission of ballistic electrons and holes in a tunnel transistor with a Mott-barrier collector, we have developed a method to self-consistently determine the energy gap of a semiconductor and band offsets at a semiconductor heterojunction without using a priori material parameters. As a model system, electronic band gaps of the AlGaAs alloys together with conduction and valence band offsets at the GaAs/AlGaAs (100) interfaces are measured with a resolution of several meV at 4.2 K. The direct-gap band offset ratio for the GaAs/AlGaAs (100) interface is found to be 59:41. In the indirect-gap regime, ballistic electrons from direct tunnel emissions probe the X valley in the conduction band, while those from Auger-like scattering processes in the metal base film probe the higher-lying L valley. Such selective electron collection may be explained by their different momentum distributions and parallel momentum conservation at the quasiepitaxial Al/GaAs (100) interface. We argue that the present method is in principle applicable to arbitrary type-I semiconductor heterostructures. [W. Yi. at al. Phys. Rev. B 81, 235325 (2010)]

S1.00163 Chaotic dynamics of electron resonant tunneling in a quasi-one-dimensional super-lattice, PAULA FEKETE, US Military Academy, West Point, NY 10966, GODFREY GUMBS, Hunter College at the City University of New York, NY 10065, DANHONG HUANG, Air Force Research Laboratory, Kirtland Air Force Base, NM 87117, OLEKSIY ROSLYAK, Hunter College at the City University of New York, NY 10065 — A novel approach is employed for studying the dynamics of electron resonant tunneling in a quasi-one-dimensional superlattice. The semiclassical force-balance transport equation is used to describe the time-dependence of the dynamical equation for the electron center-of-mass velocity in the presence of an applied DC electric field and two external AC fields. Evolution of phase space trajectories from initial non-equilibrium states is obtained. The attractors of this dynamical system are determined and their stability for different sets of system parameters is obtained. Coupling between the electron's velocity and the external fields gives rise to rich spatiotemporal behavior including chaos.

S1.00164 Cloaking Effect of Superlens in Time Domain, MENG XIAO, The Hong Kong University of Science and Technology, JIAN WEN DONG, Sun Yat-Sen (Zhongshan) University, XUEQIN HUANG, CHE TING CHAN, The Hong Kong University of Science and Technology — A “perfect lens” (ideal absorption-less slab with $\mu = -1$) or “superlens” (a perfect lens with small absorption) can cloak a small object located in its vicinity such that no far field observer can detect the small particle, i.e., being invisible. While the problem is well understood in the steady state by solving the Maxwell equation in frequency domain, its time domain properties, such as how the cloaking effect started, remained unknown. In this paper, by using the time-dependent Green's function approach, we present a time domain study of the cloaking properties of the “superlens” As a current source is turned “on,” the system's response will be consisted of a transient response in the beginning and a steady state response in the long run. It turns out that it takes a long time (tens of thousands of cycle) for the “perfect lens” to build up the cloaking effect, and this required period depends on a number of factors, such as the separation between the lens and the particle, the absorption of the slab, and the dispersion of the slab. Moreover, along with many other interesting effects, we also find that, the dipole moment, on its way to be invisible, it oscillates with a decreasing amplitude.

S1.00165 Quantum mechanical investigation of CO, NO and HCN adsorption on Ag₈ nanoclusters; (structural, electronic and topological properties), HADI AKBARZADEH, ZAHRA TORBATIAN, S. JAVAD HASHEMIFAR, Isfahan University of Technology — We used DFT-GW method to study pure Ag₈ nanocluster and CO, NO, HCN adsorption on it. The pure Ag₈ stabilizes in Td structure and the behavior of binding energy is consistent with the total charge density at bond points while bond length exhibits a behavior similar to the mean bond charge. Adsorption of CO, NO and HCN molecules on different atomic sites of Ag₈ were studied and it was found that all these molecules, mainly due to electron donation, prefer to be adsorbed by LUMO orbital. This finding is in qualitative agreement with the experimental observation of the enhanced binding of CO molecule on positively charged silver atoms, compared with the neutral and negatively charged samples [J. Phys. Chem. A 2006, 110, 7167-7172]. Our calculation shows no significant charge transfer during NO adsorption on Ag₈. The CO, NO and HCN adsorbed nanoclusters as well as cationic and anionic samples do not stabilize in Td structure. This charge induced geometry transition is related to the high (low) value of LUMO (HOMO) state in Td structure which indicates high energy cost of electron donation (acceptation) in this isomer. The topological analysis of electron density clarify that the adsorption energy of molecules on Ag₈ is consistent with the value of the charge density at the topological bond point between molecule and nanocluster.

S1.00166 SURFACES, INTERFACES AND THIN FILMS —

S1.00167 Electronic transport and scanning tunneling microscopy study of bismuth quantum films, SHENGYONG QIN, TAE-HWAN KIM, THOMAS Z. WARD, AN-PING LI, Oak Ridge National Laboratory — Semimetal films, such as bismuth films, have attracted great interest due to their unique electronic properties around the Fermi level. Bulk Bi has three conduction band minima at L points about 40mV lower than the single valance band maximum at T point. However, with decreasing Bi layer thickness, an energy gap is expected to open when the size confinement becomes sufficient to raise the lowest electron subband above the highest hole subband. We have utilized quantum growth method to fabricate atomically flat Bi thin films with thickness controllable down to single atomic layer. The quantum films are then studied in situ with a cryogenic four-probe STM to examine the correlation of the electronic and transport properties. An oscillatory resistivity change is observed as function of film thickness, which is discussed in comparison with the local density of states.

S1.00168 First-order phase transition in In/Si(111)-4×1, JONGHOON YEO, HYUNGJOON SHIM, GEUNSEOP LEE, Department of Physics, Inha University — In/Si(111)-4×1 surface is known to undergo a temperature-induced structural phase transition between a high-temperature (HT) 4×1 phase and a low-temperature (LT) 8×2 phase. The issues on the nature of this temperature-dependent phase transition, whether it is of order-order (displacive) or order-disorder type and first-order or second-order, are unsettled. We investigated the 4×1-to-8×2 phase transition by using LEED and STM. We observed a hysteresis of the LEED beam intensities as the temperature changes during cooling and heating. This hysteresis indicates that the structural phase transition is of first order. STM images revealing the coexistence of the 4×1-HT and 8×2-LT phase domains during the transition are consistent with the first-order transition. An influence of the defects on the phase transition of this In/Si(111) surface will be discussed.

S1.00169 Glancing Angle Deposition of Ag on Si(111)7x7, A.N. COBBLAH, S.T. HAYDEN, YIYAO CHEN, J. KREMENAK, M.W. GRAMLICH, P.F. MICELI, U. Missouri — Ag(111) films were vapor-deposited in ultra-high vacuum on Si(111)7x7 substrates. The angle of deposition was varied from normal incidence to 80 degrees and the films were studied by x-ray reflectivity. It is found that, even for very thin films, the film roughness increased dramatically with the angle of deposition. This poster will highlight experimental results as well as the development of a UHV chamber that enables a laboratory x-ray source to monitor low angle reflectivity during film growth. Funding is acknowledged from the Ronald E. McNair Post-baccalaureate Achievement Program and NSF DMR-0706278. Some measurements were performed on the 6IDC beam line, supported by the US-DOE (through Ames Lab, W-7405-Eng-82), at the Advanced Photon Source (US-DOE, W-31-109-Eng-38) located at Argonne National Laboratory.

S1.00170 Photoluminescence characterization of Cl – doped Cu₂O thin film photoelectrodes¹, WAQQAS KHAN, ROHANA GARUTHARA, Hofstra University — Electrodeposition was used to deposit Cl-doped Cu₂O thin films on ITO substrates. Photocurrent and the Photoluminescence (PL) measurements were done on prepared electrodes. CuCl₂ and different pH values of the solution bath were used to control the doping level in Cu₂O. Photocurrent responses in photoelectrochemical cells clearly showed improved performance over the un-doped Cu₂O thin films as seen by the difference in the light and the dark current. A deconvoluted PL spectra assuming Gaussian spectral profile showed three underlying peaks. The temperature dependence of the peak energy position and intensity was analyzed. Furthermore, the electrodeposition and the nature of the conductivity of the films were also analyzed. These results of the Cl-doped Cu₂O films will be compared with those for the Cu₂O un-doped films and presented.

S1.00171 High transconductance zinc oxide thin-film transistors on flexible plastic substrates, YUTA KIMURA, TOMOHIRO HIGAKI, TOSHIHIKO MAEMOTO, SHIGEHICO SASA, MASATAKA INOUE, Osaka Institute of Technology — We report the fabrication and characterization on high-performance ZnO based TFTs on unheated plastic substrate. ZnO films were grown by pulsed laser deposition (PLD) on polyethylene naphthalate (PEN) substrates. Top-gate ZnO-TFTs were fabricated by photolithography and wet chemical etching. The source and drain contacts were formed by lift-off of e-beam deposited Ti(20 nm)/Au(200 nm). An HfO₂ with thickness 100 nm was selected as the gate insulator, and top gate electrode Ti(20 nm)/Au(200 nm) was deposited by e-beam evaporation. We prepared a set of the structure with SiO₂/TiO₂ to investigate the characteristic changes that appear in the film characteristics in response to bending. From the $I_D - V_{DS}$ and the transfer characteristics which are affected by bending and return for the ZnO-TFT with SiO₂/TiO₂ buffers, the TFTs were bent to a curvature radius of 8.5 mm. The transconductance, g_m is obtained 1.7 mS/mm on flat, 1.4 mS/mm on bending and 1.3 mS/mm on returning the film, respectively. The $I_D - V_{DS}$ characteristics were therefore not changed by bending. All of the devices exhibited a clear pinch-off behavior and a high on/off current ratio of $\sim 10^6$. The threshold voltages, V_{th} were not changed drastically. Furthermore, TFT structures were changed from a conventional top-gate type to a bottom-gate type. A high transconductance of 95.8 mS/mm was achieved in the bottom-gate type TFT by using Al₂O₃ oxide buffer.

S1.00172 Transition Metal Disulfide Films by Reactive Sputtering: Structure, Magnetism, and Electronic Transport, A. BARUTH, M. MANNO, D. NARASIMHAN, A. SHANKAR, X. ZHANG, E. S. AYDIL, C. LEIGHTON, University of Minnesota - Twin Cities — Transition metal disulfides (*i.e.*, TMS_2 , where $TM = Cu, Co, Fe, Ni$, etc.) are a unique class of materials displaying diverse functional properties such as highly spin-polarized ferromagnetism ($Co_{1-x}Fe_xS_2$), superconductivity (CuS_2), a Mott insulating ground state (NiS_2), and unusually high potential for solar absorber applications (FeS_2). Significant research has been performed on bulk crystals of these materials but little has been done on thin films, despite the obvious potential for heterostructured systems due to their diverse functionality and intrinsic epitaxial compatibility. In this work we report on the wide applicability of reactive sputtering from metallic targets in an Ar/H₂S gas environment as a reliable deposition method. Via detailed characterization of crystal structure, microstructure, and electronic, magnetic, and optical properties, we demonstrate successful deposition of a wide variety of single phase polycrystalline thin films with bulk-like properties. A brief survey of optimized growth conditions, resulting physical properties, and general trends based on metal reactivity, will be presented. We argue that this method holds great promise for the synthesis of a novel family of all-sulfide-based heterostructured devices. Work funded by NSF MRSEC and UMN IREE.

S1.00173 Titanium Isopropoxide Precursor Volume Consumption as a Function of Temperature for Titanium Dioxide Thin Films Grown by Atomic Layer Deposition¹, COSTEL CONSTANTIN, James Madison University — Atomic layer deposition (ALD) offers tremendous opportunities for controlling material synthesis on an atomic level and for creating nanolayers with unique new functionalities. ALD is a chemical gas phase thin film deposition method based on alternating surface reactions that employs two or more precursors. ALD is often used for growth of high k dielectric constant oxide films. Titanium dioxide material have a k value of 80, and a band gap of ~ 3 eV, and due to strong oxidizing properties thin films coated on construction materials and glass have fog proof, and self cleaning properties. Our ALD reactor employs liquid Titanium Isopropoxide $[Ti\{OCH(CH_3)_2\}_4]$ as a metal precursor and distilled H₂O as an oxygen source to grow thin films of titanium dioxide $[TiO_2]$ on silicon [Si], gallium nitride [GaN], and Aluminium foil [Al-foil] substrates. Titanium Isopropoxide exhibit a vapor pressure surge above 40° C and we report the volume precursor consumption as a function of precursor temperature and thin film thickness for ALD grown TiO₂ on Si, GaN, and Al-foil substrates. We will also present dielectric constants of the TiO₂ thin films measured with a variable angle spectroscopic ellipsometer.

¹DOD-ASSURE/NSF-REU grant # DMR-0851367

S1.00174 Epitaxial growth of BiFeO₃ thin films on SrTiO₃/Si substrates¹, RYAN LAUGHLIN, DANIEL CURRIE, GOKUL RADHAKRISHNAN, WEERASINGHE PRIYANTHA, ROCIO CONTRERAS-GUERERRO, RAVINDRANATH DROOPAD, NIKOLETA THEODOROPOULOU, Texas State University - San Marcos — We are using molecular beam epitaxy (MBE) to grow BiFeO₃ (BFO) thin films. SrTiO₃ (STO) on Si is used as a virtual substrate to enable the growth of BFO. Commensurate growth of STO on Si using MBE has been achieved by using co-deposition with the fluxes adjusted for stoichiometric growth and the growth rate is determined using RHEED intensity oscillations. The native oxide of the Si substrates is removed in-situ by deoxidation at around 750 °C using a flux of Sr. The substrate is cooled to 500 °C and additional Sr is added to form template with a (2x1) surface structure. BFO is then deposited on well-characterized STO (2-20nm thick) on Si using Fe and oxygen plasma with an overpressure of Bi flux- the growth rate being controlled by the incoming Fe flux. The RHEED pattern taken during deposition of BFO shows 2-D growth front with a 6-fold surface reconstruction. The structural and magnetic properties of the BFO samples have also been measured.

¹This work was supported by AFOSR under grant FA 9550-10-0133

S1.00175 Disorder trapping during crystallization of the B2 ordered NiAl system, DEYAN SUN, XIAOQING ZHENG, YANG YANG, YUFENG GAO, Department of Physics, East China Normal University, Shanghai 200062, China, JEFF J. HOYT, Department of Materials Science and Engineering, McMaster University, Hamilton, ON, Canada, MARK ASTA, Department of Materials Science and Engineering, University of California, Berkeley, CA 94720 — Using molecular dynamics (MD) simulations, disorder trapping associated with solidification is studied for the (100), (110) and (111) growth directions in the B2 NiAl ordered alloy compound. At the high interface velocities studied we observe pronounced disorder trapping, i.e., the formation of antisite defects and vacancies in the crystal at higher than equilibrium concentrations upon rapid solidification. The vacancies are located primarily on the Ni sublattice and the majority of antisite defects are Ni atoms on the Al sublattice, while the concentration of Al on the Ni sublattice is negligibly small. The defect concentration is found to increase in an approximately linear relationship with an increase of the interface velocity or undercooling. Further there is no significant anisotropy in the defect concentrations for different interface orientations.

S1.00176 ABSTRACT WITHDRAWN —

S1.00177 Strain Engineering in Self-Assembled Vertically Aligned Nanocomposite Thin Films, ZHENXING BI, MPA-CINT, MS K771, Los Alamos National Laboratory, NM 87545, USA, AIPING CHEN, Texas A&M University, SOPHIE HARRINGTON, University of Cambridge, HAIYAN WANG, Texas A&M University, JUDITH DRISCOLL, University of Cambridge, QUANXI JIA, MPA-CINT, MS K771, Los Alamos National Laboratory — Self-assembled vertically aligned nanocomposite (VAN) thin films hold great promises in engineering material functionalities including ferroelectric, ferromagnetic, and multiferroics by tunable intrinsic strains. The VAN exhibits a well ordered vertically columnar structure with highly epitaxial quality in thin film. In this work, we describe the approach of strain tuning in $(\text{BiFeO}_3)_x:(\text{Sm}_2\text{O}_3)_{1-x}$, $(\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3)_{0.7}:(\text{Mn}_3\text{O}_4)_{0.3}$ and $(\text{BaTiO}_3)_x:(\text{Sm}_2\text{O}_3)_{1-x}$ VAN thin films grown by pulsed laser deposition (PLD). We investigate the intrinsic strain mechanism in VAN thin films as well as the effects of film growth kinetics and thermodynamic stability to the final VAN architecture. We also demonstrate the tunable “microstructure - strain - physical properties” relationships in VAN thin films. Experiment results reveal that: 1) Enhanced vertical strain can cause systematic reduction of dielectric loss of VAN thin films; 2) Strain tuning in ferromagnetic VAN thin films can lead to tunable T_c and magneto resistance; and 3) RT ferroelectric can be achieved by strain tuning of BTO and results the highest T_c in VAN thin film. Furthermore, geometrically controlled nanoporous structure can also be processed by thermal treatment on VAN thin films.

S1.00178 STM Examination of Trithiapentacene on Vicinal Gold (788), AMANDA BROWN, JEREMIAH VAN BAREN, University of New Hampshire, Department of Physics, JEREMY KINTIGH, University of New Hampshire, Department of Chemistry, JUN WANG, University of New Hampshire, Department of Physics, GLEN MILLER, University of New Hampshire, Department of Chemistry, KARSTEN POHL, University of New Hampshire, Department of Physics — Trithiapentacene (TTPO) is a member of a group of promising novel pentacene derivatives of interest in organic electronics for their excellent resistance to photooxidation and a range of band gaps. TTPO is a robust molecule with a HOMO-LUMO gap of 1.95 eV that can be thermally evaporated onto an electrode. TTPO is a polar species of pentacene with centered oxygen and sulfur bridge substituents. The vicinal gold (788) surface is a well studied surface on which pentacene molecules and other pentacene derivatives such as 6,13-dichloropentacene self assemble in long range order. We will present a STM study of TTPO on Au (788) addressing the possibility of self-assembly for organic semiconductor applications.

S1.00179 High resolution STM imaging of a unit cell of $\text{SrTiO}_3(100)-\sqrt{5} \times \sqrt{5} - R26.6^\circ$ surface superstructures, ICHIRO SHIRAKI, University of Yamanashi, KAZUSHI MIKI, National Institute for Materials Science (NIMS), SHUHENG PAN, University of Houston — $\text{SrTiO}_3(100)-\sqrt{5} \times \sqrt{5} - R26.6^\circ$ surfaces were studied by scanning tunneling microscope (STM) in ultra-high vacuum conditions at room temperatures. In the our previous report, we showed the arrangement of titanium and oxygen atoms in the unit cells of a $(\sqrt{5} \times \sqrt{5})$ surface superstructure with scanning tunneling microscope and concluded the TiO_2 layer is the terminating plane of the $(\sqrt{5} \times \sqrt{5})$ surface [1]. Recently, we succeeded in imaging the surfaces in filled states with much higher spatial resolution. Oxygen atomic orbitals are individually recognized and the local structures at the center of the O fourfold hollow site with $(\sqrt{5} \times \sqrt{5})$ periodicity are more clearly seen. Comparing our experimental results with the previous works, especially a theoretical study of O-vacancy model [2] and an experimental and theoretical study of Sr adatom model [3], detailed discussion on $\sqrt{5} \times \sqrt{5}$ surfaces became possible.

S1.00180 Real-Time Grazing Incidence Small Angle X-Ray Scattering Studies of the Growth Kinetics of Sputter-Deposited Silicon Thin Films, ALEXANDER DEMASI, Department of Physics, Boston University, Boston MA, GOZDE ERDEM, Division of Materials Science and Engineering, Boston University, Boston MA, PRIYA CHINTA, Department of Physics, University of Vermont, Burlington VT, RANDALL HEADRICK, Department of Physics and Materials Science Program, University of Vermont, Burlington VT, KARL LUDWIG, Department of Physics, Boston University, Boston MA — The fundamental kinetics of thin film growth remains an active area of investigation. In this study, silicon thin films were grown at room temperature on silicon substrates via both on-axis and off-axis plasma sputter deposition, while the evolution of surface morphology was measured in real time with *in-situ* grazing incidence small angle x-ray scattering (GISAXS) at the National Synchrotron Light Source. GISAXS is a surface-sensitive, non-destructive technique, and is therefore ideally suited to a study of this nature. In addition to investigating the effect of on-axis versus off-axis bombardment, the effect of sputter gas partial pressure was examined. *Post-facto*, *ex-situ* atomic force microscopy (AFM) was used to measure the final surface morphology of the films, which could subsequently be compared with the surface morphology determined by GISAXS. Comparisons are made between the observed surface evolution during growth and theoretical predictions. This work was supported by the Department of Energy, Office of Basic Energy Sciences.

S1.00181 Structure of electrolyte decomposition products on high voltage spinel cathode materials determined by in situ neutron reflectometry, JIM BROWNING, GABRIEL VEITH, LOIC BAGGETTO, NANCY DUDNEY, WYATT TENHAEFF, Oak Ridge National Laboratory — Interfacial reactions on electrical energy storage (EES) materials mediate their stability, durability, and cycleability. Understanding these reactions in situ is difficult since they occur at the liquid-solid interface of an optically absorbing material that hinders the use of techniques such as infra-red spectroscopy. Furthermore, since the interfaces involve liquids classic vacuum-based analytical methods can only probe reaction products, which are stable under vacuum. Here, we present the results of an in situ neutron reflectometry study detailing the formation of a thick solid-electrolyte interphase (SEI) on a high voltage spinel cathode material. The cathode/electrolyte system used in this study is a $\text{LiMn}_{1.5}\text{Ni}_{0.5}\text{O}_4$ thin film subjected to a 1.2 molar LiPF_6 in 1:1 ethylene carbonate - dimethyl carbonate electrolyte solution.

S1.00182 Dependence of optical absorption of thin nanocomposite films on inclusions distribution, IRINA BARIAKHARTAR, Boston College, VALERI LOZOVSKI, OLGA OBRAZUMOVA, GALINA STRILCHUK, KNU, Ukraine — It is well known, that one of the ways to widen the spectral range of the elements of photovoltaic systems is using the nanocomposite films as part of its active element. The problem of characterization of the optical properties of nanocomposite thin films, especially with inhomogeneous distribution of inclusions, arises. In this work, we propose an approach which allows us to determine the parameters of the nanocomposite film which cannot be measured directly. The approach is based on the previous works where the ultrathin films electrostatics was studied earlier. The absorption spectrum sensibly depends on the film parameters. They are the inclusions' concentration in the film, the presence of a shell of the inclusion particles and the size of this shell, the spatial orientation of particles in a layer and the presence of different types of particles and their relative spatial distribution in the film. The strong dependence of the absorption profiles on the type of distribution of particles along the film, *ceteris paribus*, is demonstrated in this report.

S1.00183 Precise Control of Areal Density of 'Click' Functional Groups on Nanoparticle Surfaces, YANIR MAIDENBERG, JEFFREY KOBERSTEIN, Columbia University — Tremendous effort has been invested into devising methods that enable full control of surface functionalities by use of a mixture of two self-assembled monolayers (SAM). By assuming control of the relative amounts of SAM moieties on a surface it is possible to fabricate materials with well-known molecular compositions and, thus, well-characterized properties. This could be achieved by mixing one reactive and another inert modifying agent or by utilizing two agents with complementary properties. These surfaces have shown benefits in various applications ranging from sensing to DNA sequencing. Two methods are performed to control the exact amount of 'click' functionalities on the curved surfaces of silica and iron oxide. The density of alkyne is controlled by mixing two silanes, of which one bears the alkyne functionality, and the other does not. Azide density, however, is controlled in a novel method using the kinetic control of the substitution reaction of bromide to azide on a bromide-terminated silanized surface. We report herein a novel method to quantitatively ascertain no phase separation of the silanes occurred on the curved surface, and that true mixing was achieved. We also show that true mixing of silanes occurs regardless of surface geometry or identity for both systems

S1.00184 First-principles study of adsorption and dissociation of CO₂ on α -Pu (020) surface¹, JIANGUANG WANG, ASOK K. RAY, Department of Physics, University of Texas at Arlington, Arlington, Texas 76019, USA — The adsorption and dissociation of CO₂ on the α -Pu (020) surface has been investigated using density functional theory (DFT) within generalized gradient approximation (GGA). The full-potential FP/LAPW+lo method has been used to calculate the adsorption energies at the scalar relativistic with no spin-orbit coupling (NSOC) and fully relativistic with spin-orbit coupling (SOC) theoretical levels. The completely dissociated configurations (C+O+O) exhibit the strongest binding with the surface, followed by the partially dissociated configurations (CO+O), with the molecular CO₂ adsorption having the weakest binding with the Pu surface. It is found that the SOC effect increases the adsorption energies for all considered adsorptions. For all initial vertically upright orientations, the geometry and orientation of the CO₂ molecule do not change after optimization. For all initial flat lying orientations, the final state of the CO₂ molecule corresponds to a bent geometry with a bond angle of $\sim 130^\circ$. For CO+O co-adsorption, the stable configurations corresponded to CO dipole moment orientations of $105^\circ - 167^\circ$ with respect to the normal surface. The local density of states and difference charge densities are also discussed.

¹This work is partially supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525) and by the Department of Energy.

S1.00185 GENERAL THEORY/COMPUTATIONAL PHYSICS —

S1.00186 Calculating thermodynamics properties of quantum systems by a non-Markovian Monte Carlo procedure¹, YANIER CRESPO HERNANDEZ, International Centre for Theoretical Physics (ICTP), ALESSANDRO LAIO, GIUSEPPE SANTORO, ERIO TOSATTI, Scuola Internazionale Superiore di Studi Avanzati (SISSA), CONDENSED MATTER TEAM — We present a history-dependent Monte Carlo scheme for the efficient calculation of the free energy of quantum systems inspired by Wang-Landau and metadynamics. In the two-dimensional quantum Ising model, chosen here for illustration, the accuracy of free energy, critical temperature, and specific heat is demonstrated as a function of simulation time and successfully compared with the best available approaches. The approach is based on a path integral formulation of the quantum problem and can be applied without modifications to quantum Hamiltonians of any level of complexity. The combination of high accuracy and performance with a much broader applicability is a major advance with respect to other available methods.

¹Supported by a MIUR/PRIN contract and benefited from the environment provided by the CNR/ESF/EUROCORES/FANAS/AFRI project.

S1.00187 Application of Group Representation Theory to Derive Hermite Interpolation Polynomials on a Triangle¹, P.G. KASSEBAUM, C.R. BOUCHER, L.R. RAM-MOHAN, Worcester Polytechnic Institute — Current methods used to devise sets of Hermite interpolation polynomials of minimal order that ensure $C^{(n)}$ continuity across triangular element boundaries in two dimensions are not readily extensible to higher dimensions. The extension of such methods is especially difficult when the number of degrees of freedom afforded by data at points is different from the number of degrees of freedom determined by the coefficients of a complete polynomial basis to a particular order. This work introduces a formalism based on group representation theory that can accomplish this task in general. The method is introduced through the derivation of $C^{(1)}$ continuous Hermite polynomials that interpolate data at the three vertices of an equilateral triangular element. These interpolation polynomials are reported here for the first time. The polynomials derived here are compared to the standard polynomials defined in a right triangle by using the two sets of polynomials to solve the Laplace equation over finite elements, and also by interpolating example functions over a single triangle element.

S1.00188 Finite Temperature Properties of Clusters by Replica Exchange Metadynamics: The Water Nonamer, YINGTENG ZHAI, Key Laboratory for Computational Physical Sciences (MOE) and Surface Physics, Fudan University, Shanghai 200433, China, ALESSANDRO LAIO, ERIO TOSATTI, International School for Advanced Studies (SISSA), via Bonomea 265, 34136 Trieste, Italy, XINGAO GONG, Key Laboratory for Computational Physical Sciences (MOE) and Surface Physics, Fudan University, Shanghai 200433, China — We introduce an approach for the accurate calculation of thermal properties of classical nanoclusters. Based on a recently developed enhanced sampling technique, replica exchange metadynamics, the method yields the true free energy of each relevant cluster structure, directly sampling its basin and measuring its occupancy in full equilibrium. All entropy sources, whether vibrational, rotational anharmonic and especially configurational – the latter often forgotten in many cluster studies – are automatically included. For the present demonstration we choose the water nonamer (H₂O)₉, an extremely simple cluster which nonetheless displays a sufficient complexity and interesting physics in its relevant structure spectrum. Within a standard TIP4P potential description of water, we find that the nonamer second relevant structure possesses a higher configurational entropy than the first, so that the two free energies surprisingly cross for increasing temperature.

S1.00189 The predictive integration method for dynamics of infrequent events, EKIN CUBUK, AMOS WATERLAND, EFTHIMIOS KAXIRAS, Harvard University — With the increasing prominence and availability of multi-processor computers, recasting problems in a form amenable to parallel solution is becoming a critical step in effective scientific computation. We present a method for parallelizing molecular dynamics simulations in time scale, by using predictive integration. Our method is closely related to Voter's parallel replica method, but goes beyond that approach in that it involves speculatively initializing processors in more than one basin. Our predictive integration method requires predicting possible future configurations while it does not suffer from restrictions due to correlation time after transitions between basins.

S1.00190 Coarse graining approach to First principles modeling of radiation cascade in large Fe super-cells, KHORGOLKHUU ODBADRAKH, DON NICHOLSON, AURELIAN RUSANU, Oak Ridge National Laboratory, YANG WANG, Pittsburgh Supercomputing Center, ROGER STOLLER, XIAO GUANG ZHANG, GEORGE STOCKS, Oak Ridge National Laboratory — First principles techniques employed to understand systems at an atomistic level are not practical for large systems consisting of millions of atoms. We present an efficient coarse graining approach to bridge the first principles calculations of local electronic properties to classical Molecular Dynamics (MD) simulations of large structures. Local atomic magnetic moments in crystalline Fe are perturbed by radiation generated defects. The effects are most pronounced near the defect core and decay with distance. We develop a coarse grained technique based on the Locally Self-consistent Multiple Scattering (LSMS) method that exploits the near-sightedness of the electron Green function. The atomic positions were determined by MD with an embedded atom force field. The local moments in the neighborhood of the defect cores are calculated with first-principles based on full local structure information. Atoms in the rest of the system are modeled by representative atoms with approximated properties. This work was supported by the Center for Defect Physics, an Energy Frontier Research Center funded by the US Department of Energy, Office of Science, Office of Basic Energy Sciences.

S1.00191 Modeling Nonlinear Non-Stationary Self-Organized Asymptotic States in High Energy Density Plasmas Driven by Intense Crossing Laser Beams¹, BEDROS AFEYAN, Polymath Research Inc., Pleasanton, CA — The multiscale dynamics of Vlasov-Maxwell and Vlasov-Poisson systems where non-stationary self-organized states can be formed is a grand challenge. From chaotic particle orbits there arise collective self-consistent fields which are highly coherent. We will explain the novel aspects of these states and contrast them with electron plasma waves which are small amplitude disturbances that are naturally resonant. We will also point out connections between these systems and the high Reynolds number limit of 2D incompressible (Euler) turbulence, galaxy formation models and applications in the nonlinear optics of laser-matter interactions. Techniques will be given of capturing the multiscale dynamics and the conformal invariance hypothesis in the fine scale structures beneath the large scale order found in such systems.

¹Work supported by a grant from the DOE NNSA SSAA program

S1.00192 Multiscale modeling of nanofoams under irradiation¹, E.M. BRINGA, CONICET & Instituto de Ciencias Basicas, Universidad Nacional de Cuyo, Argentina, J. RODRIGUEZ-NIEVA, Instituto Balseiro, Universidad Nacional de Cuyo, Argentina, J.D. MONK, Cain Department of Chemical Engineering, Louisiana State University, J.A. CARO, Los Alamos National Laboratory, M.J. LOEFFLER, NASA Goddard Space Flight Center, Astrochemistry Branch, Code 691, T.A. CASSIDY, CalTech/JPL, R.E. JOHNSON, R.A. BARAGIOLA, Laboratory for Atomic and Surface Physics, University of Virginia, D. FARKAS, Department of Materials Sciences, Virginia Tech — Nanoscale porosity appears in solids under a number of conditions: radiation damage in nuclear reactors, initial stages of ductile failure, in astro-materials, etc. Using molecular dynamics (MD) simulations, we analyze the radiation damage and surface modification of materials with various nanoscale porosities, where experimental techniques can be difficult to use and interpret. We consider (a) irradiation with ions with energies in the range 1-25 keV, of interest for fusion and fission energy applications; (b) swift heavy ion irradiation, with energies up to few GeV, relevant for track formation and interstellar grain evolution. We find that irradiation effects have larger spatial extent than for full-density solids and include the production of point-defects and twins which change the mechanical properties of the samples. We use our MD results as input for a Monte Carlo (MC) code to calculate sputtering yields from nanofoams of different geometries under different irradiation conditions. We also use our MD results to build models which predict possible radiation endurance under intense irradiation.

¹E.M. Bringa thanks support from PICT2009-0092

S1.00193 Application of Gaussian Approximation Potentials to Barium Titanate, JASON VIELMA, GUENTER SCHNEIDER, Oregon State University — The computational study of complex phenomena over long time and distance scales not accessible to first principles calculations requires empirical potentials usually derived by integrating out the electronic degree of freedoms. Recently, a parameter free approach called Gaussian Approximation Potentials (GAP) has been shown that it can duplicate first principles density functional theory (DFT) total energies and atomic forces accurately [1]. In a GAP the atomic neighborhood of an atom is projected onto the angular momentum channels of Wigner-D functions, yielding a bispectrum of the expansion coefficients of the atomic density. A non-parametric Gaussian Process regression is used to fit a database of total energies and forces to the combination of angular momentum channels constituting the bispectrum. We report initial results of using a GAP to describe the ferroelectric perovskite Barium Titanate (BaTiO_3).

S1.00194 Ab initio simulation of radiation damage in nuclear reactor pressure vessel materials, DANIEL WATTS, DANIEL FINKENSTADT, U.S. Naval Academy — Using Kinetic Monte Carlo we developed a code to study point defect hopping in BCC metallic alloys using energetics and attempt frequencies calculated using VASP, an electronic structure software package. Our code provides a way of simulating the effects of neutron radiation on potential reactor materials. Specifically we will compare the Molybdenum-Chromium alloy system to steel alloys for use in nuclear reactor pressure vessels.

S1.00195 Influence of Nutation of the Projectile on Fracture of the Anisotropic Target, ANDREY RADCHENKO, Tomsk State University of Architecture and Building, Russia, PAVEL RADCHENKO, Institute of Strength Physics and Materials Science SB RAS, Russia — In actual practice the direction of the vector of velocity, as a rule, doesn't coincide with the direction of a longitudinal axis of a moving body, and makes with it some angle named the angle of nutation. The nutation influence on process of interaction of the projectile and a target is defined not only by its size, but also geometrical and kinematic parameters of the process. It is obvious that for a case of the prolonged projectile the angle of nutation influence is more considerable, than for the compact projectile because in this case the nutation angle presence changes not only a picture of strain-stress state of interaction bodies, but also leads to loss of stability in the projectile. The three-dimensional problem of oblique high-velocity interaction of the prolonged cylindrical projectile from steel with an anisotropic target from organoplastic is considered. Lengthening of the projectile makes from 15 to 30 calibers, the range of initial velocities of the projectile from 700 to 3000 m/sec is researched. Modeling is carried out numerically by a method of finite elements. Influence of nutation angle and rotation of the projectile on fracture of target and stability of the projectile is analyzed.

S1.00196 Mechanical Behavior of Ceramic Composites under Pulse Loadings¹, EVGENIYA SKRIPNYAK, VLADIMIR A. SKRIPNYAK, VLADIMIR V. SKRIPNYAK, National Research Tomsk State University, TOMSK STATE UNIVERSITY TEAM — The prediction of mechanical behavior ceramic composites under pulse loadings is the complicated problem owing to insufficient knowledge about laws of structure evolution and nucleation and accumulation of damages. Computer simulation of mechanical behavior of ceramic composites at single and repeated pulse influences of submicrosecond duration are presented in the given work. The model of the structured representative volume of ultrafine-grained ceramics composites was developed using the data of microscopic researches. Deformation and damage of structured representative volumes of some ceramic composites on meso-scale level were simulated under pulse loadings having amplitudes near several GPa. The critical fracture stress on meso-scale level depends not only on relative volumes of voids and strengthened phases, but also sizes of corresponding structure elements. It was shown that the isolated micro- and meso-scale cracks can be generated in ceramic composites at pulse amplitude less than the Hugoniot elastic limit. In the studied ceramic composites the critical failure stress in spall zone is changed nonmonotonically with growth of the volume concentration of strengthened phases.

S1.00197 Interaction of free boundary of fluid layer with Taylor wave created by laser pulse, ALEXEY SYUNDYUKOV, MIPT, MICHAEL ASTASHKIN, VICTOR BARANOV, ALLA GEORGIEVSKAYA, ANATOLY GOLUBINSKY, RFNC-VNIIEF, EVGENIY MESHKOV, SarFTI NRNU MEPhI, DMITRIY IRINICHEV, VITALIY KHATUNKIN, RFNC-VNIIEF — In the hydrodynamic laboratory of SarFTI NRNU MEPhI experiments carry out to study the instability of the free surface of a thin (about 2 mm) layer of fluid, developing after the going to surface nonsteady decaying shock wave (Taylor wave) with amplitude of about 1 kbar. The Taylor wave was produced by evaporating a thin (about 1 mm) target located on the surface layer under the influence of the laser pulse duration of 10 ns. The results of the experiments and discussion are presented.

S1.00198 Superconductivity and Magnetism in isovalent substituted Europium Iron-Arsenide Superconductor $\text{EuFe}_2\text{As}_{2-x}\text{P}_x$, TAKUYA ISHIKAWA, YOHEI JONO, KASUMI TASHIMA, KAZUO KADOWAKI, TAKANARI KASHIWAGI, University of Tsukuba — The $\text{EuFe}_2\text{As}_{2-x}\text{P}_x$ system is known as a coexisting system of superconductivity and magnetism with varying isovalent substitution concentration of P in place of As. Magnetism seems to originate from localized Eu^{2+} moments around 19 K, whereas Superconductivity occurs at 28 K in $x = 0.4$. We have studied magnetic and transport properties in various single crystals grown by the self-flux method in a vertical Bridgman furnace, whose compositions are characterized by EPMA and ICP-AES. From temperature dependence of magnetic susceptibility Eu has a magnetic moment of $7.9\mu_B$ indicating Eu^{2+} obtained previously, and did not depend on x upto $x = 0.3$, then coexists with superconductivity above $x = 0.4$. At the coexisting region we showed a reentrant behavior of the superconductivity in resistivity and it shows a peculiar magnetic field dependence. We show the precise phase diagram and superconductivity as a function of x .

S1.00199 Four Types of Single-Walled SiGe Nanotubes: Existence and Stability¹, PRABATH WANAGURU, ASOK K. RAY, The University of Texas at Arlington — Four types of SiGe armchair nanotubes from (3, 3) to (12, 12) have been studied using the cluster approximation and the dangling bonds saturated by H atoms. The tubes have been spin- and geometry optimized using the hybrid functional B3LYP, the all electron 6-31G**//3-21G* basis set and the GAUSSIAN 03/09 suite of software. Cohesive energies, band gaps, bond lengths, hybridization of Ge and Si atoms, among others will be presented in details. In general, cohesive energy of type I tubes decrease and saturate around 3.389eV and that of, type IV tubes increase and saturate around 3.411eV. The cohesive energy of both type II and type III tubes indicates oscillatory behavior eventually reaching saturation as the tube diameter increases. Band gaps, in general for all four types decrease as the tube diameter increases. The band gap of type I tubes saturate at around 1.0eV and type IV tubes indicate the lowest saturation gap of about 0.3eV. While most types I-III tubes show sp^2 or a mixture of sp^2 and sp^3 bonding, some type IV tubes show predominantly p bonding. Results of types I-III will be compared with previous results using the cluster approximation and the B3LYP/LANL2DZ level of theory.²

S1.00200 Rational computational design of high energy density capacitor dielectrics through navigation of the polymer chemical space¹, GHANSHYAM PILANIA, CHENCHEN WANG, CHUN-SHENG LIU, R. RAMPRASAD, University of Connecticut — Next generation capacitor dielectrics should provide an attractive combination of high dielectric constant, fast response, low dielectric loss, high breakdown field and high temperature stability. With these objectives in mind, we adopt a research strategy in which newly developed high throughput first principles computational techniques are used to rapidly, and accurately, navigate the polymer chemical space to identify promising candidates. After validating our high throughput approach against computationally expensive dispersion corrected density functional theory calculations, we systematically study a number of C, Si and Ge backbone containing polymers with various side chain functional groups. Our initial accomplishment is the identification of new class of polymer systems with a large dielectric constant, and band gap large enough to provide reasonable insulating properties. These predictions are currently being validated by parallel experimental work, and are being further refined.

¹This research is based upon work supported by the Office of Naval Research. Computational support was provided through a National Science Foundation Teragrid Resource Allocation.

S1.00201 Constraint density functional calculations for multiplets in ligand-fields: Applications to Fe-phthalocyanine and $\text{Al}_2\text{O}_3:\text{Cr}^{3+}$, Y. KITAOKA, K. NAKAMURA, T. AKIYAMA, T. ITO, Mie University, M. WEINERT, University of Wisconsin-Milwaukee, A.J. FREEMAN, Northwestern University — In transition-metal-based complexes and molecules, multiplet structures are essential in understanding the electronic structure. However, it is often difficult to evaluate a *true* ground state or the *lowest* state within a given ligand (or crystal) symmetry from first principles calculations based on density-functional theory (DFT). Here, we propose a simple DFT approach, implemented into the FLAPW method², to treat multiplets in ligand-fields, by imposing a density matrix constraint on the *d*-orbital occupation numbers. We demonstrate the utility of this approach for the case of an isolated single Fe phthalocyanine (FePc) and a Cr impurity in a corundum Al_2O_3 . For the FePc, results predict that there are three stationary states of ^3E_g , $^3B_2$, and $^3A_2$ in the Fe^{2+} ion, and our total energy calculations clearly demonstrate that the ground state is $^3A_{2g}$. In the case of the $\text{Al}_2\text{O}_3:\text{Cr}^{3+}$, where an on-site Coulomb correlation correction ($+U$) is incorporated, the ground state is $^4A_2$ and the total energy difference between the ground state and the excited state $^4T_2$, 2.9 eV, roughly agrees with an experimental value of 2.23 eV.

S1.00202 The effects of micro-alloying elements on a BCC iron grain boundaries, SUNGHO KIM, SEONG-GON KIM, HONGJOO RHEE, MARK HORSTEMEYER, Mississippi State University — The effects of micro-alloying elements, vanadium and niobium, on a few of BCC Fe grain boundaries are studied using Density Functional Theory calculations to develop an advanced high-strength steel alloy material. The lowest energy configuration of the grain boundaries structures are obtained from the first-principles calculations. The substitutional and interstitial point defect formation energies of micro-alloying elements in the grain boundaries are compared. The segregation energies of micro-alloying elements onto the grain boundaries and its fractured surfaces are computed. The cohesive energy calculations of the grain boundaries with and without micro-alloying elements are performed to investigate the effects of micro-alloying elements on the cohesive strength of the grain boundaries. The tensile and shear tests on the grain boundaries with and without the segregants are carried out to study the effect on the grain boundaries.

S1.00203 Diamond-like carbon-metal nanocomposites for solar thermal energy, GEORGIOS TRITSARIS, EFTHIMIOS KAXIRAS, Harvard University, KAXIRAS RESEARCH GROUP TEAM — Solar thermal energy systems are a possible technology for clean energy production. Carbon-based materials, including diamond-like carbon (DLC), have been suggested as promising for solar energy harvesting [1]. A strategy for tuning the properties of DLC is the incorporation of transition metal nanoparticles in the material [2]. Using density functional theory calculations, we study the structural, mechanical, and optical properties of DLC with transition metal nanoinclusions such as silver and copper. Key properties of the nanocomposites, such as the sp^2/sp^3 bonding ratio, elastic properties, and optical band gaps are reported. Such carbon-metal alloys are calculated to show enhanced performance over DLC.

S1.00205 The effects of 5-7 defects on the mechanical characteristics of carbon nanotubes intramolecular junctions and their influences on electronic properties, WEN-JAY LEE, JEE-GONG CHANG, YENG-TSENG WANG, WAN-SHENG SU, National Center for High-Performance Computing, Tainan 741 — This study utilizes molecular dynamics simulations and first-principles techniques to investigate mechanical and electronic properties of the single-walled carbon nanotube (SWCNT) intramolecular junctions (IMJs). Results show that the mechanical behaviors are mainly affected by the diameter of thinner segment of two composed tubes, whereas are barely able to be influenced by the number of 5-7 defects in the interface region. With applied compression, the yielding stress and Young's modulus of the SWCNT IMJs are found to be strongly associated with the orientation of two contacted heptagon rings where their ordering values are vertical > tilted > parallel to the axial direction. Under applied tensile, a lowest value in the yielding stress and Young's modulus is found on the parallel status, but the other two reveal alternating relations. Moreover, the magnitude of the stress amplitude is proportional to the Young's modulus and yielding stress and the buckling location is shown to be dependence on different orientations of two contacted heptagon rings. Finally, our first-principles calculations indicated that the considered SWCNT (5,0)/(8,0) IMJs at a certain length with different distributions of 5-7 defects on the tube wall exhibit diverse electronic properties, such as the changes of the density of states and modulation of energy gap. With increasing length, the numbers of states near the Fermi level region increase significantly and the energy gap tends to shrink as well.

S1.00206 Optical absorption in degenerately doped semiconductors: Mott transition or Mahan excitons?, ANDRÉ SCHLEIFE, Lawrence Livermore National Laboratory, CLAUDIA RÖDL, KARSTEN HANNEWALD, FRIEDHELM BECHSTEDT, Institut fuer Festkoerpertheorie und -optik, Friedrich-Schiller-Universitaet Jena — In the exploration of material properties, parameter-free calculations are a modern, sophisticated complement to cutting-edge experimental techniques. *Ab-initio* calculations are now capable of providing a deep understanding of the interesting physics underlying the electronic structure and optical absorption, e.g., of the transparent conductive oxides. Due to electron doping, these materials are conductive even though they have wide fundamental band gaps. The degenerate electron gas in the lowest conduction-band states drastically modifies the Coulomb interaction between the electrons and, hence, the optical properties close to the absorption edge. We describe these effects by developing an *ab-initio* technique which captures also the Pauli blocking and the Fermi-edge singularity at the optical absorption onset, that occur in addition to quasiparticle and excitonic effects. We answer the question whether free carriers induce an excitonic Mott transition or trigger the evolution of Wannier-Mott excitons into Mahan excitons. The prototypical *n*-type zinc oxide is studied as an example.

S1.00207 Fast and Accurate Modeling of Molecular Energies with Machine Learning, ANATOLE VON LILIENFELD, Argonne National Laboratory, MATTHIAS RUPP, Technical University Berlin, ALEXANDRE TKATCHENKO, Fritz-Haber Institute Berlin, KLAUS-ROBERT MUELLER, Technical University Berlin — A machine learning model for the prediction of atomization energies of a diverse set of organic molecules, based on nuclear charges and atomic positions only, will be discussed. The problem of obtaining molecular energies across chemical compound space, aka. as solving Schrodinger's equation, is mapped onto a non-linear statistical regression problem of reduced complexity. We use eigenvalues of a "Coulomb"-matrix to encode all Cartesian and atomic number variables of a molecule. Regression models are trained on, and compared to, atomization energies computed with hybrid density-functional theory for a sub-set of the GDB-13 database consisting of more than seven thousand molecules. Cross-validation yields a mean absolute error of less roughly 10 kcal/mol. Applicability and transferability is demonstrated for the prediction of potential energy curves of unseen molecules.

S1.00208 Development of a relativistic impurity embedding code based on the KKR Green function method, DAVID BAUER, PASCAL KORDT, PHIVOS MAVROPOULOS, RUDOLF ZELLER, STEFAN BLÜGEL, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — We present a new implementation of the KKR Green function method for electronic structure calculations of impurity atoms embedded in a crystalline host. Our code is able to treat impurity atoms not necessarily positioned at host sites. This became possible by a two step approach: For large deviations of the impurity from the host position a virtual atom method is used where the host Green function is expanded around the new impurity position. Then, small displacements are treated by an expansion of the Green function. In addition, we include in our code a newly developed accurate method to directly solve the coupled Lippmann-Schwinger equations for non-spherical potentials via a system of algebraic equations. When spin-orbit effects are included in the presence of spin polarization, this is especially important for the irregular solutions because of the coupling of different angular momenta up to the origin. We apply the method to solve the Schrödinger, the scalar-relativistic as well as the Dirac equation by using appropriate source terms.

S1.00209 A constraint method for variational total energy calculations of electronic excitations within the Kohn-Sham scheme¹, BABAK SADIGH, Lawrence Livermore National Laboratory — We propose a general constraint on the occupations of single-particle orbitals within (hybrid) density-functional theory that allows a variational total energy formulation for extended systems containing arbitrary electronic excitations. This method is simple to implement and is ideal for studying structural relaxations and molecular-dynamics simulations in the presence of excitations since accurate forces can be calculated via the Hellman-Feynman theorem.

S1.00210 Quantum phase transitions of 2-d dimerized spin-1/2 Heisenberg models with spatial anisotropy , MING-TSO KAO, DENG-RUEI TAN, FU-JIUN JIANG, National Taiwan Normal University, FU-JIUN JIANG TEAM — Motivated by the unexpected Monte Carlo results as well as the theoretical proposal of a large correction to scaling regarding the critical theory for the staggered-dimer spin-1/2 Heisenberg model on the square lattice, we study the phase transitions induced by dimerization of several dimerized quantum Heisenberg models with spatial anisotropy using first principles Monte Carlo method. We focus on investigating the finite-size scaling of the observables $\rho_{s1}2L$ and $\rho_{s2}2L$ since such strategy might reveal the subtlety of determining the corresponding critical theory as suggest in [1]. Here ρ_{si} with $i \in \{1, 2\}$ and L refer to the spin stiffness in the i -direction and the spatial box size, respectively. Surprisingly, similar to the results found in [1], while we do observe a large correction to scaling for $\rho_{s1}2L$ of the staggered-dimer model on the honeycomb lattice, the observable $\rho_{s2}2L$ of the same model receives a negligible correction to its scaling. Further, our simulation data for all the models considered here including the herringbone- and ladder-dimer models are compatible with the established numerical values for $\nu, \beta/\nu$ and ω in the $O(3)$ universality class. To explain the results presented in this study, a deepened theoretical understanding for the critical theories of the models considered here is required.

S1.00211 Local-TQO and Stability of Frustration-Free Hamiltonians , JUSTYNA PYTEL, Oregon State University, SPYRIDON MICHALAKIS, California Institute of Technology — The attention of the condensed matter and mathematical physics communities has recently focused on Hamiltonians with low-energy sectors exhibiting some form of topological order. In our work [1], we present a generalization of the result of Bravyi et al. [2,3] on the stability of topological quantum order for Hamiltonians composed of commuting projections with a common zero-energy subspace. In particular, the commutativity condition can be removed: We prove stability of the spectral gap for gapped, frustration-free Hamiltonians under general, quasi-local perturbations. Also, we will discuss the “Local Topological Quantum Order” and “Local-Gap” conditions sufficient for proving stability.

S1.00212 New limits on violations of the equivalence principle from solar system observations , JACK MITCHAM, JAMES OVERDUIN, Towson University — The equivalence principle is the foundation of general relativity theory, but violations of this principle are generically predicted by theories that attempt to unify gravity with the other fundamental interactions of nature. Violations of equivalence could lead to measurable deviations of solar system bodies from their expected positions near stable or semi-stable Lagrange points. We extend earlier constraints using new observational data on Trojan and artificial satellites near Jupiter, Neptune, Mars and Earth.

S1.00213 Is Dark Energy Composed of Photons with Negative Mass (Dark Photons)? , DOUGLAS SNYDER, None — Dark energy may be composed of photons with negative inertial and gravitational mass. Since the photons comprising dark energy would have negative mass, they could not be observed even though they exert a repulsive gravitational force on photons that have positive mass. Furthermore, dark photons possess little mass which is a feature of dark energy. Dark photons are small enough to comprise the needed density to support a universe that is close to flat. They also may allow for repelling entities with positive mass while they are attracted to particles with positive mass, a possible requirement of dark energy. First presented at Space Telescope Science Institute Spring Symposium: A Decade of Dark Energy, May 5-8, 2008, Baltimore, MD.

S1.00214 Visualization and Analysis of Synthetic Observations of Star Forming Regions , MICHELLE BORKIN, Harvard University, CHRISTOPHER BEAUMONT, Institute for Astronomy, University of Hawaii, THOMAS ROBITAILLE, Max Planck Institute for Astronomy, STELLA OFFNER, ALYSSA GOODMAN, Harvard-Smithsonian Center for Astrophysics — We present multidimensional visualizations used for the exploration, analysis, and comparison of simulated synthetic observations and real astronomical observational data cubes. By comparing synthetic observations of simulated star forming regions to real observational radio data cubes utilizing 2D and 3D visualization techniques we are able to more effectively and efficiently compare these types of data, in particular their hierarchical structure and kinematic features such as outflows or expanding shells. For our synthetic data we use simulations performed with the ORION adaptive mesh refinement (AMR) three-dimensional gravito-radiation-hydrodynamics code which follow the collapse and evolution of protostars down to AU size scales. The synthetic observations are produced using MOLLIE, a molecular line radiative transfer code. Through comparisons of 2D dendrogram representations of the star forming region’s hierarchical structure, 2D column maps, and 3D data visualizations we are able to gain a better understanding of the physical structures and kinematic features, and enhance the interpretation of astronomical data cubes.

S1.00215 Implementation of cryptographic hash function SHA256 in C++ , AKASH SHRIVASTAVA, Manipal Institute of Technology, Udipi, Karnataka, India — This abstract explains the implementation of SHA Secure hash algorithm 256 using C++. The SHA-2 is a strong hashing algorithm used in almost all kinds of security applications. The algorithm consists of 2 phases: Preprocessing and hash computation. Preprocessing involves padding a message, parsing the padded message into m-bits blocks, and setting initialization values to be used in the hash computation. It generates a message schedule from padded message and uses that schedule, along with functions, constants, and word operations to iteratively generate a series of hash values. The final hash value generated by the computation is used to determine the message digest. SHA-2 includes a significant number of changes from its predecessor, SHA-1. SHA-2 consists of a set of four hash functions with digests that are 224, 256, 384 or 512 bits. The algorithm outputs a 256 bits message block with an internal state block of 256 bits and initial block size of 512 bits. Maximum message length in bit is generated is $2^{64}-1$, over all computed over a series of 64 rounds consisting of several operations such as and, or, Xor, Shr, Rot. The code will provide clear understanding of the hash algorithm and generates hash values to retrieve message digest.

S1.00216 HIGH PRESSURE PHYSICS —

S1.00217 Pressure-Induced Structural, Magnetic and Transport Transitions in the Two-Legged Ladder $\text{Sr}_3\text{Fe}_2\text{O}_5$, TAKAFUMI YAMAMOTO, CEDRIC TASSEL, YOJI KOBAYASHI, Kyoto University, TAKATERU KAWAKAMI, Nihon University, TAKU OKADA, TAKÉHIKO YAGI, University of Tokyo, HIDE TO YOSHIDA, TAKANORI KAMATANI, YOSHITAKA WATANABE, Nihon University, TAKUMI KIKEGAWA, High Energy Acceleration Research Organization (KEK), MIKIO TAKANO, KAZUYOSHI YOSHIMURA, HIROSHI KAGEYAMA, Kyoto University — The layered compound SrFeO_2 with an FeO_4 square-planar motif exhibits an unprecedented pressure-induced spin state transition ($S = 2$ to 1), together with an insulator-to-metal (I-M) and an antiferromagnetic-to-ferromagnetic (AFM-FM) transition. In this study, we have studied the pressure effect on the structural, magnetic and transport properties of the structurally related two-legged spin ladder $\text{Sr}_3\text{Fe}_2\text{O}_5$. When pressure was applied, this material first exhibited a structural transition from $Immm$ to $Ammm$ at $P_s = 30 \pm 2$ GPa. This transition involves a phase shift of the ladder blocks from $(1/2, 1/2, 1/2)$ to $(0, 1/2, 1/2)$, by which a rock-salt type SrO block with a seven-fold coordination around Sr changes into a CsCl -type block with eight-fold coordination, allowing a significant reduction of volume. However, the $S = 2$ antiferromagnetic state stays the same. Next, a spin state transition from $S = 2$ to $S = 1$, along with an AFM-FM transition was observed at $P_c = 34 \pm 2$ GPa, similar to that of SrFeO_2 . A sign of an I-M transition was also observed at pressure around P_c .

S1.00218 Uncover the nature of cubic-rhombohedral transition in Fe_{1-x}O, QINGYANG HU, George Mason University, YANG DING, HPSynC, Carnegie Institute Washington, HONGWEI SHENG, George Mason University — Transition metal monoxide Fe_{1-x}O is an archetypal Mott insulator and an important geological compound. Despite considerable study during the past few decades, the origin of the high-pressure cubic-rhombohedral transition in this fundamental material is still not fully understood. Combining high-pressure nanoscale x-ray diffraction imaging techniques, we conducted density-functional theory (DFT) based first-principles calculations to reveal the nature of the transition. Our theoretical calculations confirm the conclusions drawn from our imaging experiments that the pressure-induced rhombohedral distortion of Fe_{1-x}O is associated with <111> stacking defects cluster and is ferroelectric in nature.

S1.00219 MAGNETISM —

S1.00220 Structural, magnetic, electronic properties of the filled skutterudite EuFe₄As₁₂, HELGE ROSNER, ANDREAS LEITHE-JASPER, WALTER SCHNELLE, MIRIAM SCHMITT, YURI PROTS, MPI CPfS Dresden, ANGELA TRAPANANTI, CORNELIUS STROM, ESRF Grenoble, YURI GRIN, MPI CPfS Dresden — The filled skutterudite EuFe₄As₁₂ has been synthesized and its structural, electronic, magnetic and thermodynamic properties have been carefully investigated. In this compound, the Fe and Eu moments order ferrimagnetically at $T_C = 151$ K, the highest magnetic ordering temperature among filled skutterudite compounds. LDA+*U* band structure calculations confirm the observed magnetic polarizations and suggest that the conduction electrons in EuFe₄As₁₂ have a large spin polarization, although slightly smaller than in the isostructural EuFe₄Sb₁₂. We present a joint experimental and theoretical study of the electronic and magnetic properties for both compounds, including the isostructural EuFe₄P₁₂, where the exchange of the pnictide can be considered as chemical pressure. To separate the influence of mere volume effects and a change of the pnictide we also studied the behaviour under hydrostatic pressure for EuFe₄As₁₂, both experimentally and theoretically.

S1.00221 Bi_{3-x}M₃O₁₁+? (M=Cr, Rh, Ir, Pt, Pd): A series of new KSbO₃-type structural magnetic materials, WEI YI, National Institute for Materials Science — KSbO₃-type family is interesting because it can adopt three interpenetrating networks with the composition changing from ABO₃ (KSbO₃ and KIrO₃) to ABO_{3.667} (Bi₃Ru₃O₁₁, La₃Ru₃O₁₁, and Bi₃Ga₃Sb₂O₁₁). Recently Belik et. al reported a new KSbO₃-type random ferrimagnet Bi₃Mn₃O₁₁ with high T_C . Here we reported a series of new KSbO₃-type structural materials Bi_{3-x}M₃O₁₁+? (M=Cr, Rh, Ir, Pt, Pd) synthesized by high pressure and high temperature (HPHT). We investigated the effects of oxygen content on the structural, physical, and chemical properties of these materials, because a wide variation of ? value (changed from -0.5 to 0.6) in this system keeps the same cubic structure. In addition, we also studied the effects of Bi content on the structure, physical, and chemical properties. The value of x was changed from 0 to 0.4 in Bi_{3-x}Cr₃O₁₁+?.

S1.00223 ABSTRACT WITHDRAWN —

S1.00224 Electronic and Magnetic Structures in 2D Graphene and BN Nanoflakes¹, WEI-MING SHI, MING JIANG², Department of Physics, Yantai University — The two-dimensional nanomaterials have been attracting great attention for potential applications. Using first-principles calculations, we have studied the geometric and electronic properties of zigzag graphene nanoflake(ZGNF)and single-layer BN nanoflake (ZBNF)before and after hydrogen and oxygen adsorption. The interplay between atomic adsorption, crumpling structures, zigzag edges and magnetic structures has been investigated systematically. Our calculated results show that the total magnetic moments of the ZGNF with the adsorbed atoms increase significantly. The adsorbed atoms induce the crumpling structures and central spin polarization, while the magnetic orders of zigzag borders are controlled. A detailed electronic structure analysis is given. The single-layer BN nanoflake has a special crumpling struture different from the ZGNF. The left-right symmetry of atomic height displacements is broken. This study demonstrates a new approach to manipulate the properties of 2D nanomaterials. This work was supported by the SRFROCS,SEM and Shandong OYS Foundation.

S1.00225 Non-destructive generation of nano-scale periodic pinning potentials for magnetic domain walls: a way to bias domain wall propagation, PETER METAXAS, School of Physics, University of Western Australia, PIERRE-JEAN ZERMATTEN, Spintec, Grenoble, France, RAFAEL NOVAK, JEAN-PIERRE JAMET, RAPHAEL WEIL, STANISLAS ROHART, JACQUES FERRE, ALEXANDRA MOUGIN, Labo. de Phys. des Solides, CNRS/Universite Paris-Sud 11, France, ROBERT STAMPS, School of Physics, University of Western Australia and SUPA - School of Physics and Astronomy, Uni. Glasgow, UK., VINCENT BALTZ, BERNARD RODMACQ, GILLES GAUDIN, Spintec, Grenoble, France — The stray magnetic field of an array of ferromagnetic nanodots is used to generate a spatially periodic pinning potential for domain walls moving through a physically separate, weakly disordered, magnetic layer lying beneath the array. This technique represents a non-destructive method to create tunable and localised pinning sites for domain walls which are consequently subject to co-existing (but independent) periodic and disordered pinning potentials. Beyond the fundamentally attractive application of creating a model experimental system to study interface motion through multiple co-existing pinning potentials, our system interestingly exhibits many characteristics that are normally associated with exchange bias. This is a direct result of the fact that pinning effects induced by the periodic pinning potential depend upon the polarity of the applied magnetic field which drives the domain wall motion, a phenomenon which manifests itself in field-polarity-dependent domain wall mobilities and profiles.

S1.00226 Probing antiferromagnetism in NiMn/Ni/(Co)/Cu₃Au(001) single-crystalline epitaxial thin films, M. YAQOUB KHAN, CHII-BIN WU, WOLFGANG KUCH, Freie Universität, Institut für Experimentalphysik, D-14195 Berlin, Germany — Antiferromagnetism of equi-atomic single-crystalline NiMn thin film alloys grown on Ni/Cu₃Au(001) is probed by means of magneto-optical Kerr effect (MOKE). Thickness-dependent coercivity enhancement of NiMn/Ni/Cu₃Au(001) showed that 7 atomic monolayers (ML) NiMn order antiferromagnetically at room temperature. It is found that NiMn can couple to out-of-plane (OoP) as well as in-plane (IP) magnetized Ni, the latter stabilized by Co under-layer deposition. The antiferromagnetic (AFM) ordering temperature (T_{AFM}) of NiMn coupled to OoP Ni is found to be much higher (up to 110 K) than in the IP case, for otherwise identical interfacial conditions. This is attributed to the 'magnetic proximity effect' in which the ferromagnetic (FM) layer substantially influences the T_{AFM} of the adjacent AFM layer and can be explained by either (i) a higher interfacial coupling strength or/and (ii) more thermally stable NiMn distorted spin structure when coupled to Ni magnetized in OoP direction than in IP. An exchange-bias effect could only be observed for the thickest NiMn film studied (35.7 ML); the exchange-bias field is higher in the OoP exchange-coupled system than in the IP one due to the same reason/s.

S1.00227 Tunable carrier spin polarization in PbMnS through quantum confinement¹, GEN LONG, HONGWANG ZHANG, HUI XING, BIPLOB BARMAN, YUTSUNG TSAI, ATHOS PETROU, HAO ZENG, Department of Physics, University at Buffalo-SUNY — We report magneto-photoluminescence studies on manganese-doped lead sulfide ($\text{Pb}_{1-x}\text{Mn}_x\text{S}$, $x = 0$ to 5%) quantum dot system synthesized by solution-phase chemical method. The size (3 to 15nm), temperature (7K to 100K), magnetic field (0 to 7T), and laser power dependence (1mW to 20mW) of photoluminescence were systematically investigated, with a focus on carrier spin polarization. Depending on the sizes and growth conditions, the spin polarization can be tuned from being positive to negative. Core/shell structured quantum dots with Mn^{2+} ions doped in the core or shell were also studied. The sign change in the spin polarization suggests tunable exchange interactions caused by quantum confinement effect and wave function engineering through heterostructure design.

S1.00228 Spin Dynamics in Recombinant H-chain Ferritin Reconstituted with 500Fe/Protein¹, GEORGIA PAPAETHYMIU, Villanova University — Ferrihydrite mineral cores averaging 500 Fe/protein shell were grown within recombinant human H-chain ferritin and characterized by Mössbauer spectroscopy. At 4.2 K, two magnetic phases ascribed to iron at surface and interior sites of the antiferromagnetic nanolattice of the mineral core were identified, registering hyperfine fields of 445 kOe and 486 kOe, respectively. With increasing temperature, from 4.2 K to 20 K, their values decrease at widely different rates; at a rate of 3.52 kOe/K for interior and 19.33 kOe/K for surface sites, before spectral lines collapse to quadrupolar doublets at a blocking temperature of $T_B = 22$ K. Below T_B , spin relaxation at interior sites is consistent with the theory of collective magnetic excitations of a superparamagnetic particle, whereas spin dynamics at surface sites are more consistent with theories of many-spin nano-magnet systems with greater complexity in the potential energy landscape that supports low energy spin-wave excitations. The entire Mössbauer temperature spectral profile will be presented and discussed in the light of the above observations.

S1.00229 Magnetic Anisotropy of GaAs/Fe/Au Core-Shell Nanowires Grown by MBE, KRITSANU TIVAKORNASATHORN, RICHARD PIMPINELLA, VU NGUYEN, XINYU LIU, MALGORZATA DOBROWOLSKA, JACEK FURDYNA, Department of Physics, University of Notre Dame — In order to increase the storage density of magnetic memories while maintaining thermal stability, new types of recording media and technologies need to be explored. In this context, perpendicular recording geometry is among the most attractive ideas. In this work we demonstrate a novel method of fabricating such perpendicular media, in the form of GaAs/Fe/Au core-shell nanowires (NWs) grown by molecular beam epitaxy on GaAs(111)B substrates. Scanning electron microscopy images show that the Fe shell has successfully coated the sidewalls of GaAs nanowires. Magnetic anisotropy of GaAs/Fe core-shell NWs was studied by ferromagnetic resonance and by superconducting quantum interference device (SQUID) magnetometry. Our results show that the magnetic anisotropy of this novel core-shell NW system cannot be simply described by any known theory, as revealed by our attempts to perform micromagnetic simulation using the object oriented micromagnetic framework (OOMMF). The observed features thus suggest the existence of a domain structure that is specific to this new system. We will now attempt to identify the domain structure of this complex system by magnetic force microscopy.

S1.00230 Anomalous field dependence of magnetoresistance in magnetic multilayers based on the Fibonacci sequence¹, LEONARDO DANTAS MACHADO, CLAUDIONOR GOMES BEZERRA, MARCIO ASSOLIN CORREA, CARLOS CHESMAN, Departamento de Física Teórica e Experimental - UFRN, Brazil, JOHN E. PEARSON, AXEL HOFFMANN, Materials Science Division, Argonne National Laboratory, USA — The discovery of giant magnetoresistance and concomitant effects such as oscillatory exchange coupling in magnetic multilayers was the starting point of the spintronics era. In the present study, a multilayer of Fe and Cr was designed, using the Fibonacci sequence for the growth of the non-magnetic spacers. Using the gradient method we simulated the magnetic field dependence of these nanostructures for in-plane magnetic fields. The simulations included magnetocrystalline anisotropy for the [100] and [110] directions, as well as bilinear and biquadratic exchange coupling. The resultant magnetization and magnetoresistance behavior shows unusual behavior, such as a Devil's staircase for the magnetization and increasing magnetoresistance with increasing applied magnetic fields. When the ratio of the biquadratic to bilinear coupling exceeds 30% the magnetic field response is expected to show even fractal behavior. These numerical simulations will also be compared to experimental measurements on samples prepared with nominally the same thicknesses.

S1.00231 Large exchange anisotropy in nanostructured $\text{Cu}_{30}\text{Mn}_{70}$ ribbons¹, J. MARION, F. JIMÉNEZ-VILLACORTA, L.H. LEWIS, Northeastern University Department of Chemical Engineering — Exchange bias (H_{ex}), arising from coupling between antiferromagnetic (AFM) and ferromagnetic (FM) materials, is a diagnostic metric of magnetic interactions in inhomogeneous systems. An extremely large H_{ex} of 10 kOe is found in the rapidly-solidified alloy $\text{Cu}_{30}\text{Mn}_{70}$ at 10 K [1-2], but disappears at temperatures above the system blocking temperature of 123 K. X-ray diffraction reveals the presence of two well-crystallized FCC γ -phases with cubic a-parameters 3.744 and 3.750 Å, unit cell volumes of 52.5 and 52.7 Å³, respectively, and a crystallite size of ~30 nm. We hypothesize that the γ -phase with larger a-parameter is Mn-rich while the other is Mn-poor. The observed magnetic behavior is attributed to exchange interactions between Mn-rich regions where AFM coupling between nearest-neighbor Mn atoms dominates, and Mn-poor regions where FM coupling between next-nearest-neighbors dominates [1]. Compositional fluctuations result in an additional cluster-glass-like freezing behavior due to magnetically frustrated interactions between Mn atoms [2].

S1.00232 Spin polarized surface states on stepped magnetic surfaces: ab-initio approach, OLEG STEPANYUK, OLEG POLYAKOV, ALEXANDER SALETSKY, Moscow State University, WOLFRAM HERGERT, Martin-Luther-Universität Halle-Wittenberg — It was shown that surface state electrons become spin polarized above magnetic layers and nanoislands [1]. In the present work we perform the state of the art ab-initio studies of surface state electrons at steps of magnetic metals. We focus on steps of 3d metals on Cu(111) surface. We have revealed a spin-dependent charge transfer at step edges which is explained by Smoluchowski effect. Strongly inhomogeneous spin polarization of surface states [1] at steps is revealed. Our results indicate that tunneling magnetoresistance at steps can exhibit very strong changes at the atomic scale.

S1.00233 Core/Shell and High Aspect Ratio Magnetic Oxide Nanoparticles for Antenna Applications, THOMAS F. EKIERT, JR., Air Force Research Lab - WPAFB, Universal Technology Corporation, MATTHEW O'MALLEY, Air Force Research Lab - WPAFB, BRANDON YOCUM, JENNIFER LIPPOLD, MALLORY LYLE, ANGELA GRINER, CORY FLYNN, ANNA NICKEL, Air Force Research Lab - WPAFB, Southwestern Ohio Council for Higher Education, MAX D. ALEXANDER, JR., Air Force Research Lab - WPAFB — Improved antenna gain, reduced antenna aperture size, and improved bandwidth are of interest to an increasingly mobile world. To obtain these improvements our efforts are directed at developing new magnetic oxide nanoparticle/polymer composites with modifiable permeability and permittivity and low electrical losses. Our approach consists of producing core/shell and shape controlled magnetic nanoparticles. Methods of synthesis utilize microwave and traditional heating to perform hydrothermal and solvothermal reactions. Decomposition of metal acetylacetonates is performed using various alcohols resulting in spherical nanoparticles with diameters of ≈ 8 -16 nm and 3-7 nm for Fe_3O_4 and CoFe_2O_4 , respectively. Microwave methods result in similar particles, but are produced in an hour or less as compared to 48 hrs via the traditional solvothermal method. Successive growths are used to produce larger monolithic particles as well as core/shell systems where exchange coupling between the core and shell is observed. Hexaferrite particles have been produced via hydrothermal synthesis, while high aspect ratio Fe_3O_4 nanoparticles (≈ 10 -100 nm) produced via hydrothermal synthesis result in nanoneedles with high μ_r .

S1.00234 Magnetism and structure of amorphous Co-W alloyed nanoparticles, ADRIANA FIGUEROA, JUAN BARTOLOME, ICMA - CSIC, Spain, LUIS M. GARCIA, ICMA - Universidad de Zaragoza, Spain, FERNANDO BARTOLOME, ICMA - CSIC, Spain, CESAR MAGEN, ALFONSO IBARRA, INA - Universidad de Zaragoza, Spain, LUISA RUIZ, JOSE M. GONZALEZ-CALBET, Universidad Complutense, Spain, FREDERIC PETROFF, C. DERANLOT, CNRS - Thales, France, SAKURA PASCARELLI, ESRF, France, PETER BENCOK, Diamond Synchrotron, UK, NICHOLAS B. BROOKES, FABRICE WILHELM, ANDREI ROGALEV, ESRF, France — W-capped Co nanoparticles dispersed in an alumina matrix are studied by means of high-resolution transmission electron microscopy, extended x-ray absorption fine structure, SQUID-based magnetic measurements, ac magnetic susceptibility, and x-ray magnetic circular dichroism. Results show the formation of amorphous Co-W alloy nanoparticles, the magnetic properties of which are modified by the amount of W or Co present in the samples. The average Co magnetic moment depends on the number of W atoms surrounding it. Co-W particles show superparamagnetic behavior and are described as an array of noninteracting particles with random anisotropy axes and an average moment per particle proportional to the particle volume and to the average Co moment for each alloy composition. Values of the magnetic anisotropy constant of the particles are on the order of 10^6 erg/cm³, higher than that of bulk Co. Evidence of short-range ordering within each amorphous particle is found that provides insight of the origin of their magnetic anisotropy.

S1.00235 Competition between quantum criticality and Fermi liquid behavior revealed by transport measurements in ultrapure $\text{Sr}_3\text{Ru}_2\text{O}_7$, JAN BRUIN, HIDEAKI SAKAI, University of St Andrews, ROBIN S. PERRY, University of Edinburgh, ANDREW P. MACKENZIE, University of St Andrews — The layered perovskite metal $\text{Sr}_3\text{Ru}_2\text{O}_7$ has gained considerable interest since the discovery of its field-tuned quantum criticality [1] and the subsequent discovery of a new electronic phase with a high magnetoresistive anisotropy, consistent with the existence of an electronic nematic fluid [2]. Further studies have explored the properties of the “normal state” from which the anisotropic phase emerges in terms of thermodynamics [3] and quantum oscillations [4], but a comprehensive study of the transport properties of the purest samples has so far been lacking. Here, we present the first study of the normal state resistivity of ultrapure $\text{Sr}_3\text{Ru}_2\text{O}_7$, involving temperature control over more than two orders of magnitude and a 15T magnet system. The high signal to noise of this measurement allows for precise extraction of the temperature dependence exponent and provides detailed understanding of the transport signatures of field-tuned quantum criticality.

S1.00236 The Influence of Layer Thickness-Ratio on Magnetoresistance in $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3/\text{La}_{1/3}\text{Ca}_{2/3}\text{MnO}_3$ Exchange Biased System, MARIA ELENA GOMEZ, SANDRA MILENA DIEZ, LINA MARIA CUARTAS, Universidad del Valle, LORENA MARIN, Ina Universidad de Zaragoza, PEDRO PRIETO, CENM Excellence Center for Novel Materials — Isothermal magnetic field dependence of the resistance in $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$ (F-LCMO)/ $\text{La}_{1/3}\text{Ca}_{2/3}\text{MnO}_3$ (AF-LCMO) bilayer and AF-LCMO/F-LCMO/AF-LCMO trilayer at temperatures below Néel temperature of the antiferromagnetic layer were carried out to study the thickness layers influence on magneto transport properties. We grew multilayers using a high oxygen pressure sputtering technique. We systematically varied the thickness of the F-LCMO layer, t_F , maintaining constant the thickness of the AF-LCMO layer, t_{AF} . We studied the influence of the thickness ratio t_F/t_{AF} on the ZFC and FC magnetoresistance (MR) loops. H_{FC} was varied from 100 Oe to 400 Oe. We found that MR has hysteretic behavior as observed in $[\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3/\text{La}_{1/3}\text{Ca}_{2/3}\text{MnO}_3]_N$ superlattices, where MR increases with the increasing field from $H=0$ to a maximum and then it decreases continuously. The position and magnitude of the maximum is not symmetric with respect to the axis $H=0$ for both FC and ZFC loops. We found that magnetoresistance behavior of the bilayer and trilayer is thickness-ratio dependent for both ZFC and FC loops.

S1.00237 Micromagnetic simulations and experimental calibration of magnetic behavior in multiferroic BiFeO_3 , DIANA QIU, KHALID ASHRAF, SAYEED SALAHUDDIN, University of California, Berkeley — BiFeO_3 (BFO) is a magneto-electric multiferroic that exhibits ferroelectric and antiferromagnetic (AFM) ordering at room temperature. BFO films are frequently coupled to a ferromagnet (FM) layer grown on the BFO surface, but the behavior of the magnetization in BFO films and at the BFO/FM interface is not understood. We propose a micromagnetic model for the magnetization in BFO in which spin canting throughout the film, induced by the Dzyaloshinskii-Moriya (DM) effect, creates weak ferromagnetism on the BFO surface. This surface ferromagnetism is significantly enhanced by an exchange interaction with the FM at the BFO/FM interface. We perform OOMMF micromagnetic simulations of BFO/CoFe bilayers and reproduce experimentally reported one-to-one mapping between BFO and CoFe domains as well as enhanced magnetic moment on the BFO surface, on the order of $0.5 \mu_B$ per unit cell. From this model, we can extract AFM/FM exchange energies and DM energies by fitting experimentally reported values for BFO surface magnetic moment and hysteresis. We also demonstrate that magnetization switching of the BFO domains can induce switching in the FM. We reproduce experimentally observed 180° total magnetization switching through 90° switching in stripe-like domains.

S1.00238 Growth of ferromagnetic $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$ / ferroelectric BaTiO_3 heterostructures¹,

MARIA ELENA GOMEZ, JOHN EDWARD ORDOÑEZ, WILSON LOPERA, Department of Physics, Universidad del Valle, Cali, Colombia, PEDRO PRIETO, CENM Excellence Center for Novel Materials, Colombia, LORENA MARIN, J.A. PARDO, L. MORELLON, P. ALGARABEL, Instituto de Nanociencia de Aragón, Universidad de Zaragoza, Spain — Multiferroic materials exhibiting simultaneous ferroelectricity and ferromagnetism have potential applications in information storage and in the emerging field of spintronics. Ferromagnetic / ferroelectric multilayers could be a way to obtain a multiferroic heterostructure. We addressed to deposit the ferromagnetic phase of the $\text{La}_{1-x}\text{Ca}_x\text{MnO}_3$ and the ferroelectric BaTiO_3 seeking a multiferroic properties in these hetero structures. We have optimized the growth parameters for depositing $\text{BaTiO}_3(\text{BTO})$ / $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3(\text{LCMO})$ / $(001)\text{SrTiO}_3$ by pulsed laser deposition (PLD) at pure oxygen atmosphere and a substrate temperature of 820 °C. The bilayer structure and microstructure were studied by x-ray diffraction (XRD) and atomic force microscopy (AFM). For individual layers, lattice parameter is $a_{\text{BTO}}=4.068$ Å, and $a_{\text{LCMO}}=3.804$ Å, whereas in the bilayer, Bragg peaks for LCMO maintain its position but BTO peak shift to lower Bragg angle indicating a strained BTO film. Magnetization and polarization measurements indicate a possible multiferroic heterostructures

S1.00239 Characterization of Nano-oxidation Lithography on $\text{La}_{0.7}\text{Ba}_{0.3}\text{MnO}_3$ Thin Films Grown by Pulse-Laser-Deposition

EKEMBU KEVIN TANYI, DAVID SCHAEFER, RAJESWARI KOLAGANI, PARUL SRIVASTAVA, Towson University — Nano-oxidation using Atomic Force Microscopy has been used to produce nano-scale patterns on a variety of materials, including semiconductors, insulators, metals and superconductors. Perovskite Oxide thin films have demonstrated unique material characteristics. The ability to make localized modifications on these films would allow nanofabrication of devices utilizing these unique properties. In this study, the atomic force microscope was used to modify the surface of $\text{La}_{0.7}\text{Ba}_{0.3}\text{MnO}_3$ thin films grown using Pulsed Laser Deposition Techniques. Surface patterns were produced and studied as a function of humidity, applied tip voltage, temperature, and growth conditions. Reproducible patterns were produced using both positive and negative tip voltages. Two growth modes were observed. A moderate growth rate was common for positive tip voltages up to 15 V (at $T=75.1\pm1$; $H=78\pm2\%$) which allowed the controlled formation of features considerably larger than those produced on materials like silicon. Additionally, a significantly larger growth rate was observed for negative tip voltages exceeding -12V. This growth mode provides the potential to produce structures at significantly higher write speeds, making these manganese films candidates for data storage devices.

S1.00240 Finite-Size Scaling Effects in Chromia thin films¹, WILL ECHTENKAMP, XI HE, CHRISTIAN BINEK, Department of Physics and Astronomy and Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln — Controlling magnetism by electrical means remains a key challenge in the area of spintronics. The use of magnetoelectrically active materials is one of the most promising approaches to this problem. Utilizing Cr_2O_3 as the magnetoelectric pinning layer in a magnetic heterostructure both temperature assisted and isothermal electrical control of exchange bias have been achieved [1,2]. Interestingly, this ME switching of exchange bias has only been achieved using bulk Cr_2O_3 crystals, isothermal switching of exchange bias using thin film chromia remains elusive. We investigate the origin of unusually pronounced finite-size scaling effects on the properties of Cr_2O_3 grown by Molecular Beam Epitaxy; in particular we focus on the different temperature dependencies of the magnetic susceptibility of bulk vs. thin film chromia, the change in Neel temperatures, and the implications for the magneto electric properties of chromia thin films.

S1.00241 ABSTRACT MOVED TO A13.00014 —

S1.00242 Control of noise in magnetic multilayers by spin torque, ADNAN REBEI, King Abdullah Institute for Nanotechnology — In this work we show that the stability of magnetic nanostructures can be enhanced by time-dependent spin momentum transfer. Building reliable magnetic devices at smaller scales need to address the issue of thermal noise. Using two commonly studied magnetic systems with multiple stable states at zero temperature as examples, we show that periodic spin torques can enhance the stability of the system and hence suppress the noise due to interwell transitions. In the case of weak periodic spin torques, stochastic resonance which is usually associated with ac magnetic fields is also manifested for non-conservative torques. In more complex systems with a relatively low energy barrier, it is shown that high frequency spin torques can inhibit interwell transitions and in effect suppress the telegraph noise due to the switching between neighboring states.

S1.00243 Full Field-Frequency Study of Standing Spin Wave Modes in FM / NM / FM

Trilayers¹, PETER WARNICKE, JAVIER PULECIO, SHAWN POLLARD, YIMEI ZHU, DARIO ARENA, Brookhaven National Laboratory — Spin waves constitute an attractive avenue for spintronic devices as they can be used to carry information through magnetic media as well as to store information in form of localized modes. As a way of manipulating these entities, external microwave fields can be employed. For a given precession frequency, the amplitude of the localized spin wave mode in a single ferromagnetic layer is determined by the confining geometry and applied magnetic field strength. By introducing a non-magnetic spacer layer into the layer, the development of spin waves can be modified in a frequency range by varying the spacer layer thickness [1,2]. Here we investigate the role of the spacer layer thickness in a Permalloy/Copper/Permalloy trilayer by means of full field-frequency ferromagnetic resonance (FMR) spectroscopy.

S1.00244 Electronic and Optical properties of Mn δ -doping InGaAs/GaAs Quantum Wells¹,

UDSON MENDES, JOSÉ BRUM, Department of Condensed Matter Physics, Institute of Physics Gleb Wataghin, State University of Campinas, Campinas - São Paulo, Brazil — Recent magneto-optical measurements in InGaAs quantum wells (QWs) with GaAs barriers with δ -doped layers of Mn and C, show a strong oscillations of circularly polarized QW emission as a function of the magnetic field. The oscillations amplitude increases with the Mn content and they persist up to 25 K [Appl. Phys. Lett. 98, 251901 (2011)]. In order to understand these magneto-oscillations we studied the electronic and optical properties of the two-dimensional hole gas (2DHG) formed in the QW. The holes are provided by both Mn and C doping. We used the spin-density functional theory within the $\mathbf{k}\cdot\mathbf{p}$, the envelope function and the virtual crystal approximations to describe the electronic states of the system. The $sp-d$ interaction was described by the Zener kinetic-exchange model. Our results show that when an external magnetic field is applied a spin-polarized 2DHG is formed at the Mn δ -doped layer, inducing an effective magnetic field. This field affects the charge redistribution of the system inducing oscillations in the Fermi and energy levels, and consequently in the QW emission. The strength of these oscillations is strongly dependent on the nature of the Mn doping, in particular the distance between the QW and the Mn layers.

¹This work is supported by FAPESP and CAPES.

S1.00245 Structural and magnetic properties of GaAs-MnAs nanowires grown by MBE¹, A. SIUSYS, A. RESZKA, P. DZIAWA, B.J. KOWALSKI, P. DLUZEWSKI, H. PRZYBYLINSKA, M. SAWICKI, Institute of Physics, Polish Academy of Sciences, Warsaw, Poland, J. SADOWSKI, MAX-Lab, Lund University, Lund, Sweden, Institute of Physics, Polish Academy of Sciences — Ferromagnetic (FM) Nanowires (NWs) have been proposed recently as a base of a new type of nano-magnetic memory structures. In this context, the investigations of NWs combining FM materials with commercially used semiconductors (SCs) like Si or GaAs are desirable. NW structures of GaAs combined with (Ga,Mn)As FM SC and MnAs FM metal were grown by MBE. Primary core GaAs NWs growth was induced by different nanocatalysts on two substrates for comparison reasons: by the autocatalytic growth mode on Si(100), Si(111) and by Au nanodroplets induced catalytic growth on GaAs(111)B. In both cases NW cores of GaAs were grown at high temperature (550 C for GaAs(111)B and 600 C for Si). The (Ga,Mn)As and MnAs shells were grown on both types of primary GaAs NW cores at low temperature (250 C). Structural properties of the core-shell GaAs-(Ga,Mn)As NWs were investigated by electron microscopy (SEM, TEM) and magnetic properties were studied by SQUID magnetometry and FM resonance. The NWs grown on GaAs(111)B are thinner (50 nm), shorter (3 microns) and denser than the NWs grown on Si (typical diameters of 100 nm, lengths up to 15 microns). The FM behavior observed in these NW structures up to room temperature is related rather to MnAs nanoclusters than to individual NW.

¹This work has been supported by the EC Network SemiSpinNet

S1.00246 Electrical spin injection and detection in Si nanowires¹, SHIXIONG ZHANG, YAN LI, SHADI A. DAYEH, DARRYL L. SMITH, SCOTT A. CROOKER, S. TOM PICRAUX, Los Alamos National Laboratory — While electrical spin injection and detection in bulk Si has now been established, the availability of high quality single crystalline silicon nanowires has stimulated considerable interest in demonstrating spin-polarized transport in these 1-dimensional structures. Here, we report our efforts to electrically inject spin-polarized electrons from cobalt contacts into n-type silicon nanowires through Al_2O_3 tunnel barriers. The electrically doped nanowires were synthesized by the vapor-liquid-solid process with a cold wall chemical vapor deposition system using silane and phosphine precursors. Low temperature magneto-transport studies have shown spin-valve like behavior in both two-terminal and four-terminal lateral devices. The spin-valve signal as functions of temperature and bias voltage will be discussed. We will also show the influence of defects and trap states on the stability of nanowire devices.

S1.00247 Bond operator theory for the frustrated anisotropic Heisenberg antiferromagnet on a square lattice¹, ANTONIO PIRES, Universidade Federal de Minas Gerais — In this work we use the bond operator formalism in a mean field approximation to study quantum phase transitions in the $S = 1$ Heisenberg antiferromagnet with single ion anisotropy up to the next-nearest neighbor coupling (the J1-J2-J3 model) on a square lattice. The model features a complex $T = 0$ phase diagram, whose ordering vector is subject to quantum corrections with respect to the classical limit. The phase diagram shows a quantum paramagnetic phase situated among Néel, spiral and collinear states.

¹This work was partially supported by CNPQ.

S1.00248 Behavior of the overlap distribution of various spin glasses at low temperature, JULIO F. FERNÁNDEZ, Universidad de Zaragoza, JUAN J. ALONSO, Universidad de Malaga — Numerical results for the probability distribution, $P(q, T)$, of the spin-overlap q as a function of temperature T , is reported for several randomly frustrated systems. These include (i) random bond Ising systems, such as the Edwards-Anderson spin-glass model, (ii) site diluted systems which are geometrically frustrated, such as FCC lattices with 40% of their sites occupied with up-down spins, and (iii) random-field systems. $P(q, T)$ stands for an average of $P_{\mathcal{J}}(q, T)$ over many system samples with different realizations of quenched randomness $\mathcal{J}$. We also report statistical fluctuations of $P_{\mathcal{J}}(q, T)$ which are relevant to the issue of self-averaging.

S1.00249 Second Frustration for Artificial Spin Ice, CRISTIANO NISOLI, TAMMIE NELSON, Theoretical Division, Los Alamos National Laboratory — Since its introduction six years ago, artificial spin ice has been employed to successfully study frustration and disorder, to explore extensions of thermodynamics to granular systems, to investigate topological defects and information encoding, and has become ground for direct imaging of “magnetic monopoles.” The research has concentrated so far on a few basic geometries (square, ladder, honeycomb, triangular) in which the frustration of the magnetic interaction at the vertices could (or not) bring about a degeneracy. Here we propose new topologically non-trivial geometries, which we call “of second frustration.” In these arrays each vertex, while frustrated, has a unique low energy configuration, and is therefore non degenerate; yet a second frustration is regained globally and vertex excitations are topologically protected on loops inside the array. These topological excitations, which control the entropy, cannot be suppressed, can move, merge and exchange topological charge. As novel, more dynamical artificial spin ice is being developed by many, these new lattices could provide an interesting playground for driving and controlling topological excitations, and for tailor-design of probe-response properties.

S1.00250 Low temperature spin glass transition in Gallium ferrite single crystals, SOMDUTTA MUKHERJEE, RAJEEV GUPTA, Department of Physics, Indian Institute of Technology Kanpur, ASHISH GARG, Materials Science and Engineering, Indian Institute of Technology Kanpur — Magnetoelectric gallium ferrite (GaFeO_3 or GFO) manifests close to room temperature ferrimagnetism owing to inherent cationic site disorder in an otherwise antiferromagnetic ground state structure. In GFO, Fe ions at Fe1 and Fe2 sites are antiferromagnetically coupled while Fe and Ga at Fe2 and Ga2 sites respectively are ferromagnetically coupled. Ga1 site is magnetically inactive. Here, we present a detailed study to probe phase transitions in GFO using ac and dc magnetic characterization methods to demonstrate spin glass behavior in GFO below 200 K. Our dc magnetization measurement exhibits that while GFO undergoes standard para (PM) to ferromagnetic (fM) transition at $T_c \sim 290$ K, splitting between field cooled and zero-field cooled plots is observed at low temperatures hinting at the spin-glass like behavior. Further, temperature dependent ac susceptibility measurements at different frequencies and at different dc fields demonstrate that the system exhibits a non-equilibrium canonical spin glass (SG) state below the spin glass transition temperature ~ 210 K. The spin glass state has been further characterized by memory effect and aging measurements. The origin of such a spin-glass phase is proposed to arise from a network of geometrically frustrated spin system attributed to combination of antiferromagnetic interaction among the Fe ions in the two Fe sites and Ga2 site as well as inherent cation site disorder.

S1.00251 Spin $S = 1$ “Quantum spin liquid”: quantum criticality in $6\text{H-B-Ba}_3\text{NiSb}_2\text{O}_9$, GANG CHEN, MICHAEL HERMELE, LEO RADZIHOVSKY, CU Boulder — We present a minimal model for a recently discovered material $6\text{H-B-Ba}_3\text{NiSb}_2\text{O}_9$ which was proposed as a candidate for $S = 1$ quantum spin liquid on a triangular lattice. Our spin-1 model lies on a stacked multilayer triangular lattice. In our minimal model, we point out the competition between Heisenberg exchange interactions, which favor magnetic ordering, and the easy-plane single-ion anisotropy, which favors a uniform quantum paramagnetic state with $S^z = 0$ state at each site. We argue that the system is close to the quantum critical point separating these two phases and on the quantum paramagnetic phase side. Viewing the system as a three dimensional multilayer structure, we find that the frustrated interlayer and intralayer exchange interaction induces nodal lines of low energy spin excitations at the quantum critical point. Moreover, due to the quasi-2D nature of the system and proximity to the quantum critical point, we show there exists a broad intermediate temperature regime with linear temperature dependence of specific heat. Various other predictions and suggestions for experiments are discussed.

S1.00252 Order by disorder in kagome-type magnets¹, GIA-WEI CHERN, University of Wisconsin at Madison and Los Alamos National Lab, RODERICH MOESSNER, Max Planck Institute for the Physics of Complex Systems — Magnets on kagome lattice have been and continue to be the archetypical setting in which to study exotic order induced by geometrical frustration in theory and experiment. Approximate realizations of kagome magnet has been observed in compounds such as SCGO and herbertsmithite. Artificial kagome spin ice has also been created using lithographically fabricated arrays of nanoscale magnets. The frustration comes from the fact that nearest-neighbor spin interactions on a network of corner-sharing triangles cannot be satisfied simultaneously, leading to a huge degeneracy in its classical ground state, for both discrete and continuous spins. Here, we present some recent progress in simulating numerically, and analysing field-theoretically, kagome magnets with differing sets of interactions.

¹GWC acknowledges the support of ICAM and NSF Grant DMR-0844115.

S1.00253 Exact Diagonalization of the Kondo Necklace Model on a Triangular Lattice, ARA GO, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University, GUN SANG JEON, Department of Physics, Ewha Womans University, MOO YOUNG CHOI, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University — We consider the Kondo necklace model on a triangular lattice. The interplay of magnetic ordering and Kondo screening is investigated through the use of exact diagonalization of finite clusters with periodic boundary conditions. In the absence of Kondo screening, the system is in the magnetically ordered phase whereas the magnetic moments reduce monotonically as the screening strength is increased. It is found that the system has a unique ground state in the entire range of the parameters studied, which excludes the possibility of partially ordered degenerate ground states. We also discuss the effects of quantum fluctuations in the model, with emphasis on the lifted degeneracy of partially ordered states.

S1.00254 Tensor network simulation of phase diagram of frustrated J1-J2 Heisenberg model on a checkerboard lattice, YANGHAO CHAN, Physics Department, University of Michigan, YONGJIAN HAN, Key laboratory of quantum information, University of Science and Technology of China, LUMING DUAN, Physics Department, University of Michigan — We use the recently developed tensor network algorithm based on infinite projected entangled pair states (iPEPS) to study the phase diagram of frustrated antiferromagnetic J1-J2 Heisenberg model on a checkerboard lattice. The simulation indicates a Neel ordered phase when $J_2 < 0.88J_1$, a plaquette valence bond solid state when $0.88 < J_2/J_1 < 1.11$, and a stripe phase when $J_2 > 1.11J_1$, with two first-order transitions across the phase boundaries. The calculation shows the cross-dimer state proposed before is unlikely to be the ground state of the model, although such a state indeed arises as a metastable state in some parameter region.

S1.00255 Fabrication of organic spin-valve devices using indirect deposition, SHEN WANG, YUJUN SHI, LI LIN, BINBIN CHEN, FENJUAN YUE, DI WU, Nanjing University — The organic spin valves (OSVs) comprised of two ferromagnetic (FM) electrodes separated by an organic spacer are the principal device structures to study the spin-dependent transport. Normally, the top FM electrodes are directly deposited on top of the organic layer. The vaporized FM atoms can penetrate or diffuse into organic layer and form the so-called ill-defined layer, which is as thick as 80-100 nm. In this work we report a reliable method for fabricating high quality, reproducible OSVs. We use indirect deposition method, which relies on the scattering of the evaporated metallic atoms with inert gas to reduce kinetic energy, to deposit the Co electrode on top of the organic layer Alq₃. This method significantly suppresses the penetration of Co atoms into Alq₃ layer during deposition process, in comparison with devices fabricated by conventional direct deposition method. The improved Alq₃/Co interface is further confirmed by comparing the magnetic moment of depositing Co onto Alq₃ and Si substrates by indirect and direct deposition methods. And an OSV effect in La_{0.7}Sr_{0.3}MnO₃/Alq₃/Co devices is demonstrated at room temperature, indicating the improvement of spin injection efficiency at sharp Alq₃/Co interface.

S1.00256 Spin Transport in the XXZ Chain at Finite Temperature and Momentum¹, WOLFRAM BREINIG, Technical University Braunschweig, Germany, ROBIN STEINIGEWEG, J. Stefan Institute, Ljubljana, Slovenia — We investigate the role of momentum for the transport of magnetization in the spin-1/2 Heisenberg chain above the isotropic point at finite temperature and momentum [1]. Using numerical and analytical approaches, we analyze the autocorrelations of density and current and observe a finite region of the Brillouin zone with diffusive dynamics below a cut-off momentum, and a diffusion constant independent of momentum and time, which scales inversely with anisotropy. Lowering the temperature over a wide range, starting from infinity, the diffusion constant is found to increase strongly while the cut-off momentum for diffusion decreases. Above the cut-off momentum diffusion breaks down completely.

S1.00257 Chemisorption of Co-based cyanol pyridyl valence tautomers on Au(111)¹, WANDERLA SCOPEL, YIFENG CHEN, MARCO BUONGIORNO NARDELLI, Department of Physics, North Carolina State University — Organic paramagnetic bistable molecules such as transition metal valence tautomers, where a magnetic transitions can be induced by an external perturbation, are attracting considerable attention due to their potential utilization in molecular electronic and spintronic devices. Using calculations from first principle based on density functional theory we have investigated the chemisorption of Co-based cyanol pyridyl valence tautomer (VT) molecules on the Au(111) surface via a thiol head group. Among the possible adsorption sites on the Au(111) surface, we considered both the fcc hollow site and the bridge site, which are suggested to be the two lowest energy adsorption configurations in previous investigations. We have characterized the stability and the influence of the substrate bonding on the electronic and magnetic properties of the VT molecule. Moreover, by adding a top Au contact, we have studied the electron and spin transport properties of these systems.

S1.00258 Analysis on the Magnetic and Thermodynamic behavior of a Linear Magnetic Chain [Co(bpdc)(H₂O)₂].H₂O, YOUCEF HAMIDA, DUSAN DANILOVIC¹, TAN YUEN, Temple University, QIHAN GONG, JING LI, Rutgers University, DEPT. PHYSICS, TEMPLE UNIVERSITY COLLABORATION, DEPT. CHEMISTRY AND CHEMICAL BIOLOGY, RUTGERS UNIVERSITY COLLABORATION — [Co(bpdc)(H₂O)₂].H₂O (bpdc=biphenyldicarboxylate) was found to be a one dimensional ferromagnetic Co (II) chain system that orders below 5.5 K due to a weak antiferromagnetic inter-chain coupling. Classical Fisher Model (CFM), Mean Field Theory (MFT), and Ising Model (IM) were applied to the high temperature susceptibility data of [Co(bpdc)(H₂O)₂].H₂O. The fit to CFM yielded a $J/k_B = + 7.40$ K with $R^2 = 0.993$; MFT gave a $J/k_B = + 5.31$ K with a low $R^2 = 0.391$. The ratio interchain interactions (J') to that of intra-chain interactions was estimated to be $J'/J = - 0.005$. The magnetic specific heat was obtained via direct subtraction of the specific heat data for Zinc analogue from that of [Co(bpdc)(H₂O)₂].H₂O. The magnetic specific heat data was fit to the Ising Model for spin 1/2 yielding $J/k_B = + 15.27$ K. The interpretations on the spin state of the Co(II) at different temperatures in the compound are consistent with the behavior of Co(II) in other compounds with similar octahedral sites.

S1.00259 Magnetic properties of 3d transition metal-phthalocyanine molecules on oxidized Cu(110) surface, JUN HU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, CA 92697-4575 — After being extensively interesting topics in both fundamental researches and application practices for a decade, spintronics is now on its way of diversity. Molecular spintronics has attracted much attention in recent years, due to the accelerating miniaturization of electronic devices. In this work, based on first-principles calculations, we studied the electronic and magnetic properties of both isolated metal-phthalocyanines (commonly referred to as MPc) molecules (M=Mn, Fe and Co) and a single MPc molecule adsorbed on oxidized Cu(110) [O-Cu(110)] surface. We find that the easy axis of FePc molecule switches from in-plane direction to perpendicular direction when it is adsorbed on O-Cu(110) surface. However, such a switch of direction of magnetization could not be observed for MnPc and CoPc molecules which are two neighbors of FePc with one electron less and more, respectively. Furthermore, we find that the magnetization of these MPc molecules on O-Cu(110) surface are rather stable, so they could not be altered by moderate hole/electron doping. The e_g orbitals (d_{xz} and d_{yz}) of MPc molecules are found to be crucial for their magnetization on O-Cu(110) surface. **Acknowledgement.** This work was supported by DOE Grant DE-FG02-05ER46237.

S1.00260 Dependence of magnetic field and electronic transport of Mn4 Single-molecule magnet in a Single-Electron Transistor, ALVAR RODRIGUEZ, SIMRANJEET SINGH, FIROZE HAQUE, ENRIQUE DEL BARCO, University of Central Florida Department of Physics, TU NGUYEN, GEORGE CHRISTOU, University of Florida Department of Chemistry — Dependence of magnetic field and electronic transport of Mn4 Single-molecule magnet in a Single-Electron Transistor A. Rodriguez, S. Singh, F. Haque and E. del Barco Department of Physics, University of Central Florida, 4000 Central Florida Blvd., Orlando, Florida 32816 USA T. Nguyen and G. Christou Department of Chemistry, University of Florida, Gainesville, Florida 32611 USA Abstract We have performed single-electron transport measurements on a series of Mn-based low-nuclearity single-molecule magnets (SMM) observing Coulomb blockade. SMMs with well isolated and low ground spin states, i.e. $S = 9/2$ (Mn4) and $S = 6$ (Mn3) were chosen for these studies, such that the ground spin multiplet does not mix with levels of other excited spin states for the magnetic fields ($H = 0-8$ T) employed in the experiments. Different functionalization groups were employed to change the mechanical, geometrical and transport characteristics of the molecules when deposited from liquid solution on the transistors. Electromigration-broken three-terminal single-electron transistors were used. Results obtained at temperatures down to 240 mK and in the presence of high magnetic fields will be shown.

S1.00261 Magnetic characterization of a Mn6 Single-molecule Magnet, SIMRANJEET SINGH, ENRIQUE DEL BARCO, Department of Physics, University of Central Florida, Orlando, FL, MAHAMMAD ALI, Department of Chemistry, Jadavpur University, Kolkata, India — Single Molecule magnets (SMMs) are excellent candidates for the exploration of fundamental quantum effects at the nanoscale, as well as for potential applications in emerging technologies, such as quantum computation. Of particular interest are Mn6 SMMs, one of which has the highest effective energy barrier to magnetization reversal reported so far in the literature. We have performed Hall-effect magnetometry on single crystals of a new kind of Mn6 at cryogenic temperatures (>230 mK). We will discuss the dependence of the hysteresis loops on the temperature and different sweep rates of the applied magnetic field. The high saturation fields observed in this SMM will be discussed.

S1.00262 Stoner Instability in a Strongly Repulsive Fermi Gas¹, WUJIE HUANG, CHRISTIAN SANNER, EDWARD SU, AVIV KESHET, JONATHAN GILLEN, WOLFGANG KETTERLE, Center for Ultracold Atoms, Research Laboratory of Electronics, and Department of Physics, Massachusetts Institute of Technology — We study the existence of itinerant ferromagnetism using a ultracold Fermi gas with short range repulsion in a harmonic trap. A degenerate Fermi gas is rapidly quenched into the regime of strong effective repulsion near a Feshbach resonance. The spin fluctuations are monitored using speckle imaging and, contrary to several theoretical predictions, the samples remain in the paramagnetic phase for arbitrarily large scattering length. We also observe a rapid decay into bound pairs over times on the order of $10\hbar/E_F$ in a wide range of interaction strengths, which is intrinsic by the nature of Feshbach resonance and preventing the study of equilibrium phases of strongly repulsive fermions. Our work suggests that a Fermi gas with strong short-range repulsive interactions does not undergo a ferromagnetic phase transition.

S1.00263 Magnetism of Cobalt Dibromide Dihydrate and Monohydrate¹, G.C. DEFOTIS, A.S. HAMPTON, C.L. DESANTO, C.M. DAVIS, College of William and Mary — The magnetic properties of two hardly studied bromide compounds among the large family of 3d divalent transition metal halide hydrates are examined, with Co(II) the metal ion. Of interest is comparison between magnetic behaviors in the much more common dihydrate form and in the rarely made monohydrate form, as well as comparison between known properties of the far better studied chloride materials and those containing bromide. In the title dihydrate material a magnetic susceptibility maximum appears at 9.5 K, about half the temperature of a similar feature in the chloride dihydrate system. But in the title monohydrate material an enhanced susceptibility maximum appears at 15.5 K, virtually the same as in the similarly behaving chloride monohydrate system. As for chloride systems, a major difference between di- and monohydrates appears in that magnetic irreversibilities are far stronger in the latter. The magnetic susceptibility in both title systems is non-Curie-Weiss like at moderate to high temperatures, but can be accounted for well on the basis of a ground and an excited Kramers doublet, along with exchange interactions. The susceptibility in the vicinity of the maximum in the title dihydrate material is approximately accounted for with a three-dimensional Ising model.

S1.00264 Crystal structure and ferromagnetic phase transitions in $\text{CeCu}_{1-x}\text{Ge}_{1+x}$ ($0.0 \leq x \leq 0.3$)¹, W.H. LEE, S.Y. SHIH, H.H. SUNG, K.J. SYU, S.C. CHEN, National Chung Cheng University, W.H. LEE TEAM — As revealed in the powder x-ray diffraction and crystallographic data, the single phase sample in the series $\text{CeCu}_{1-x}\text{Ge}_{1+x}$ ($0.0 \leq x \leq 0.3$) crystallizes in the AlB_2 -type structure with space group $P6_3/\text{mmc}$. The maximum ferromagnetic transition temperature T_c in $\text{CeCu}_{1-x}\text{Ge}_{1+x}$, as determined from the electrical- resistivity and magnetic susceptibility measurements, is 10.6 K for the compound $\text{CeCu}_{0.8}\text{Ge}_{1.2}$. The magnetic susceptibility for each sample in $\text{CeCu}_{1-x}\text{Ge}_{1+x}$ ($0.0 \leq x \leq 0.3$) follows Curie's behavior between 100 and 300 K with an effective moment $2.6 \pm 0.1 \mu_B/\text{Ce atom}$, a value close to that of Ce^{3+} . However, the observed saturation magnetic moment values ($0.96 \sim 1.15 \mu_B$) at low temperatures for all these compounds are well less than the theoretically expected value $2.14 \mu_B$ for the free Ce^{3+} ion tangling the entire six-fold $J = 5/2$ multiplet. Subtracting the estimated phonon contribution from LaCuGe , the entropy associated with the magnetic structure of CeCuGe is found to meet the theoretical value of $R \ln 2$, which would be expected for a doublet ground state of Ce^{3+} ion in the compound CeCuGe . The reduced saturation moment in $\text{CeCu}_{1-x}\text{Ge}_{1+x}$ is reasonably ascribed to partial lifting of the 4f-electron level degeneracy.

S1.00265 Deuterated Mn and Ni Dibromide Dihydrate and Contrast with Normal Water Systems¹, K.T. TROWELL, K.C. HAVAS, M.J. VAN DONGEN, C.H. KOMATSU, D.G. CHAN, Z.D. REED, G.C. DEFOTIS, College of William and Mary — First row transition metal hydrated bromide compounds are much less studied magnetically than chlorides, and for each of the common hydration states 2, 4 or 6 waters. Examination of rarer monohydrate chlorides was initiated only more recently. Quite intriguing similarities and differences in the magnetism, with respect to that of the most closely related dihydrates especially, occur. It is of interest to extend measurements to bromide systems, especially mono- and dihydrate forms. And given the role, structural and magnetic, that hydrogen bonding can play, deuteration effects are also worth exploring (and little studied in general). Magnetic measurements on the new deuterated title systems are presented. For the deuterated Mn compound the susceptibility is of similar general appearance to that of the normal water system, but with a maximum at 2.1 K, only one-third the 6.3 K of the latter; the maximum is much larger in the deuterated system. For the deuterated Ni compound a maximum appears about 10% lower than the 6.0 K location in the normal water system, and is of moderately larger size; it is however substantially broader. Comparisons with deuterated vs normal water behaviors in related materials, where differences are often far less striking, will be made.

S1.00266 Magnetic Domain Dynamics Study in Dysprosium, SAN-WEN CHEN, HONGYU GUO, XIANGSHUN LU, University of California San Diego, SUJOY ROY, KEOKI SEU, Lawrence Berkeley National Laboratory, KARINE DUMESNIL, University H. Poincare, France, SUNIL SINHA, University of California San Diego, UNIVERSITY OF CALIFORNIA SAN DIEGO TEAM, LAWRENCE BERKELEY NATIONAL LABORATORY COLLABORATION, UNIVERSITY H. POINCARÉ, FRANCE COLLABORATION — We have studied magnetic domain fluctuations in a Yttrium-Dysprosium-Yttrium tri-layer with X-ray photon correlation spectroscopy (XPCS) in conjunction with resonant soft x-ray magnetic scattering. Dysprosium possesses a helical antiferromagnetic ordering below its Néel temperature ($T_N = 180\text{K}$) and above its Curie temperature ($T_C \sim 85\text{K}$). With resonant x-ray scattering, we observed the magnetic satellite peak at $(0,0,q_m)$ due to the helical magnetic structure. We determined the transition temperature and found a shift in T_C from the bulk value and hysteresis behavior around T_C . The transverse correlation length showed a minimum at both T_C and T_N . With the coherent x-rays, we observed magnetic speckles from both static disorder and magnetic domains. The XPCS studies as a function of temperature showed that the magnetic domains are static up to 2000 seconds time scale when $T < 175\text{K}$. Close to T_N , there appears to be slow dynamics which might be due to domain wall fluctuation.

S1.00267 Giant Electromechanical Response in Graphene Nanoribbons, NABIL AL-AQTASH, RENAT SABIRIANOV, University of Nebraska at Omaha, HONG LI, Peking University, Beijing, P.R. China, LU WANG, WAI-NING MEI, University of Nebraska at Omaha, JING LU, Peking University, Beijing, P.R. China — The demonstration of spin injection into graphene has proposed that graphene could play a role in spintronic devices. Specifically, it has been found that zigzag graphene nanoribbons (ZGNR) have spin states at their edges. In this study, first principles quantum mechanical calculations have been performed to investigate the effect of twist on the electronic, magnetic and transport properties of ZGNR. We investigate the electronic and magnetic structures of nanoribbon of ZGNR in the flat geometry and with 180° twisting. Using density functional theory coupled with nonequilibrium Green's function method implemented in SIESTA code, we examine the local magnetic moments and the quantum conductance of twisted ZGNR in its ground state (antiferromagnetic) and in case of ferromagnetic spin orientations. Our calculations show that ZGNR in its ground state is insensitive to twisted deformation, since the conductance of the twisted ZGNR is almost unchanged, as well as, no band gap change. However, we observe electromechanical switch via twisting a ferromagnetic ZGNR in hypothetical ferromagnetic nanoribbons. The transmission in a hypothetical ferromagnetic state for 4-ZGNR is 2 quantum of conductance, while the transmission becomes zero in case of oppositely polarized leads (after twisting), i.e. we observe an ideal spin valve. We relaxed both the atomic positions and the spin directions in our calculations allowing for a Bloch/Neel-like domain wall in the latter case.

S1.00268 Simulations of random defects for fast domain wall motion in ferromagnetic nanowires¹, KYLE KIMMINAU, ANDREW KUNZ, Marquette University, PHYSICS DEPARTMENT TEAM — Domain walls in ferromagnetic nanowires move slowly when driven by large magnetic fields due to a process known as Walker breakdown. During Walker breakdown vortices are formed which slow the domain wall leading to low average speeds. Vortex formation is driven by the precessional motion of the magnetic moments in the domain wall. Techniques which disturb the coherent precession can be used to disrupt Walker breakdown and therefore recover fast domain wall speeds which could be useful for future technological devices. We used a combination of micromagnetic simulation and theoretical modeling to simulate the effects of random defects (voids) on the motion of a domain wall. Simulations find there is critical defect density associated with the destruction of the breakdown. We then use a magnetostatic charge model to calculate the strength of the perturbing field, created by the defects, necessary to disrupt the precessional motion of the moment in the domain wall. For an appropriate defect density the domain walls move quickly, without experiencing breakdown or a change in magnetic structure, for applied fields at least an order of magnitude greater than the typical breakdown field.

S1.00269 Anisotropic Magnetoresistance Effects in Fe, Co, Ni, Fe₄N, and Half-Metallic Ferromagnet: A Systematic Analysis, SATOSHI KOKADO, Faculty of Engineering, Shizuoka University, Japan, MASAKIYO TSUNODA, Graduate School of Engineering, Tohoku University, Japan, KIKUO HARIGAYA, Nanosystem Research Institute, AIST, Japan, AKIMASA SAKUMA, Graduate School of Engineering, Tohoku University, Japan — We theoretically analyze the anisotropic magnetoresistance (AMR) effects of bcc Fe (+), fcc Co (+), fcc Ni (+), Fe₄N (−), and a half-metallic ferromagnet (−) [1]. The sign in each () represents the sign of the AMR ratio observed experimentally. We here use the two-current model for a system consisting of a spin-polarized conduction state and localized d states with spin-orbit interaction. From the model, we first derive a general expression of the AMR ratio. The expression consists of a resistivity of the conduction state of the σ spin ($\sigma = \uparrow$ or $\downarrow$), $\rho_{s\sigma}$, and resistivities due to s-d scattering processes from the conduction state to the localized d states. On the basis of this expression, we next find a relation between the sign of the AMR ratio and the s-d scattering process. In addition, we obtain expressions of the AMR ratios appropriate to the respective materials. Using the expressions, we evaluate their AMR ratios, where the expressions take into account the theoretical values of $\rho_{s\downarrow}/\rho_{s\uparrow}$ of the respective materials. The evaluated AMR ratios correspond well to the experimental results.

S1.00270 Molecular Dynamics Simulation of a Two Dimensional Heisenberg Fluid¹, B.V. COSTA, Universidade Federal de Minas Gerais, A.B. LIMA, E. CORREA, Universidade Federal do Triângulo Mineiro — In this work we use numerical Monte Carlo and Molecular Dynamics to study a classical two-dimensional compressible magnetic fluid. The magnetic interactions are realized through a Yukawa-like potential while particles interact through Lennard-Jones forces. Our preliminary results point to a very rich phase transition picture. At high density the system seems to undergo a magnetic transition, as suggested by the magnetization and susceptibility results.

¹Work was partially supported by CNPq and FAPEMIG.

S1.00271 ABSTRACT WITHDRAWN —

S1.00272 Ultrafast spin precession dynamics in exchange-biased FeNi/FeMn/FeNi films, JOO IN LEE, CHAN YONG HWANG, Korea Research Institute of Standards and Science — We investigated the spin precession dynamics in exchange-biased FeNi/FeMn/FeNi films by means of time-resolved magneto-optical Kerr effect (TR-MOKE). We observed the spin precession of all FeNi/FeMn/FeNi films in the TR-MOKE signals. The precession oscillations of the films changed rapidly as varying a thickness of antiferromagnet (FeMn). The period of the precession oscillations was not single and in the range of 10 to 20 ps. It is supposed that this is not only related to the exchange bias between ferromagnet and antiferromagnet but also double exchange biases in FeNi/FeMn/FeNi films.

S1.00273 Tilted polarizer devices with a generic spin torque efficiency coefficient¹, YA. B. BAZALIY, University of South Carolina, K.E. NEMCHENKO, Kharkiv University, Ukraine — Using the effective planar description [1-3] we study spin transfer devices with tilted polarizer. The dynamics of the free layer are investigated in the case of spin torque with substantially non-constant efficiency factor g . The switching diagram is constructed and discussed in qualitative terms.

S1.00274 Exchange coupled graded/soft/graded film with well-isolated grains fabricated by post-annealing, FANG WANG, University at Buffalo, Shanxi Normal University, JING ZHANG, JUN ZHANG, CHUNLING WANG, XIAOHONG XU, Shanxi Normal University — In order to solve the trilemma issue in perpendicular recording media, exchange spring and exchange coupled composite media have been proposed to reduce the coercivity of the hard magnetic layer without sacrificing the thermal stability. Thereafter, Suess proposed the graded media with a continuous variation in anisotropy to reduce the coercivity even further. Here we present an anisotropy-graded [FePt/C]5/Fe/[C/FePt]5 film, where C layer thickness gradually and symmetrically increases from two FePt ends to the soft Fe layer. In contrast with FePt/Fe bilayer, the graded/soft/graded film has a large reduction of 74% in coercivity. Adding C layers with different thickness not only tailors the Ku gradient, but also refines the grain size and weakens the intergranular exchange interaction. Micromagnetic simulation reveals that the magnetization reversal is initiated by domain wall formation at the center of the soft Fe layer followed by domain wall propagation in two FePt layers simultaneously. This work was supported by the National Science Foundation for Distinguished Young Scholars (Grant No. 51025101), NSFC (Grant No. 60776008, 51101095).

S1.00275 Anomalous magnetic anisotropy in Mn₃O₄ investigated by ⁵⁵Mn²⁺ and ⁵⁵Mn³⁺ Nuclear magnetic resonance, CHANGSOO KIM, JEONG HYUN SHIM¹, EUNA JO, SOONCHIL LEE, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea — Mn₃O₄ has Yafet-Kittel type spin structure below Neel Temperature (41K). The magnetization along the c-axis is smaller than that along the ab-plane even in external magnetic field of 30 Tesla, implying huge magnetic anisotropy in the ab-plane. We measured ⁵⁵Mn²⁺ and ⁵⁵Mn³⁺ Nuclear Magnetic Resonance (NMR) of a Mn₃O₄ single crystal in external magnetic field. The canting angles of Mn²⁺ and Mn³⁺ magnetic moments were calculated from the spectral shift obtained for various magnetic field directions between the a, b and c-axes. With the canting angle data, we estimated the anisotropy energies of the Mn²⁺ and Mn³⁺ magnetic moments and the exchange energy between them. The result also shows that Mn³⁺ spins in the Yafet-Kittel structure lie in the ab-plane contrary to the previous reports.

S1.00276 Magnetic property enhancement of modified nanocrystalline ZrCo₅-based magnets¹, WENYONG ZHANG, XINGZHONG LI, RALPH SKOMSKI, JEFF SHIELD, DAVID J SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE68588, NANOMAGNETICS AND MAGNETOELECTRONIC MATERIALS TEAM — The metastable ZrCo₅ compound may be a good candidate for the development of rare-earth-free high-performance hard magnetic materials because of its high magnetocrystalline anisotropy field. Melt spinning is a good approach to synthesize metastable phase because of its high quench rate. In this work, the effect of Zr and Fe addition on structure and magnetic properties of melt-spun nanocrystalline Zr_{1+x}Co₅(0–0.3) alloys has been investigated. All the samples consist of orthorhombic ZrCo₅ hard magnetic and Co/Zr₆Co₂₃ soft magnetic phases. Proper Zr addition causes nanostructure refinement and the increase of the hard magnetic phase content, which strengthens intergrain exchange coupling. As a result, coercivity and maximum energy product of ZrCo₅-based magnet are significantly enhanced. The best magnetic properties: $iH_c = 2.8$ kOe, $(BH)_{max} = 4$ MGOe, which is the best value among Co-Zr binary alloys, are achieved in Zr_{1.1}Co₅. The temperature coefficient of its coercivity between 10 and 380K is -0.05%/K. The saturation magnetization of nanocrystalline Zr_{1.1}Co₅ is greatly increased due to 16 at% Fe addition.

S1.00277 Competing magnetic interactions and interfacial frozen spin in Ni-NiO core-shell nano-rods¹, YUAN-CHIEH TSENG, HAO-CHUN HSU, CHIH-CHIEH LO, National Chiao Tung University, NATIONAL CHIAO TUNG UNIVERSITY TEAM — This work investigates the complex interfacial magnetism of free-standing Ni-NiO core-shell rods fabricated by electrodeless plating and an anodic aluminum oxide template. Vertical magnetization shift, arising from opposite field cooling conditions, suggests frozen spin (FS) at the Ni-NiO interface. The FS was related to the pinning effects of the NiO on the Ni, which mediated the interfacial antiferromagnetic (AFM)-ferromagnetic (FM) coupling, leading to the temperature-dependent properties of the rods. The FS was evident below 100 K, at which point the NiO-AFM dominated the properties with a suppressed coercive field and non-saturated magnetization. Above 100 K, however, the Ni-FM dominated and the FM phase was restored, due to the disappearance of the FS.

¹The work is supported by the National Science Council of Taiwan under Grant No. NSC 98-2112-M-009 022-MY3.

S1.00278 Magnetic Properties of Nanostructured Mn_xTaS₂, PAUL SHAND, ZACH GRIFFITH, STROH LESLIE, TIM KIDD, LAURA STRAUSS, University of Northern Iowa — We have fabricated tapelike nanostructures of Mn_xTaS₂ that consist of bundles of TaS₂ nanotubes intercalated with Mn. The magnetic properties of samples with Mn concentrations of 15% and 23% (nominal 25%) were investigated. The Mn_{0.23}TaS₂ sample exhibited ferromagnetic characteristics with a Curie temperature near 90 K, which is close to that of bulk Mn_{0.25}TaS₂ crystals; however, the behavior of the linear and nonlinear ac susceptibility in the vicinity of the transition indicates departures from standard 3D ferromagnetic behavior. The Mn_{0.15}TaS₂ sample exhibits a spin-glass-like transition near 8 K, with a frequency-dependent ac susceptibility near the transition and hysteretic and aging effects below the transition. The imaginary part of the ac susceptibility becomes non-zero at temperatures significantly higher than the transition temperature, which is unusual for spin glasses. Overall, our measurements indicate strong similarities between our nanostructured samples and their bulk crystalline counterparts but some intriguing differences as well. It is not yet clear whether these differences can be attributed to the quasi-one-dimensional nature of the nanostructured Mn_xTaS₂ samples.

S1.00279 The contactless measurement of forces which affect a magnetic particle in a fluid and its manipulation, SUSUMU TOKURA, MASAKAZU HARA, NORIHITO KAWAGUCHI, JUN IZAWA, Research Laboratory, IHI Corporation, NAOYUKI AMEMIYA, Department of Electrical Engineering, Kyoto University — The magnetic force has been used for the drug delivery, the cell/DNA manipulation, and other handlings of micro or nanoparticles. When magnetic particles are suspended in a fluid, they are influenced by the magnetic force caused by the magnetic field gradient, the gravity force, and the buoyance force. The magnetic torque also affects them to align their magnetic moments to the direction of the applied magnetic field. Furthermore, the viscous force or the force between the magnetized magnetic particles themselves cannot be neglected. In this study, methods of the quantitative measurement of these forces and the manipulation of a magnetic particle were developed. Four electromagnets were used to apply magnetic fields to ferrite particles (300nm-300 μ m) in a fluid in a vessel. The particle tracking velocimetry method was used to visualize the behavior of the particles. Based on the theory of the magnetic suspension and balance system, the vertical and horizontal forces affected a magnetic particle were estimated from the current in the coil of each electromagnet without any physical contact to it. And, the contactless manipulations of the magnetic particle suspended in the stagnated or flowing fluid by controlling the coil currents were demonstrated successfully.

S1.00280 Determination of second order phase transition temperature of monoclinic phase of $Gd_5(Si_xGe_{1-x})_4$, DAVID JILES, RAVI HADIMANI, Iowa State University, Y. MELIKHOV, Cardiff University, MAGNETIC RESEARCH GROUP TEAM, WOLFSON CENTRE FOR MAGNETICS TEAM — $Gd_5(Si_xGe_{1-x})_4$ has a first order phase transition from high temperature paramagnetic monoclinic to low temperature ferromagnetic orthorhombic phase for $0.4 < x < 0.51$. It is not possible to determine experimentally the second order phase transition temperature of orthorhombic or monoclinic phase. Previous studies have estimated second order phase transition temperature of the orthorhombic phase using a modified Arrott plot technique. The composition $0.3 < x < 0.4$ $Gd_5(Si_xGe_{1-x})_4$ has mixed monoclinic and orthorhombic phases without a clear transition between the two phases. We have determined the second order phase transition temperatures of both orthorhombic and monoclinic phases for $Gd_5Si_{1.5}Ge_{2.5}$ using modified Arrott plots. Magnetic moment vs. magnetic field for various temperatures was measured using a SQUID magnetometer. Arrott plots were plotted from $M^{1/\beta}$ and $(H/M)^{1/\gamma}$ isotherms using critical exponents of $1/\gamma = 0.85$ and $1/\beta = 1.85$. We obtained two sets of parallel lines for the orthorhombic phase and the monoclinic phase. The temperature of the isotherm that passes through the origin for both orthorhombic and monoclinic phase was estimated to be 299.5 K and 197 K respectively.

S1.00281 Boron diffusion due to annealing in CoFeB/MgO/CoFeB interfaces: A combined HAXPES and NEXAFS study, ABDUL RUMAIZ, NSLS, Brookhaven National Laboratory, CHERNO JAYE, JOSEPH WOICIK, NIST, WEIGANG WANG, Department of Physics, Johns Hopkins University, DANIEL FISCHER, NIST, C.L. CHIEN, Department of Physics, Johns Hopkins University — We report the hard x-ray photo-electron spectroscopy (HAXPES) and near edge x-ray absorption fine structure (NEXAFS) of CoFeB|MgO|CoFeB tunnel junctions as a function of annealing time. Upon annealing, the oxidation state of B changes from predominantly elemental (0 valence) boron in the as deposited sample to higher oxidation in annealed samples as evident from HAXPES spectra. The NEXAFS spectroscopy results showed that upon heating, B species migrate towards the MgO and interact with it. A comparison of the tunnel junction NEXAFS signature with some standards suggests that the B forms a 3-fold coordinated boron compound in the MgO environment and 4-fold coordinated boron resembling Kotoite mineral in the CoFe/MgO interface.

S1.00282 Mössbauer study of corrosion and abrasion products in oil transporting pipes, RAUL W. GOMEZ, JOSE LUIS PEREZ MAZARIEGO, VIVIANNE MARQUINA, MA. LUISA MARQUINA, ROSALIA RIDAURA, Facultad de Ciencias, UNAM, Mexico D.F. 04510, LORENZO MARTINEZ, ICF, UNAM, Cuernavaca, Mor. — It is known that one of the main technological problems in carbon steel oleoducts is the corrosion produced by different substances, such as water, carbon dioxide, sulfur, and microorganisms. In addition, if in such mixture there is sand, aggressive sludge can be form that abrasions material from the oleoduct. A room temperature Mössbauer study of corroded material taken from different sites of oleoducts is presented. Most of the Mössbauer spectra reveal the presence of nanoparticles, indicating that in these pipes the abrasion problem is severe. A preliminary identification of the oxidized samples suggests the presence of magnetite, and some Iron hydroxides. Further studies are in course in order to identify unambiguously the products present in the corroded materials.

S1.00283 STRONGLY CORRELATED SYSTEMS, INCLUDING QUANTUM FLUIDS AND SOLIDS —

S1.00284 Performance of hybrid density functional theory for α versus δ -Pu¹, SARAH C. HERNANDEZ, ASOK K. RAY, University of Texas at Arlington — Hybrid density functional theory, which replaces a fraction of density functional theory exchange with exact Hartree-Fock exchange, has been used to study the electronic, geometric, and magnetic properties of α -Pu and compared with our previous results for δ -Pu. A non-magnetic (NM) ground state was realized for $\alpha=0.55$ (α indicating the fraction of the HF exchange) for δ -Pu but the equilibrium atomic volume deviated from experiment by 19%, the 5f electron population was close to 4 and a 5f DOS that shows anomalous localization and failed to match experimentally obtained PES data.² For α -Pu, a NM ground state was obtained at 40% HF exchange. Comparing the two phases at the NM ground state, the 5f population is about the same, but energy differences between the different magnetic configurations for the two phases are observed. For δ -Pu NM-FM and NM-AFM ΔE are 86.33 and 82.28 mRy/atom, respectively, and for α -Pu the NM-FM and NM-AFM ΔE are 144.98 and 60.72 mRy/atom, respectively. The 5f DOS for δ -Pu show no DOS at the Fermi level but the presence of localized states, while for α -Pu DOS show delocalization. Though hybrid density functional theory might not perform better compared to DFT for δ -Pu, it shows promise for α -Pu.

S1.00285 Mott behavior of ultrathin epitaxial LaNiO₃ films and interfaces via hard x-ray and standing-wave excited photoemission, ALEXANDER GRAY, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, ALEXANDER KAISER, Department of Physics, University of California, Davis, JUNWOO SON, ANDERSON JANOTTI, Materials Department, University of California, Santa Barbara, SEE-HUN YANG, IBM Almaden Research Center, AARON BOSTWICK, Advanced Light Source, LBNL, SHIGENORI UEDA, KEISUKE KOBAYASHI, NIMS Beamline Station at SPring-8, CHRIS VAN DE WALLE, SUSANNE STEMMER, Materials Department, University of California, Santa Barbara, CHARLES FADLEY, Department of Physics, University of California, Davis — In this study we apply several emerging x-ray photoemission techniques to study Mott behavior of ultrathin LaNiO₃ films and interfaces in a depth-resolved manner. In order to understand the effects of thickness and strain on the electronic structure, we apply hard x-ray photoemission (HAXPES) at 6 keV to epitaxial LaNiO₃ films of varying thickness under compressive and tensile strain. Mott metal-to-insulator transition is observed for the thinnest films. Furthermore, standing-wave-excited photoemission is used to study the electronic structure of ultrathin LaNiO₃ in a SrTiO₃/LaNiO₃ superlattice. Standing-wave measurements of core-level and valence band spectra are used to derive layer-resolved densities of states, revealing a suppression of electronic states near the Fermi level in the multilayer as compared to bulk LaNiO₃. Further analysis shows that the suppression of these states is not homogeneously distributed over the LaNiO₃ layers but is more pronounced near the interfaces.

S1.00286 Depth-resolved ARPES of buried layers and interfaces via soft x-ray standing-wave excited photoemission, ALEXANDER GRAY, Stanford Institute for Materials and Energy Sciences, SLAC Linear Accelerator Laboratory, JAN MINAR, Physical Chemistry Institute, Ludwig Maximilian University, LUKASZ PLUCINSKI, Research Center Jülich, MARK HUIJBEN, University of Twente, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, LBNL, SEE-HUN YANG, IBM Almaden Research Center, CLAUS SCHNEIDER, Research Center Jülich, HUBERT EBERT, Physical Chemistry Institute, Ludwig Maximilian University, CHARLES FADLEY, Department of Physics, University of California Davis — We introduce a new depth-selective photoemission technique, achieved by combining soft x-ray ARPES with standing-wave (SW) excited photoelectron spectroscopy, wherein the intensity profile of the exciting x-ray radiation is tailored within the sample. This effect is accomplished by setting-up an x-ray standing-wave field within the sample by growing it on a synthetic periodic multilayer mirror substrate, which in first-order Bragg reflection acts as the standing-wave generator. The antinodes of the standing wave function as epicenters for photoemission and can be moved vertically through the buried layers and interfaces by scanning the x-ray incidence angle. The new SW-ARPES technique is then applied to the investigation of the electronic properties of the buried interface within a magnetic tunnel junction $\text{La}_{0.7}\text{Sr}_{0.3}\text{MnO}_3/\text{SrTiO}_3$. The experimental results are compared to the state-of-art one-step photoemission theory including matrix element effects.

S1.00287 Dependence of Polarization and Dielectric response on Epitaxial Strain in $(\text{Ba}_x\text{Sr}_{1-x})\text{TiO}_3$ Ultrathin Films from First-Principles, SAAD BIN-OMRAN, King Saud University — A first-principles-derived schemes is used to use a first-principles-derived technique to construct the temperature-versus-misfit strain phase diagrams for the whole BST composition rang (i.e., $x=0.00, 0.20, 0.40, 0.60, 0.80, 1.00$). Moreover, we investigate the dependence of their dielectric and ferroelectric properties on the strain and the concentration. Our results reveal that the predicated phase diagrams show a topology similar to those calculated by Shirokov et. al. *Phy. Rev. B.* **79** 144118 (2009) with quantitative discrepancies that will be revealed and explained. Our results also indicate that in-plane strain increases (respectively, decreases) the in-plane (respectively, out-of-plane) dielectric constants. Furthermore, the out-of-plane component of dielectric permittivity ϵ_{33} enhances with lowering x in $(\text{Ba}_x\text{Sr}_{1-x})\text{TiO}_3$ films. We hope that our results will be benefits to many scientists and will lead to new strategies for material design.

S1.00288 A first principles thermodynamic study of Si-HfO₂ and Pt-HfO₂ interfaces, HONG ZHU, RAMPI RAMPRASAD, University of Connecticut — Atomic-level control of dielectric-semiconductor and dielectric-metal interfaces has become critical in determining the properties of the emerging high- k oxide-based MOSFETs. Using Si-HfO₂ and Pt-HfO₂ as an example, we investigate the evolution of these interface structures and electronic properties as a function of processing conditions by combining density functional theory results and statistical thermodynamics. Firstly, using first principles thermodynamics (FPTs), we determine the phase diagrams of Si-HfO₂ and Pt-HfO₂ interfaces. The vibrational and configurational entropic contributions to the free energies of the condensed phases are explicitly included. We demonstrate that the predictions of the FPT approach are in quantitative agreement with experiments for the interfaces considered. Secondly, a parameter-free methodology to determine the work function shift (or effective work function, EWF) of metal when interfaced with oxide is developed. This strategy is combined with statistical thermodynamics to predict the most probable EWF at given processing condition. The favorable agreement between the computed and experimental EWFs under generally adopted conditions is indicative of the usefulness of such full first-principles property-processing relationship studies.

S1.00289 Spiral spin order induced ferroelectricity in various type-II multiferroics, JUNMING LIU, YUAN LIU, Nanjing University, Department of Physics — In the past decade, one of the milestones associated with multiferroicity researches has been the experimental and theoretical identification of spin orders induced ferroelectricity in various spin frustrated oxide materials. These specific orders include the noncollinear spiral spin order, collinear spin order of exchange striction, E -type antiferromagnetic (AFM) order of double-exchange nature, and so on. Both the cross-product type and dot-product type spin interactions may contribute to the ferroelectricity generation. In consequence, experimentally observable multiferroic phenomena can be complex and reflected in multifold dimensions. In this talk, we address the spiral spin order induced ferroelectricity in various multiferroics where the cross-product type spin interaction is believed to contribute to the ferroelectricity. A modulation of such spiral spin order by various approaches is investigated and in particular the complex spin interactions in RMnO_3 with magnetic and non-magnetic doping at the R-site and Mn site will be discussed. Hopefully this talk may allow additional facts to our comprehensive understanding of the multifold interactions which eventually have impact on the magnitude of ferroelectric polarization in those multiferroics.

S1.00290 Ultrafast Photoinduced Magnetic Phase Transition in Manganites, TIANQI LI, AARON PATZ, Ames Laboratory and Dept of Physics and Astro, Iowa State University, JIAQIANG YAN, THOMAS LOGRASSO, Department of Physics and Astronomy, Iowa State University, ILIAS PERAKIS, Department of Physics, University of Crete, Greece, JIGANG WANG, Ames Laboratory and Dept of Physics and Astro, Iowa State University — The process of manipulating collective spin ordering and inducing magnetic phase transitions in highly *non-equilibrium, non-thermal* states at *femtosecond* time scales has received much current interest. These ultrafast processes offer opportunities for significant improvement over modern magneto-optical recording and magnetic storage/logic devices. One prominent system for such femtosecond magnetism is the strongly correlated manganites, which are truly responsive near the phase boundary, exhibiting extreme sensitivity to external stimuli such as light, electric and magnetic fields. Here, using ultrafast two-color magnetic circular dichroism spectroscopy, we observed distinct fs spin dynamics and critical behaviors in the strongly correlated manganites. We will discuss the origin of the responses as well as present a thorough study on differently doped and thin film samples.

S1.00291 δ -doped SrTiO_3 heterostructure in high magnetic fields, SCOTT RIGGS, MINU KIM, Stanford University, CHRIS BELL, Stanford University, IAN FISHER, Stanford University, ROSS MACDONALD, National High Magnetic Field Lab, HAROLD HWANG, Stanford University — High mobility 0.1% δ -doped STO magneto-transport has been measured in high magnetic fields as a function of angle. The Nb:SrTiO₃ doping layer is 25 nm thick and sandwiched between insulating SrTiO₃ buffer and cap layers on an SrTiO₃ substrate, putting it well within the 2-dimensional limit. The system exhibits Shubnikov-de Haas oscillations over the entire angle range measured. The resulting interplay between multiple sub-bands as the system approaches the quantum limit will be discussed.

S1.00292 Magnetic order and structural phase transition in strained ultrathin $\text{SrRuO}_3/\text{SrTiO}_3$ superlattice¹, MINGQIANG GU, XIAOSHAN WU, Nanjing University, GUOPING ZHANG, Indiana State University — Strain is one of the key parameters to control the properties of functional materials in fabrication. With first-principles simulations, we find for the first time that $\text{SrRuO}_3/\text{SrTiO}_3$ superlattice undergoes robust phase transitions with the in-plane lattice strain ranging from -4.5% to 6%. In the high tensile strain region, the magnetic ordering among neighboring Ru ions changes from a ferromagnetic to an antiferromagnetic phase, together with a metal-to-Mott-insulator transition, a unique character in our superlattice which is absent in the bulk. On the other hand, in the low strain region, the suppression of the octahedra tilting was also observed. The driving force of the suppression of tilting was investigated and found to be the charge redistribution in the Sr-O plane. All of these are important to the strategy of controlling the structural, electronic and magnetic properties in Ru-based perovskite systems.

S1.00293 Unexpected high conductivity at emerging twin boundaries in LSMO thin films, BENJAMIN MARTINEZ, LUIS GARZON, LUIS PENA, REGINA GÁLGERAN, ZORICA KONSTANTINOVIC, ALBERTO POMAR, BERNAT BOZZO, FELIP SANDIUMENGE, LUIS BALCELLS, CARMEN OCAL, ICMAB-CSIC. Campus de Bellaterra, Bellaterra 08193. SPAIN, NANOSTRUCTURED MAGNETIC MATERIALS COLLABORATION, SCANNING FORCE MICROSCOPY COLLABORATION — Transport properties of high quality $\text{La}_{2/3}\text{Sr}_{1/3}\text{MnO}_3$ (LSMO) thin films are studied by using Conducting Scanning Force Microscopy (C-SFM) measurements. Current images were acquired in a non-invasive manner by using the contact operation mode at the lowest possible applied load needed. LSMO thin film surface consists of one unit cell steps separating atomically flat terraces, with a low surface roughness on the terraces reproducing the STO substrate morphology. The existence of twin boundaries within the film is evidenced by conducting scanning force microscopy data. I(V) characteristics curves obtained at specific surface points indicate an important enhancement of the electronic response at the twin boundaries locations as compared to that measured on the twin surface. The absolute values of the measured current for a given voltage may differ by up to nearly one order of magnitude depending on whether the tip contacts the location where the twin boundary emerges at the surface or it is placed on a region on top of one of the twin crystallites. The origin of this large difference is not clear yet, but preliminary analysis seems to indicate that an increase in the density of states (DOS) at the boundaries might have an important contribution.

S1.00294 The role of correlations on oxygen orbitals in late transition-metal oxides, BAYO LAU, HUNG T. DANG, EMANUEL GULL, ANDREW J. MILLIS, Department of Physics, Columbia University, NY, NY — We investigate the effect on transition-metal oxide physics of including interactions on the oxygen sites as well as on the transition-metal site using a generalization of the single-site Dynamical Mean Field method. On-site repulsive and Hund's interactions in the full Slater-Kanamori form are treated using a numerically exact continuous-time quantum Monte-Carlo solver. We determine the metal-insulator and magnetic phase diagrams as a function of charge-transfer tendency and interaction strengths. The results are compared directly to models with no oxygen correlations, yielding insights about the role of oxygen-specific correlations.

S1.00295 Dynamical mean-field embedding of the dual fermion dynamical cluster approach for strongly correlated systems, ZI YANG MENG, SANDEEP PATHAK, SHUXIANG YANG, HANNA TERLETSKA, JUANA MORENO, MARK JARRELL, Louisiana State University — We extend the recently developed dual fermion dynamical cluster approach with a further embedding of the dual fermion lattice into a larger, third length scale. The resulting approach is a complete multi-scale many-body technique for strongly correlated electron systems. It treats the short length scales explicitly by the dynamical cluster approach, intermediate length scales diagrammatically with the dual fermion technique, and the largest length scales approximately at a dynamical mean-field level. This technique iterated to self-consistency on all the three length scales. To illustrate the implementation and applicability of this method, we test it with the one and two dimensional Falicov-Kimball model. We will specifically address the convergence and critical scaling behavior of the charge-density-wave transition temperature.

S1.00296 Single domain VO_2 single crystals exhibiting metal-insulator transition and insulator-insulator transition, JOONSEOK YOON, Physics Dept., Yonsei Univ., BONGJIN MUN, Applied Physics Dept., Hanyang Univ., KAI CHEN, Advanced Light Source, LBNL & CAMP-Nano, Xi'an Jiaotong Univ., CATHERINE DEJOIE, NOBUMICHI TAMURA, MARTIN KUNZ, ZHI LIU, SUNG-KWAN MO, Advanced Light Source, LBNL, KYUNGSUN MOON, Physics Dept., Yonsei Univ., CHANGWOO PARK, Hanbat National Univ. & Advanced Nano Products, HONGLYOUL JU, Physics Dept., Yonsei Univ. — Electrical transport, optical microscopy, and synchrotron-based x-ray micro-diffraction measurements have been carried out on single domain VO_2 single crystals, exhibiting an abrupt first-order metal-insulator transition (MIT) with a high resistance ratio $\sim 10^5$ near $\sim 67^\circ\text{C}$ and a gradual insulator-insulator transition (IIT) at $\sim 48^\circ\text{C}$. Low temperature ($T < 45^\circ\text{C}$), intermediate ($\sim 50^\circ\text{C} < T < \sim 67^\circ\text{C}$), above MIT ($T > 67^\circ\text{C}$) phases were insulating monoclinic M2 with half vanadium ion dimerization, monoclinic M1 with full vanadium ion dimerization, and rutile (R) phases, respectively. In this poster, we will present unusual structural phases of M1, M2, and R of single-domain VO_2 single crystals and discuss the relationships between structures and the characteristics of the MIT of VO_2 .

S1.00297 Mechanism of orbital-selective phase transition by different magnetic states, HUNPYO LEE, YU-ZHONG ZHANG, HARALD O. JESCHKE, ROSER VALENTI, None — Using a dynamical cluster approximation we analyzed the behavior a degenerated two-orbital anisotropic Hubbard model at half-filling where both orbitals have equal bandwidths and one orbital is in paramagnetic (PM) state while the other one is in antiferromagnetic (AF) solution. We found an orbital-selective metal-insulator transition in which the PM orbital undergoes a transition from a Fermi liquid (FL) to a Mott insulator through a non-FL, while the AF orbital displays a transition from a FL to an AF insulator through an AF metallic phase. Finally, we would discuss that our intermediate phases are possibly related to the puzzling AF metallic state iron-pnictide superconductors.

S1.00298 Lattice-Symmetry-Driven Phase Competition in Vanadium Dioxide¹, ALEXANDER TSELEV, Oak Ridge National Laboratory, Oak Ridge, TN, USA, IGOR A. LUK'YANCHUK, University of Picardie Jules Verne, Amiens, France, ILIA N. IVANOV, JOHN D. BUDAI, JONATHAN Z. TISCHLER, Oak Ridge National Laboratory, Oak Ridge, TN, USA, EVGHENI STRELCOV, ANDREI KOLMAKOV, Southern Illinois University Carbondale, Carbondale, IL, USA, SERGEI V. KALININ, Oak Ridge National Laboratory, Oak Ridge, TN, USA — We performed group-theoretical analysis of the symmetry relationships between lattice structures of R, M1, M2, and T phases of vanadium dioxide in the frameworks of the general Ginzburg-Landau phase transition theory. The analysis leads to a conclusion that the competition between the lower-symmetry phases M1, M2, and T in the metal-insulator transition is pure symmetry driven, since all the three phases correspond to different directions of the same multi-component structural order parameter. Therefore, the lower-symmetry phases can be stabilized in respect to each other by small perturbations such as doping or stress.

S1.00299 Valence fluctuation driven quantum phase transition¹, PRAMOD KUMAR², N.S. VIDHYADHIRAJA³, Jawaharlal Nehru Centre for advanced Scientific Research (JNCASR), Bengaluru — In recent years quantum critical phenomenon have acquired a great interest in the condensed matter community. Many rare earth intermetallic compounds, which are also heavy fermions can be tuned easily to quantum critical point by application of external perturbations like magnetic field and pressure. YbRh_2Si_2 and CeCu_2Si_2 are a few examples. The periodic Anderson model (PAM) is a paradigm for studying these kind of systems. We investigate the extended periodic anderson model (EPAM), which includes Coulomb interaction of conduction and localised electrons using local moment approach (LMA) within dynamical mean field theory (DMFT) with the objective of developing an understanding of quantum phase transitions due to valence fluctuations. We show that tuning c-f interaction and on-site energy of localised electron (which can be achieved by varying external perturbation like pressure) leads to some exotic phenomena like vanishing of Fermi liquid scale. We study transport properties near quantum critical point and highlight the anomalies due to the proximity of QCP.

S1.00300 Band Insulators and Hubbard interactions, GUN SANG JEON, Department of Physics, Ewha Womans University, ARA GO, Department of Physics and Astronomy and Center for Theoretical Physics, Seoul National University — We investigate the theoretical models which are band insulators in the absence of interaction and evolve into Mott insulators under strong mutual repulsive interaction. We use the cellular dynamical mean-field theory to study the nature of the interaction-driven transitions in the systems. In various systems we compute the renormalized band gap which is defined by the self-energy corrected band gap and show that it is a convenient measure to characterize band insulating phases in such systems; the spectral gap is fully explained by the renormalized band gap when the systems remain in the band insulating phase. Finally we discuss interesting transition behavior from a band insulator to a Mott insulator.

S1.00301 Electronic structure of $\text{Lu}_{1-x}\text{La}_x\text{VO}_3$ single crystals using soft x-ray spectroscopy¹, BO CHEN, JUDE LAVEROCK, JAMES MCNULTY, DAVE NEWBY, KEVIN SMITH, Boston University, ANDERS GLANS, JINGHUA GUO, Advanced Light Source, GEETHA BALAKRISHNAN, RAVI SINGH, University of Warwick — The rare-earth vanadates, RVO_3 , offer a rich phase diagram of both orbital and spin ordering phenomena, stemming from their two-fold occupation of the three-fold degenerate V t_{2g} orbitals. It has been discussed that, in RVO_3 , which shows the t_{2g} orbital ordering, the Jahn-Teller coupling suppression is much weaker than that in the e_g electron systems. In order to address the orbital ordering effects, we report soft x-ray measurements of $\text{Lu}_{1-x}\text{La}_x\text{VO}_3$ single crystals, which approach both the smallest and largest rare-earth ionic sizes. X-ray absorption spectroscopy and x-ray emission spectroscopy, which reveal both the unoccupied and occupied partial density of states, are employed to observe the changes in the V $3d$ and O $2p$ states, across the orbital ordering transitions and R-site ionic radii. Also, resonant inelastic x-ray scattering is applied to probe the O $2p$ -V $3d^*$ charge transfer excitations and V $3d$ - $3d^*$ transitions. Together, these complementary techniques provide a picture of the electronic structure of $\text{Lu}_{1-x}\text{La}_x\text{VO}_3$ to test the role of the orbital ordering during phase transitions with varying rare-earth ionic sizes.

S1.00302 Singularity in self-energy and composite fermion excitations of interacting electrons¹, JIAN-XIN ZHU, LIJUN ZHU, Los Alamos National Laboratory — We propose that a composite fermion operator $f_{i\sigma}(2n_{i\bar{\sigma}} - 1)$ could have coherent excitations, where $f_{i\sigma}$ is the fermion operator for interacting electrons and $n_{i\bar{\sigma}}$ is the number operator of the opposite spin. In the two-impurity Anderson model, it is found that the excitation of this composite fermion has a pseudogap in the Kondo regime, and has a finite spectral weight in the regime where the excitation of the regular fermion $f_{i\sigma}$ has a pseudogap. In the latter regime, the self-energy of $f_{i\sigma}$ is found to be singular near Fermi energy. We argue that this composite fermion could develop a Fermi surface with Fermi liquid behaviors but "hidden" from charge excitations in lattice generalizations. We further illustrate that this type of excitations is essential in addressing the pseudogap state and unconventional superconductivity.

¹This work was supported by the National Nuclear Security Administration of the U.S. DOE at LANL under Contract No. DE-AC52-06NA25396, the U.S. DOE Office of Basic Energy Sciences, the LANL LDRD Program, and the DOE CINT at LANL.

S1.00303 Finite pulse relaxation calorimetry and specific heat of $\text{NdOs}_4\text{Sb}_{12}$ ¹, B. SOMSANUK, U.I. URBINA, P.-C. HO, Physics/California State University, Fresno, M.B. MAPLE, Physics/University of California, San Diego, T. YANAGISAWA, Hokkaido University, Japan — The compound $\text{NdOs}_4\text{Sb}_{12}$ is a mean-field ferromagnet at about 1 K. As inferred from specific heat measurements below 10 K, the electronic specific heat coefficient of this compound is very large (~ 520 mJ/mol-K²). Intriguingly, a recent ultrasonic measurement shows that this compound has double ultrasonic dispersions at ~ 15 K and 40 K. We have used our newly developed relaxation calorimeter to measure the specific heat of $\text{NdOs}_4\text{Sb}_{12}$ in the temperature range 11 K to 300 K. In this presentation, we will describe the experimental setup used for the finite pulse relaxation calorimetry in a cryocooler and the results of our measurements on the $\text{NdOs}_4\text{Sb}_{12}$ sample.

S1.00304 Magnetization measurements in site disordered UCu_4Ni ¹, ARIANA VALDEZ, E. SOTO, O.O. BERNAL, Department of Physics and Astronomy, California State University, Los Angeles, CA 90032, D.E. MACLAUGHLIN, Department of Physics and Astronomy, University of California, Riverside, CA 92125, G.R. STEWART, J.S. KIM, Department of Physics, University of Florida, Gainesville, FL 32611 — UCu_4Ni is a non-Fermi liquid, quantum critical system, obtained from dilution of Cu for Ni in antiferromagnetic (AFM) UCu_5 . Introduction of Ni in the lattice structure of the parent compound suppresses the AFM transition temperature from 16.5 Kelvin down to zero at $x = 1$. Because Ni ions are slightly smaller than Cu ones (Pd and Cu ions are similar in size), Ni can be expected to distribute itself randomly between the two available crystal sites. UCu_4Ni is therefore a site-disordered material. We present a magnetization study of a random powder of UCu_4Ni as a function of applied magnetic field (-9.0 – 9.0 T) and temperature (2–300 K). We analyze the data from the point of view of magnetic disorder, as would be produced by a distribution of local magnetic susceptibilities, within the context of the Kondo Disorder Model. Comparison with similar existing studies in polycrystalline samples by others will be discussed.

S1.00305 Finite Size Effects on Electrical Transport of Nanoribbons of the Charge Density Wave Conductor NbSe_3 ¹, ADAM STABILE, Department of Physics, SUNY at Buffalo, LUISA WHITTAKER, Department of Chemistry, SUNY at Buffalo, TAI-LUNG WU, Department of Physics, SUNY at Buffalo, PETER MARLEY, Department of Chemistry, SUNY at Buffalo, ZHENZHONG SHI, Department of Physics, SUNY at Buffalo, SARBAJIT BANERJEE, Department of Chemistry, SUNY at Buffalo, G. SAMBANDAMURTHY, Department of Physics, SUNY at Buffalo — NbSe_3 is a textbook example of a charge density wave material, and although its properties are well known in bulk, its nanoscale characteristics are relatively unexplored. In particular, owing to the chain-like atomic structure of NbSe_3 , electric transport studies on quasi-one-dimensional devices remain a new frontier in scientific research in which unique finite size effects occur as a result of geometrical confinement and lattice reconstruction in the nanoscale. We used a novel, facile chemical vapor transport method for synthesizing nanoscale, single-crystalline NbSe_3 nanoribbons. This bottom-up method for preparing free-standing nanoribbon devices avoids potential sample degradation observed in top-down approaches. Typical ribbons have cross sectional area 10^4 nm² or less and lengths 10 – 50 μm . Single nanoribbon electrical transport measurements show expected charge density wave transitions at 59 and 141 K. We also observe significant enhancement in the depinning effect and sliding regimes mainly attributed to finite size effects.

S1.00306 The magnetoelectric effect on the novel multiferroic Co_3TeO_6 , C.C. CHOU, S. MUKHERJEE, J.H. ZHANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, J.L. HER, Division of Natural Science, Center for General Education, Chang Gung University, Tao-Yuan 333, Taiwan, H. BERGER, Institutes of Physics of Complex Matter, Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland, H.D. YANG, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — The magnetic, thermal, and dielectric measurements were performed on a single crystal sample Co_3TeO_6 . Two anomalies are observed at $T_1 \sim 26$ K and $T_2 \sim 18$ K in magnetic susceptibility and specific heat measurements. Dielectric constant data show a step anomaly at 18 K, which does not display frequency-dependent behavior but a magnetoelectric effect. Furthermore, the values of the magnetoelectric coupling constant γ were calculated, which are 0.0268 and 0.0239 at 7 K and 13 K, respectively. The temperature-dependent X-ray diffraction suggests that the lattice parameters slightly deviate from linear trend as temperature down to 26 K, and then shows an anomalous variation around 18 K, where a structural distortion probably appears. All phenomena of our results indicate that Co_3TeO_6 is one member of multiferroic materials

S1.00307 Quantum phase transition of the sub-Ohmic rotor model, MANAL AL-ALI, THOMAS VOJTA, Missouri University of Science and Technology — We investigate the behavior of an N -component quantum rotor coupled to a bosonic dissipative bath having a sub-Ohmic spectral density $J(\omega) \propto \omega^s$ with $s < 1$. With increasing dissipation strength, this system undergoes a quantum phase transition from a delocalized phase to a localized phase. We determine the exact critical behavior of this transition in the large- N limit. For $1 > s > 1/2$, we find nontrivial critical behavior corresponding to an interacting renormalization group fixed point while we find mean-field behavior for $s < 1/2$. The results agree with those of the corresponding long-range interacting classical model. The quantum-to-classical mapping is therefore valid for the sub-Ohmic rotor model.

S1.00308 Pomeranchuk instability from a black hole¹, KA WAI LO, University of Illinois at Urbana Champaign, MO-HAMMAD EDALATI, University of Texas at Austin, PHILIP PHILLIPS, University of Illinois at Urbana Champaign — Within the AdS/CFT correspondence, we introduce a probe spinor field and a neutral symmetric traceless spin-two field which are dual to a fermionic operator and a neutral tensor order parameter in the boundary field theory. By considering a certain coupling between the two probe fields, we show that a transition induced by condensation of the neutral order parameter dual to the neutral spin-two field can lead to the breaking of rotational symmetry of Fermi surface and hence a Pomeranchuk instability. The critical properties of this transition are computed.

S1.00309 Superfluidity Without Boson Condensation, A.M. KADIN, Princeton Junction, NJ — Superfluidity is generally attributed to condensation of boson wavefunctions. He-4 atoms have zero net spin in the nucleus and in the electrons, and so are bosons, while He-3 atoms have a nuclear spin of $1/2$, and are fermions. This fits the conventional understanding that the superfluid transition of He-4 at 2.2 K is due to boson condensation, while the lack of such a transition in He-3 is due to the absence of bosons until atomic pairing into boson-like Cooper pairs occurs in the mK range. However, Kadin [1] has extended a novel non-boson superconducting condensation mechanism to superfluids. This is based on an interleaved two-phase structure of close-packed electron orbitals (analogous to an ionic liquid), whereby each orbital is surrounded by multiple anti-phase orbitals, with nodes between them to maintain orthogonality. This entire structure moves together as a superfluid, preserving long-range phase coherence. The lack of superfluidity in He-3 is attributable *not* to these atoms being fermions, but rather to the presence of unpaired nuclear spins that destroy the phase coherence due to spin-flip scattering. This is consistent with the behavior of mixtures of He-3 and He-4. Only at mK temperatures, when the nuclear spins order and spin-flip scattering is suppressed, is superfluidity again possible. A similar picture may also be extended to “Bose-Einstein condensates” in dilute concentrations of alkali metal atoms, but *only* if one assumes the presence of close-packed atomic clusters or droplets, rather than a dilute gas. [1] A.M. Kadin, <http://arxiv.org/abs/0909.2901> (2009); <http://arxiv.org/abs/1107.5794> (2011).

S1.00310 ^3He - ^4He liquid mixtures investigated by neutron imaging technique at low temperatures¹, PATRICK GUMANN, University of Waterloo, JULIA SCHERSCHLIGT, DANIEL HUSSEY, DAVID JACOBSON, NIST Center for Neutron Research, DAVID CORY, IVAR TAMINIAU, University of Waterloo — Helium is a unique element which exhibits a variety of different phases and unusual behaviors. It can be found in nature in two stable isotopic forms: ^3He and ^4He . One of the most profound quantum mechanical effects, superfluidity, occurs below 2.17 K in liquid helium ^4He and 0.003 K in liquid ^3He . There are also interesting phenomena occurring in mixtures of the two isotopes. One demonstrative example is the finite solubility of liquid ^3He (a Fermi system) in superfluid ^4He (a Bose system) even at $T = 0$ K. This is the basic principle in the operation of a ^3He - ^4He dilution refrigerator capable of continuously producing 2 mK. While much has been done in studies of the thermodynamical, quantum properties of liquid helium mixtures, there has not been any attempt to visualize the dynamics of ^3He in liquid ^4He . Presented results of neutron imaging experiments on 0.3 bar liquid ^3He - ^4He mixtures, at 1.5 K have shown a clear diffusion of ^3He driven by the difference in chemical potential. The data were taken for over 12 hours using a high resolution CCD camera.

S1.00311 Traces of Vortices in Superfluid Helium Droplets¹, LUIS F. GOMEZ, Department of Chemistry, University of Southern California, Los Angeles, CA, EVGENY LOGINOV, SICPA SA, Prilly, Switzerland, ANDREY F. VILESOV, Department of Chemistry and Department of Physics, University of Southern California, Los Angeles, CA — We report on the observation of vortices in superfluid ^4He droplets produced by a free fluid-jet expansion. The vortices were traced by introducing silver atoms into the droplets, which clustered along the vortex lines. The silver clusters were subsequently surface deposited and imaged via electron microscopy. The prevalence of elongated track-shaped deposits shows that vortices are ubiquitous in droplets larger than about 300 nm and that their lifetime exceeds a few milliseconds. In these experiments the droplets become superfluid within a few microseconds, which is at least 10^6 times faster than in previous bulk helium experiments. We discuss possible formation mechanisms and the stability of the vortices obtained during this rapid phase transition.

S1.00312 POST-DEADLINE ABSTRACTS —

S1.00313 Size effect of properties in hybrid of gold nanoparticles and calamitic mesogen¹, CHIH-HAO YU, CHRIS WELCH, BAI J. TANG, CHRISTOPHER J. SCHUBERT, GEORG H. MEHL, Department of Chemistry, University of Hull — In this contribution we describe the synthesis and investigation of Au NPs functionalized with organic mesogenic groups which self-assemble into liquid crystalline phases. A nematic mesogenic liquid crystalline laterally reacts with functionalized gold via a siloxane group using Karstedt's catalyst. Compared to earlier work where NPs were in the size of 1.5-2.5 nm, we report here on larger than 5 nm sized particles. The synthesis of the particles is based on a new methodology using digestive ripening and synthesis functionalisation of the organic groups. This example may open up a protocol for liquid crystal molecules encapsulated in nanoparticles. Properties of the calamitic mesogen encapsulated gold nanoparticles have been investigated by HRTEM, NMR, UV/Vis, differential scanning calorimetry (DSC), optical polarizing microscopy (OPM).

S1.00314 Trimeric surfactant as superior boundary lubricant, NIR KAMPF, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel, CHUNXIAN WU, YILIN WANG, Key Laboratory of Colloid and Interface Science, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China, JACOB KLEIN, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel — Surfactants are widely used to modify surfaces and interfaces properties. A unique cationic trimeric surfactant, tri(dodecyltrimethylammonioacetox)-diethyltri-amine trichloride (DTAD), was found to form liposome-like aggregates in solution or a highly ordered bilayer patterns on mica surface [1,2]. We have investigated the normal and shear forces between two atomically smooth mica surfaces across this surfactant using the surface force balance (SFB) technique. Shear forces measured across the trimeric surfactant solution demonstrate ultra-low friction coefficient ($\mu=5 \times 10^{-5}$) under pressure of tens of atmospheres. AFM scans under the trimeric surfactant solution demonstrate the presence of large spheres (ca. 100nm in diameter) on the mica. The contribution of the compressed charged spheres to the ultra-low friction measured can be explained by the efficient hydration lubrication mechanism exist between the hydrated surfactant head-groups and the mica surface. A weak dependence of the friction coefficient to the shear rate or amplitude was observed.

S1.00315 Freely Suspended Smectic Films in Aqueous Environment, KARTHIK PEDDIREDDY, CHRISTIAN BAHAR, Max Planck Institute for Dynamics and Self Organization — Smectic liquid crystals easily form thin films which are freely suspended on a solid frame in air. These systems have been thoroughly studied for various purposes such as structural studies of smectic phases, investigating phase transitions in two-dimensional systems, and studying various physical properties of liquid crystals. In the present study, we explore the preparation of freely suspended smectic films in water. A prerequisite is the presence of a surfactant which accumulates at the liquid-crystal/water interface and induces a homeotropic anchoring of the director, so that the smectic layers align parallel to the two film surfaces. The presence of the surfactant might also serve as a handle to tune properties such as the surface tension of the films (which is hardly possible for freely suspended films in air). We study the formation of films in water using different frames and different surfactants, and we focus especially on the thinning behaviour which occurs when the temperature is increased towards the smectic - nematic or smectic - isotropic transition.

S1.00316 Stiffness Dependent Separation of Cells in a Microfluidic Device, TODD SULCHEK, GONGHAO WANG, WENBIN MAO, CAITLIN HENEGAR, ALEXANDER ALEXEEV, Georgia Tech — Abnormal cell mechanical stiffness can point to the development of various diseases including cancers and infections. We report a new high-throughput technique for continuous cell separation utilizing variation in cell stiffness. We use a microfluidic channel decorated by periodic diagonal ridges to separate K562 lymphoblastic cell line modified to different mechanical stiffness values. Diagonal ridges within the microfluidic flow channel compress and deform the cells in rapid succession to translate each cell perpendicular to the channel axis in proportion to its stiffness. Atomic force microscopy (AFM) was used to directly measure the Young's modulus of modified K562 cells to verify the stiffness variation. We demonstrate that soft cells can be separated from stiff cells at physiological concentrations with a fivefold enrichment of cell populations. This microfluidic device opens the way for conducting rapid and low-cost cell analysis and purification through physical markers.

S1.00317 Spin-orbital models using dipolar fermions in zig-zag optical lattices¹, TEIMURAZ VEKUA, GAOYOUNG SUN, GEORGE JACKELI, LUIS SANTOS, none — Ultra-cold dipolar spinor fermions in zig-zag type optical lattices can mimic spin-orbital models relevant in solid-state systems, as pyroxene titanium and layered vanadium oxides, with the interesting advantage of reviving the quantum nature of orbital fluctuations. We discuss two different physical systems in which these models may be simulated, showing that the interplay between lattice geometry and spin and orbital quantum dynamics produces a wealth of novel quantum phases.

S1.00318 Spin-dependent low-energy ⁴He⁺ ion scattering on non-magnetic surfaces¹, TAKU SUZUKI, YASUSHI YAMAUCHI, SYUNICHI HISHITA, National Institute for Materials Science — We investigated electron-spin-polarized ⁴He⁺ ion scattering on various non-magnetic surfaces at kinetic energies below 2 keV [1]. It was observed that the scattered He⁺ ion yield depends on the He⁺ ion spin. We interpret this spin-dependent scattering in terms of the spin-orbit coupling (SOC) that acts transiently on the He⁺1s electron spin in the He⁺-target binary collision. This interpretation qualitatively explains the relationship between the spin-dependent scattering and the scattering geometry, incident velocity, and magnetic field arrangement. This is the first study to report SOC caused by projectile electron spin in ion scattering.

S1.00319 Iron chalcogenide photovoltaic absorbers – problems and opportunities, ROBERT KOKENYESI¹, VORRANUTCH JIERATUM, EMMELINE ALTSCHUL, DOUGLAS KESZLER, Department of Chemistry, Oregon State University, Corvallis, OR, RAM RAVICHANDRAN, BRIAN PELATT, JOHN WAGER, School of EECS, Oregon State University, Corvallis, OR, LIPING YU, STEPHAN LANY, National Renewable Energy Laboratory, Golden, CO, ALEX ZUNGER, University of Colorado at Boulder, Boulder, CO, CENTER FOR INVERSE DESIGN, EFRC COLLABORATION — Realizing new, efficient solar absorbers containing earth-abundant materials represents a critical element for expanding the reach of photovoltaic (PV) technologies, meeting growing energy needs. The use of Fe in PV was proposed more than 25 years ago in the form of FeS₂ pyrite. We report a concerted and integrated theoretical and experimental study that provides new insight into the problem of FeS₂. Computational results on FeS₂ reveal high formation energies for bulk point defects and small formation energies for S vacancies near the surface. These findings are consistent with the formation of metallic S-deficient binary Fe-S phases at low temperatures that affect the electrical and optical properties of thin films. We have used this new understanding to propose and implement design rules for identifying new Fe-containing materials—Fe₂SiS₄ and Fe₂GeS₄—that may circumvent the limitations of pyrite. These ternary materials are *p*-type with direct allowed optical band gaps near 1.5 eV.

S1.00320 Normal force and interpenetration between polyelectrolyte brushes¹, MARK MATSEN, University of Reading — We examine the normal force between two opposing polyelectrolyte brushes and the interpenetration of their chains that is responsible for sliding friction. We focus on the special case of semi-dilute brushes in a theta solvent, for which the classical strong-stretching theory (SST) can be solved analytically. Interestingly, SST predicts that the brushes contract as they are compressed together maintaining a polymer-free gap, which provides an explanation for the ultra-low frictional forces observed in experiment. We examine the degree to which the SST predictions are affected by chain fluctuations by employing self-consistent field theory (SCFT). While the normal force is relatively unaffected, fluctuations are found to have a strong impact on brush interpenetration. Even still, the contraction of the brushes does significantly prolong the onset of interpenetration, implying that a sizeable normal force can be achieved before the sliding friction becomes significant.

S1.00321 Optical Properties of III-V Semiconductors in Wurtzite Phase, AMRIT DE, University of California - Riverside, CRAIG PRYOR, University of Iowa — A number of recent experiments have shown that the photoluminescence intensity in free standing nanowires is polarization dependent. One contribution to this effect is the optical anisotropy arising from the tendency of the nanowires to crystallize in wurtzite form. We calculate the frequency dependent dielectric functions for nine non-Nitride wurtzite phase III-V semiconductors (AlP, AlAs, AlSb, GaP, GaAs, GaSb, InP, InAs and InSb), based on our maximally constrained empirical pseudopotential bulk band structure calculations. Their complex dielectric functions are calculated in the dipole approximation for polarization perpendicular and parallel to the c-axis of the crystal. We also predict their reflectivity spectra and the static dielectric constants. Optical selection rules are used to explain key features of the dielectric functions. In general it is seen that the III-V wurtzite phase semiconductors exhibit strong optical anisotropy which suggests that they could be potentially useful as nonlinear optical crystals.

S1.00322 Studies to Enhance Superconductivity in Thin Film Carbon, BENJAMIN PIERCE, LYLE BRUNKE, JACK BURKE, DAVID VIER, ANDREW STECKL, TIMOTHY HAUGAN, None, WPAFB/AFRL COLLABORATION, UNIVERSITY OF CINCINNATI COLLABORATION, UNIVERSITY OF CALIFORNIA SAN DIEGO COLLABORATION — With research in the area of superconductivity growing, it is no surprise that new efforts are being made to induce superconductivity or increase transition temperatures (T_c) in carbon given its many allotropic forms. Promising results have been published for boron doping in diamond films, and phosphorus doping in highly oriented pyrolytic graphite (HOPG) films show hints of superconductivity. Following these examples in the literature, we have begun studies to explore superconductivity in thin film carbon samples doped with different elements. Carbon thin films are prepared by pulsed laser deposition (PLD) on amorphous SiO_2/Si and single-crystal substrates. Doping is achieved by depositing from $(\text{C}_{1-x}\text{M}_x)$ single-targets with $\text{M} = \text{B}_4\text{C}$ and BN , and also by ion implantation into pure-carbon films. Previous research had indicated that Boron in HOPG did not elicit superconducting properties, but we aim to explore that also in thin film carbon and see if there needs to be a higher doping in the sample if trends were able to be seen in diamond films. Higher onset temperatures, T_c , and current densities, J_c , are hoped to be achieved with doping of the thin film carbon with different elements.

S1.00323 Anomalous resistivity peak in a ferromagnetic nanowire proximity-coupled to superconducting electrodes¹, SO TAKEI, VICTOR GALITSKI, University of Maryland — Motivated by the recent experiment of Wang et al. [Nature Physics 6, 389 (2010)], we study temperature-dependent transport in such a mesoscopic structure consisting of a ferromagnetic nanowire proximity-coupled to two conventional superconducting electrodes. It is assumed that the asymmetry in the tunneling barrier gives rise to the Rashba spin-orbit-coupling in the barrier that enables induced p-wave superconductivity in the ferromagnet to exist. First, we develop a microscopic theory of Andreev scattering at the spin-orbit-coupled interface, derive a set of self-consistent boundary conditions, and find an expression for the p-wave minigap in terms of the microscopic parameters of the contact. Second, we study temperature-dependence of the resistance near the superconducting transition and find that it should generally feature a fluctuation-induced peak. The upturn in resistance is related to the suppression of the single-particle density of states due to the formation of fluctuating pairs, whose tunneling is suppressed. We find a good agreement between the data and our fluctuation theory. Then, we discuss this and related setups involving ferromagnetic nanowires in the context of one-dimensional topological superconductors.

S1.00324 ABSTRACT MOVED TO W21.00007 —

S1.00325 Soft phonon mode and superconducting properties of 2H-NbS₂ compared to 2H-NbSe₂, MAXIME LEROUX, CNRS / UJF, Institut NÉEL, 38042 Grenoble cedex 9, France, MATHIEU LE TACON, Max Planck Institut für Festkörperforschung, D-70569 Stuttgart, Germany, MATTEO CALANDRA, CNRS / IMPMC Université Paris 6, 75252, Paris cedex 05, France, THIERRY KLEIN, CNRS / UJF, Institut NÉEL, 38042 Grenoble cedex 9, France, LAURENT CARIO, CNRS / IMN Jean-Rouxel, Université de Nantes, 44322 Nantes, France, PIERRE RODIÈRE, CNRS / UJF, Institut NÉEL, 38042 Grenoble cedex 9, France — I will report on several recent results on 2H-NbS₂. This compound is the only superconducting 2H-dichalcogenide which does not develop a charge density wave (CDW). I will start with the temperature dependence of the phonon spectra of 2H-NbS₂ measured by Inelastic X-ray Scattering (IXS). Along ΓM , a huge softening of two phonon modes was observed on a wide part of the Brillouin zone. This is almost the same as the CDW precursor soft phonons modes that appear above $T_{CDW} \approx 33\text{ K}$ in 2H-NbSe₂[Weber11]. It clearly indicates that 2H-NbS₂ is also at proximity of a CDW instability. In the second part I will show measurement of H_{c1} and magnetic penetration depth, which show signs of a small energy scale in the superconducting gap of 2H-NbS₂, very similar to 2H-NbSe₂ [Fletcher07], and also in good agreement with STS measurement[Guillamon08]. In view of these two facts and as an open question, we would like to discuss the hypothesis of a quantum critical point (QCP) lying between 2H-NbS₂ and 2H-NbSe₂, where the 2nd order phase transition would be the CDW instability.

S1.00326 Evidence for a hidden-order pseudogap in URu₂Si₂¹, J.T. HARALDSEN, Los Alamos National Laboratory, Y. DUBI, Tel Aviv University, N.J. CURRO, University of California - Davis, A.V. BALATSKY, Los Alamos National Laboratory — Through an analysis and modeling of data from various experimental techniques, we present evidence for the presence of a hidden order pseudogap in URu₂Si₂ in the temperature range between 25 K and 17.5 K. Considering fluctuations of the hidden order energy gap at the transition as the origin of the pseudogap, we evaluate the effects that gap fluctuations would produce on observables like tunneling conductance, neutron scattering, and nuclear resonance, and relate them to the experimental findings. We show that the transition into hidden order phase is likely second order and is preceded by the onset of non-coherent hidden order fluctuations.

¹Work was carried out under the help and support of the National Nuclear Security Administration of the U.S. Department of Energy at Los Alamos National Laboratory under Contract No. DE-AC52-06NA25396 and the Center for Integrated Nanotechnology.

S1.00327 In Situ Electronic Characterization of Graphene Nanoconstrictions Fabricated in a Transmission Electron Microscope¹, YE LU, CHRISTOPHER MERCHANT, MARIJA DRNDIC, A.T. CHARLIE JOHNSON, University of Pennsylvania, UNIVERSITY OF PENNSYLVANIA TEAM — We report electronic measurements on high quality graphene nanoconstrictions (GNCs) fabricated in a transmission electron microscope (TEM), and the first measurements on GNC conductance with an accurate measurement of constriction width down to 1 nm. To create the GNCs, freely suspended graphene ribbons were fabricated using few-layer graphene grown by chemical vapor deposition. The ribbons were loaded into the TEM, and a current-annealing procedure was used to clean the material and improve its electronic characteristics. The TEM beam was then used to sculpt GNCs to a series of desired widths in the range 1-700 nm; after each sculpting step, the sample was imaged by TEM and its electronic properties were measured in situ. GNC conductance was found to be remarkably high, comparable to that of exfoliated graphene samples of similar size. The GNC conductance varied with width approximately as $G(w) = (e^2/h)w^{0.75}$, where w is the constriction width in nanometers. GNCs support current densities greater than $120 \mu\text{A}/\text{nm}^2$, 2 orders of magnitude higher than that which has been previously reported for graphene nanoribbons and 2000 times higher than that reported for copper.

¹National Science Foundation through Grant #DMR-0805136 (Y.L. and A.T.C.J.) and NIH Grant R21HG004767 and R21HG 557611 (C.M. and M.D.).

S1.00328 One-dimensional Si nanolines in hydrogenated Si(001), BIANCO FRANÇOIS, SIGRUN A. KÖSTER, JAMES G. H. OWEN, CHRISTOPH RENNER, University of Geneva, DPMC - MaNEP Quai Ernest-Ansermet 24, 1211 Geneva 4, DAVID R. BOWLER, University College London, London Centre of Nanotechnology — We present a detailed study of the structural and electronic properties of a self-assembled silicon nanoline embedded in the H-terminated silicon (001) surface, known as the Haiku stripe. The nanoline is a perfectly straight and defect free endotaxial structure of huge aspect ratio; it can grow micrometre long at a constant width of exactly four Si dimers (1.54 nm). Another remarkable property is its capacity to be exposed to air without suffering any degradation. The nanoline grows independently of any step edges at tunable densities, from isolated nanolines to a dense array of nanolines. In addition to these unique structural characteristics, scanning tunnelling microscopy and density functional theory reveal a one-dimensional state confined along the Haiku core. This nanoline is a promising candidate for the long sought after electronic solid-state one-dimensional model system to explore the fascinating quantum properties emerging in such reduced dimensionality. Phys. Rev. B, 84, 035328 (2011)

S1.00329 Formation of complex emulsion in microfluidic channel, CHANG-HYUNG CHOI, JONGMIN KIM, CHANG-SOO LEE, Chungnam National University — We first report a novel emulsification method using two binary mixtures that produces complex emulsion by phase separation, triggered by external diffusion of separation agent dissolved in continuous phase. A disperse phase consists of monomer and D-solvent (good solvent for disperse phase), while mixture of separation-triggering agent (SA) and C-solvent (good solvent for continuous phase) is used as a continuous phase. Individual droplet was formed by microfluidic system, allowing how the separation dynamically occurs as a function of time. This system consists of the three major steps involving the transformation of a single droplet into the complex emulsion. In the first, when two immiscible phases meet at cross-junction, droplets are generated and dispersed in continuous phase containing the SA. Since the SA is only selectively soluble in the monomer of disperse phase, external diffusion of SA into the droplets through the interface occurs which initiates phase separation. In transient state, the external diffusion of the SA generates both partial separated region and SA/monomer complex at the near interface of partial separated region. In the last step, where the phase separation fully occurs, single droplets transform into complex emulsion such as double emulsion or multiple emulsion with high order. In addition, we demonstrate a capability for generation of complex emulsions gives a great opportunity to fabricate functional materials using template synthesis.

S1.00330 Heralded entanglement between two single atoms at remote locations, MARKUS WEBER, JULIAN HOFMANN, WENJAMIN ROSENFELD, LMU Munich and Max Planck Institute of Quantum Optics, Germany, CHRISTIAN KURTSTIEFER, University of Singapore, NORBERT ORTEGEL, MICHAEL KRUG, HARALD WEINFURTER, LMU Munich and Max Planck Institute of Quantum Optics, Germany — Entanglement between single trapped atoms at large distances is a key resource for future applications in quantum communication, like quantum networks and the quantum repeater. We have set up two independently operating atomic traps situated in two neighboring laboratories separated by 20 meter. On each side we capture a single Rb-87 atom in an optical dipole trap and generate a spin-entangled state between the atom and a single spontaneously emitted photon [1]. These photons are collected with high-NA objectives, coupled into single-mode optical fibers, and guided to the same fiber beam splitter (BS) where they interfere. A coincident detection of two orthogonally polarized photons leaving the BS allows us to project them onto two out of four maximally entangled Bell states. This Bell-state-projection on the photons swaps the entanglement onto the atoms. Here we report the faithful generation and analysis of entanglement between two single trapped atoms at remote locations. The observed entanglement fidelity is high enough, opening up the possibility for a first loophole-free test of Bell's inequality [2].

[1] J. Volz, et al., Phys. Rev. Lett. 96, 030404 (2006).

S1.00331 Quantum network with trusted and untrusted relays, XIONGFENG MA, University of Toronto, RAZIEH ANNABESTANI, University of Waterloo, CHI-HANG FRED FUNG, University of Hong Kong, HOI-KWONG LO, University of Toronto, NORBERT LÜTKENHAUS, DAVID PITKÄNEN, University of Waterloo, MOHSEN RAZAVI, University of Leeds — Quantum key distribution offers two distant users to establish a random secure key by exploiting properties of quantum mechanics, whose security has proven in theory. In practice, many lab and field demonstrations have been performed in the last 20 years. Nowadays, quantum network with quantum key distribution systems are tested around the world, such as in China, Europe, Japan and US. In this talk, I will give a brief introduction of recent development for quantum network. For the untrusted relay part, I will introduce the measurement-device-independent quantum key distribution scheme and a quantum relay with linear optics. The security of such scheme is proven without assumptions on the detection devices, where most of quantum hacking strategies are launched. This scheme can be realized with current technology. For the trusted relay part, I will introduce so-called delayed privacy amplification, with which no error correction and privacy amplification is necessarily to be performed between users and the relay. In this way, classical communications and computational power requirement on the relay site will be reduced.

S1.00332 Entanglement witness operator for quantum teleportation¹, ARCHAN S. MAJUMDAR, S. N. Bose National Centre for Basic Sciences, Kolkata, SATYABARTA ADHIKARI, Institute of Physics, Bhubaneswar, NIRMAN GANGULY, JYOTISHMAN CHATTERJEE, Dept. of Mathematics, Heritage Institute of Technology, Kolkata — The ability of entangled states to act as resource for teleportation is linked to a property of the fully entangled fraction. We show that the set of states with their fully entangled fraction bounded by a threshold value required for performing teleportation is both convex and compact. This feature enables for the existence of hermitian witness operators the measurement of which could distinguish unknown states useful for performing teleportation. We present an example of such a witness operator illustrating it for different classes of states. We further discuss the experimental measurability of the witness operator. (arXiv:1108.1493v2 [quant-ph]; to appear in Phys. Rev. Lett.)

S1.00333 Entanglement Entropy in 1-D integrable chains , FABIO FRANCHINI, Massachusetts Institute of Technology/SISSA/INFN, STEFANO EVANGELISTI, Oxford University/University of Bologna/INFN, ELISA ERCOLESSI, FRANCESCO RAVANINI, University of Bologna/INFN, ANDREA DE LUCA, SISSA/INFN — We study analytically the Renyi entropy of a bipartite lattice in the limit of two semi-infinite chains joined at the origin, for a few integrable 1-dimensional models, by using the techniques of Corner Transfer Matrices of the corresponding 2-D classical systems, namely the 8-vertex model and the RSOS. In the scaling limit, close to a conformal point, we reproduce the leading behavior expected from CFT prediction. The sub-leading corrections, however, differ from naïve expectations and we show that lattice effect can give rise to additional relevant terms in any numerical approach. Moreover, in the vicinity of a non-conformal (ferromagnetic) point, we observe a violation of universality and a behavior of the entropy characteristic of an *essential singularity*.

S1.00334 Constant Tip-Surface Distance with Atomic Force Microscopy via Quality Factor Feedback , LIN FAN, DANIEL POTTER, TODD SULCHEK, Georgia Institute of Technology — The atomic force microscope (AFM) is a powerful and widely used instrument to image topography and measure forces at the micrometer and nanometer length scale. Because of the high degree of operating accuracy required of the instrument, small thermal and mechanical drifts of the cantilever and piezoactuator systems hamper measurements as the AFM tip drifts spatially relative to the sample surface. To compensate for the drift, we control the tip-surface distance by monitoring the cantilever quality factor (Q) in a closed loop. Brownian thermal fluctuations provide sufficient actuation to accurately determine cantilever Q by fitting the thermal noise spectrum to a Lorentzian function. We show that the cantilever damping is sufficiently affected by the tip-surface distance so that the tip position of soft cantilevers can be maintained within 70 nm of a setpoint in air and within 3 nm in water with 95 percent reliability. Utilizing this method to hover the tip above a sample surface, we have the capability to study sensitive interactions at the nanometer length scale over long periods of time.

S1.00335 Fractal contours of scalar in smooth flows , MARIJA VUCELJA, Courant Institute of Mathematical Sciences, NYU, GREGORY FALKOVICH, Department of Physics of Complex Systems, Weizmann Institute of Science, 76100 Rehovot, Israel, KONSTANTIN TURITSYN, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA, 02139, USA — A passive scalar field was studied under the action of pumping, diffusion and advection by a smooth flow with a Lagrangian chaos. We present theoretical arguments showing that scalar statistics is not conformal invariant and formulate a new effective semi-analytic algorithm to model scalar turbulence. We then carry out massive numerics of scalar turbulence focusing on nodal lines. The distribution of contours over sizes and perimeters is shown to depend neither on the flow realization nor on the resolution (diffusion) scale for scales exceeding this scale. The scalar isolines are found fractal/smooth at the scales larger/smaller than the pumping scale. We characterize the statistics of bending of a long isoline by the driving function of the Loewner map, show that it behaves like diffusion with diffusivity independent of resolution yet, most surprisingly, dependent on the velocity realization and time (beyond the time on which the statistics of the scalar is stabilized).

S1.00336 Laplace pressure induced droplet generation in micromold for synthesizing monodisperse microspheres. , CHANG-HYUNG CHOI, Chungnam National University, JINKEE LEE, Sungkyunkwan University, CHANG-SOO LEE, Chungnam National University — Microspheres are widely used in applications such MEMS, chemical release systems, optical materials and various biological applications. Here, we report the new micromolding technique for synthesizing spherical monodisperse particles through surface-tension-induced flow. The spherical droplets were prepared using Laplace pressure difference, which is highly depending on geometries of the mold shape, without any pumping system to make flow. We calculated the minimum pressure difference to make the flow moves and form the droplets. It provides a synthetic tool for generating the microspheres using different reaction schemes; UV-polymerization, sol-gel reaction and colloidal assemblies. The monodisperse spherical particles, which are made of various materials, were successfully generated without any surfactant because each droplet can be separately positioned in mold patterns during solidification process.

S1.00337 Tuning the Ferroelectric Properties through a Magnetic Field , JEFFERY CARVELL, RUIHUA CHENG, Indiana University Purdue University Indianapolis — Preparation and characterization of multiferroic materials in which ferroelectricity and ferromagnetism coexist would be a milestone for functionalized materials and devices. We have demonstrated that the electric polarization of ferroelectric polymer, poly(vinylidene fluoride) (PVDF), can be controlled by applying an external magnetic field. Samples were created in a layered heterostructure, with the key part of a PVDF layer sandwiched by two layers of Fe thin films. We found that as the applied magnetic field is changed, the switching of electric polarization for the PVDF displayed a dependence on the external magnetic field. We also noticed that both coercivity and polarization for the PVDF polymer display hysteretic features according to the change of an applied magnetic field. Our study showed that the thickness of both the iron layer and the PVDF layer have an effect on the magnetoelectric coupling in our samples. The same magnetostriction strain applied to a thicker PVDF layer becomes tougher to flip the polarization compared to a thinner PVDF layer. As the iron film thickness increases, the magnetoelectric strain also increases, and the PVDF polymer can be easily saturated and the polarization is more easily flipped. We have shown that it is possible to control the ferroelectric properties of a PVDF film by tuning the magnetic field in heterostructures. Our study shows that this system could have show promising applications for new information technology and devices.

S1.00338 Anderson localization and correlation-induced delocalization in N-leg optical lattices , TIGRAN SEDRAKYAN, Fine Theoretical Physics Institute, University of Minnesota, JASON KESTNER, SANKAR DAS SARMA, University of Maryland, College Park — Recent experiments demonstrated localization of ultracold neutral atoms in a disordered optical potential. The great advantage of these atomic systems is the control of disorder form and strength, interactions, dimensionality, etc., in principle allowing for unambiguous observation of the phenomenon under a variety of circumstances. However, the localization observed so far is qualitatively indistinguishable from classical localization of particles in a disordered trapping potential. We propose a realization of the one-dimensional random dimer model and certain N-leg generalizations using cold atoms in an optical lattice. These models exhibit multiple delocalization energies that depend strongly on the symmetry properties of the corresponding Hamiltonian. We demonstrate that the N-leg systems possess similarities with their 1D ancestors but are demonstrably distinct. The existence of critical delocalization energies leads to dips in the momentum distribution which serve as a clear signal of the localization-delocalization transition.

S1.00339 Multidimensional scaling of ideological landscape on social network sites , DEOKJAE LEE, Department of Physics and Astronomy, Seoul National University, KYU S. HAHN, Department of Communication, Seoul National University, JUYONG PARK, Department of Physics, Kyung Hee University — Social network sites (SNSs) are valuable source of information on various subjects in network science. Recently, political activity of SNSs users has increasing attention and is an interesting interdisciplinary subject of physical and social science. In this work, we measure ideological positions of the legislators of U.S. and South Korea (S.K.) evaluated by Twitter users, using the information employed in the bipartite network structure of the legislators and their Twitter followers. We compare the result with ideological positions constructed from roll call record of the legislators. This shows there is a discrepancy between the ideological positions evaluated by Twitter users and actual positions estimated from roll call votes in S.K. We also assess the ideological positions of the Twitter users themselves and analyze the distribution of the positions.

S1.00340 Some Recent Developments in Structure and Glassy Behavior of Proteins¹, CHIN-KUN HU, Institute of Physics of Academia Sinica, Taipei, Taiwan — We have used ARVO developed by us to find that the ratio of volume and surface area of proteins in Protein Data Bank distributed in a very narrow region [1]. Such result is useful for the determination of protein 3D structures. It has been widely known that a spin glass model can be used to understand the slow relaxation behavior of a glass at low temperatures [2]. We have used molecular dynamics and simple models of polymer chains to study relaxation and aggregation of proteins under various conditions and found that polymer chains with neighboring monomers connected by rigid bonds can relax very slowly and show glassy behavior [3]. We have also found that native collagen fibrils show glassy behavior at room temperatures [4]. The results of [3] and [4] about the glassy behavior of polymers or proteins are useful for understanding the mechanism for a biological system to maintain in a non-equilibrium state, including the ancient seed [5], which can maintain in a non-equilibrium state for a very long time. S1.00341 Effective spectral dimension of hub in scale-free networks, SUNGMIN HWANG, Department of Physics and Astronomy, Seoul National University, DEOK-SUN LEE, Department of Natural Medical Sciences and Department of Physics, Inha University, BYUNGNAM KAHNG, Department of Physics and Astronomy, Seoul National University — Exploring the World Wide Web has become one of the key issues in information science, specifically in context of its application to the PageRank-like algorithms used in search engine. The random walk approach has been employed to study such a problem. The probability of the return to the origin (RTO) of random walks is inversely related to how information can be accessed during random surfing. We find analytically that the RTO probability for a given starting node shows a crossover from a slow to a fast decay behavior with time and the crossover time increases with the degree of the starting node. Furthermore, the RTO probability is almost constant in the early-time regime as the degree exponent approaches two. This result indicates that a random surfer can be effectively trapped at the hub and supports the necessity of the random jump strategy empirically used in the Google's search engine.

S1.00342 Rings and boxes in dissipative environments, BARUCH HOROVITZ, Ben-Gurion University, Israel — We study a particle on a ring in presence of a dissipative Caldeira-Leggett environment and derive its response to a DC field [1]. We find, through a 2-loop renormalization group analysis, that a large dissipation parameter η flows to a fixed point $\eta^R = \hbar/2\pi$. We also reexamine the mapping of this problem to that of the Coulomb box and show that the relaxation resistance, of recent interest, has a certain average that is quantized for $\eta > \eta^R$, leading to quantized noise. We propose a box experiment to detect this noise. When the particle carries a spin with spin-orbit interactions [2] we find that the spin correlations in the direction perpendicular to the ring are finite at long times, i.e. do not dephase, while the parallel components may decay as a power law at strong dissipation.

S1.00343 JV Annealing Study of P3HT:PCBM OPV, ROY MURRAY, University of Delaware, STEVE HEGEDUS, IEC, University of Delaware, S. ISMAT SHAH, Department of Physics and Department of Materials Science, University of Delaware — Current-voltage (JV) analysis of poly (3-hexylthiophene) (P3HT) and phenyl-C61-butyric acid methyl ester (PCBM) organic photovoltaics (OPV) yield valuable insight into the internal physics of devices. A simple lumped circuit model, previously used to analyze various thin film photovoltaics and more recently applied to OPV has been used to study annealing parameters. An annealing study of P3HT:PCBM blend OPV was carried out using the lumped circuit model. Limiting carrier lifetime-mobility product information and barrier data were extracted from the JV analysis of these devices. Collection loss characteristics were also obtained. The data was used to better characterize annealing effects.

S1.00344 Hydrogen adsorption around a hydrogen atom anchored in a graphene vacancy, GERARDO VAZQUEZ, FERNANDO MAGANA, Instituto de Fisica, UNAM, EDUARDO RANGEL, Instituto de Investigacion en Materiales, UNAM — In this work, we study the adsorption of hydrogen molecules around a hydrogen atom anchored in a graphene vacancy. We used density functional theory and molecular dynamics. To study the adsorption of hydrogen molecules on the system we used three hydrogen molecules around each hydrogen atom. It was found that raising the temperature of the system up to 900 K the hydrogen molecules remained linked to the system of graphene doped with hydrogen. The results show that doping graphene with atomic hydrogen can be useful to store hydrogen molecules in the system.

S1.00345 Beyond the Hubbard model: best effective single dressed band description of interacting atoms in optical lattices¹, ULF BISSBORT, FRANK DEURETZBACHER, WALTER HOFSTETTER, Goethe Universität Frankfurt a.M. — We construct the effective lowest-band Bose-Hubbard model incorporating interaction-induced on-site correlations. The model is based on ladder operators for local correlated states, which deviate from the usual Wannier creation and annihilation operators, allowing for a systematic construction of the most appropriate single-band low-energy description in form of the extended Bose-Hubbard model. A formulation of this model in terms of ladder operators not only naturally contains the previously found effective multi-body interactions, but also contains multi-body induced single particle tunneling, pair tunneling and nearest-neighbor interaction processes of higher orders. An alternative description of the same model can be formulated in terms of occupation-dependent Bose-Hubbard parameters. These multi-particle effects can be enhanced using Feshbach resonances, leading to corrections which are well within experimental reach and of significance to the phase diagram of ultracold bosonic atoms in an optical lattice. We analyze the energy reduction mechanism of interacting atoms on a local lattice site and show that this cannot be explained only by a spatial broadening of Wannier orbitals on a single particle level, which neglects correlations.

S1.00346 Doping-induced evolution of superconducting gap in iron-based superconductors: a point-contact Andreev reflection study of BaNi-122 single crystals¹, CONG REN, ZHAOSHENG WANG, BING SHEN, HUIQIAN LUO, XINGYE LU, ZHENYU WANG, JUN ZHU, JUN GONG, XINGYUAN HOU, CHUNHONG LI, LEI SHAN, Laboratory for Superconductivity, Institute of Physics, HUAN YANG, HAIHU WEN, Department of Physics, Nanjing University — We report a systematic investigation on c-axis point-contact Andreev reflection (PCAR) in superconducting $\text{BaFe}_{2-x}\text{Ni}_x\text{As}_2$ single crystals from underdoped to overdoped regions ($0.075 < x < 0.15$). At optimal doping ($x = 0.1$) the PCAR spectrum feature a dip-hump structure at the edge of the conductance gap, which corresponds to electron-boson coupling mode in energy scale. Two-superconducting-gap structure is resolved in the PCAR spectroscopy. In the $s_{\pm}$ scenario, quantitative analysis using a generalized Blonder-Tinkham-Klapwijk (BTK) formalism with two gaps: one isotropic and another angle dependent, suggest a nodeless state in strong-coupling limit with gap minima on the Fermi surfaces. Upon crossing above the optimal doping ($x > 0.1$), the PCAR spectrum show an in-gap sharp narrow peak at low bias, in contrast to the case of underdoped samples ($x < 0.1$), signaling the onset of deepened gap minima or nodes in the superconducting gap. This result provides evidence of the modulation of the gap amplitude with doping concentration, consistent with the calculations for the orbital dependent pair interaction mediated by the antiferromagne

S1.00347 Discontinuous percolation transition in hidden in continuous percolation transition, YOUNG SUL CHO, BYUNGNAM KAHNG, Seoul National University — Diffusion limited cluster aggregation model is the well known model which describes the aggregation of diffusive clusters. In this model, time t is defined so as to describe the situation in which clusters follow Brownian motion. Thus t defined in this model can be regarded as real time. In this presentation, we introduce a new variable p which increases as much as $\delta p = 1/N$ whenever two distinct clusters aggregate. We use p instead of t to study a percolation problem in diffusion limited cluster aggregation model. Then, we find that a discontinuous percolation transition occurs if we observe the growth of the largest cluster as a function of the transformed variable p . This result implies that a continuous percolation transition can be observed as a discontinuous percolation transition when a controlled parameter is changed.

S1.00348 The magnetic flux periodicity in SNS square ring., HONG-YI CHEN, National Taiwan Normal University, CHUNG-PIN CHOU, Academia Sinica, Taiwan — In this work, we study the magnetic flux periodicity of d-wave superconductor-normal-superconductor square ring. The Hamiltonian of the SNS square ring is solved by using self-consistent Bogoliubov-de Gennes equations. The total current as a function of flux exhibits the hc/e period. As we increase the length of the normal metal, the hc/e period becomes $hc/2e$ period. Furthermore, we also investigate the behavior of the supercurrent in SNS and SIS junctions and the phase variation of the Josephson current.

S1.00349 High Pressure Ultrasonic and Transport Studies of Cerium Skutterudite Thermoelectrics¹, MATTHEW JACOBSEN, WEI LIU, WEI ZHU, Mineral Physics Institute, Stony Brook University, QIANG LI, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, BAOSHENG LI, Mineral Physics Institute, Stony Brook University — In the effort to find more efficient thermoelectric materials, some skutterudite materials based on CoSb_3 have shown that these materials have the potential of being effective at elevated temperatures. This work will present high pressure ultrasonic and transport measurements on the cerium filled versions of this parent compound, $\text{CeFe}_4\text{Sb}_{12}$ and $\text{CeFe}_3\text{CoSb}_{12}$. A previous study on these materials showed an anomaly in the equation of state for these materials originally attributed to the vitrification of a Methanol:Ethanol pressure medium. However, the studies performed as a part of this work demonstrate that, while this may be partly to blame, there is some contribution due to a real effect in this material.

S1.00350 Topological Superfluid in P-band Optical Lattice¹, YA-JIE WU, JING HE, CHUN-LI ZANG, SU-PENG KOU, Department of physics, Beijing Normal University, CONDENSED MATTER PHYSICS GROUP TEAM — By studying p-band fermionic system with nearest neighbor attractive interaction we find translation symmetry protected Z_2 topological superfluid (TSF) that is characterized by a special fermion parity pattern at high symmetry points in momentum space $k = (0, 0)$, $(0, \pi)$, $(\pi, 0)$, (π, π) . Such Z_2 TSF supports the robust Majorana edge modes and a new type of low energy excitation - (supersymmetric) Z_2 link-excitation.

Wednesday, February 29, 2012 2:30PM - 5:30PM –
Session T1 DAMOP: Hybrid Systems, Optomechanics and Macroscopic Systems at the Quantum Limit II 203

2:30PM T1.00001 Coupling propagating acoustic waves to quantum circuits, MARTIN GUSTAFSSON, Chalmers University of Technology, PAULO SANTOS, Paul-Drude-Institut für Festkörperelektronik, GÖRAN JOHANSSON, PER DELSING, Chalmers University of Technology — We present a method for coupling propagating Surface Acoustic Waves (SAW) to charge sensitive quantum circuits, by direct piezoelectric charge induction. Using an RF-Single Electron Transistor¹ as a high-performance electrometer, and employing an on-chip mixing technique², we demonstrate ultra-high displacement sensitivity in the gigahertz frequency range, and an averaged detection sensitivity below the single-phonon level. Based on these experimental results, we discuss how the method can be enhanced and extended to superconducting qubits, and what roles Surface Acoustic Waves could potentially play in novel hybrid quantum devices.

2:42PM T1.00002 Single Crystal Diamond Mechanical Resonators¹ , PREETI OVARTCHAIYAPONG, BRYAN MYERS, PAUL LAURIA, ANIA BLESZYNSKI JAYICH, University of California Santa Barbara — We report on the fabrication and measurement of single crystal diamond mechanical resonators. This is an important step towards realizing diamond photonics, optomechanics, and diamond-based scanning magnetometers. We present measurements of mechanical quality factors in excess of 10,000 as well as estimates of the coupling to embedded nitrogen-vacancy (NV) centers through strain. Strain tuning the NV's zero-phonon line could facilitate coupling its spin state to a photonic network. We also discuss strain as a coupling mechanism between the spin and mechanical degree of freedom in a diamond based resonator.

2:54PM T1.00003 Resonant Optical Forces in Silicon Carbide Nanostructures , DONGFANG LI, RASHID ZIA, Brown University — Silicon carbide (SiC) materials are widely used for their exceptional electronic, mechanical, and thermal properties. For example, given its high stiffness to density ratio, SiC is an ideal material for mechanical resonators, and it has been explored for applications in nanoelectromechanical systems (NEMS). SiC also supports strong surface phonon-polariton resonances in the infrared region, which could enable its use for optomechanics. Similar to surface plasmon-polaritons supported by metal-dielectric interfaces, these surface waves at a SiC-vacuum interface can be used to guide and confine intense electromagnetic energy. Here, we investigate the resonant optical forces induced by phonon-polariton modes in different SiC nanostructures. Specifically, we calculate optical forces using the Maxwell Stress Tensor for three geometries: spherical particles, slab waveguides, and rectangular waveguides. We find that the high quality factor phonon-polariton modes in SiC can produce very large forces, more than two orders of magnitude larger than the plasmonic forces in similar metal nanostructures. These strong resonant forces, combined with its mechanical and thermal properties, make SiC a promising material for optomechanical applications.

3:06PM T1.00004 Quantum Mechanical Scattering in Nanoscale Systems¹ , A.G. GIANFRANCESCO, A. ILYASHENKO, C.R. BOUCHER, L.R. RAM-MOHAN, Worcester Polytechnic Institute — We investigate quantum scattering using the finite element method. Unlike textbook treatments employing asymptotic boundary conditions (BCs), we use modified BCs, which permits computation close to the near-field region and reduces the Cauchy BCs to Dirichlet BCs, greatly simplifying the analysis. Scattering from any finite quantum mechanical potential can be modeled, including scattering in a finite waveguide geometry and in the open domain. Being numerical, our analysis goes beyond the Born Approximation, and the finite element approach allows us to transcend geometric constraints. Results of the formulation will be presented with several case studies, including spin dependent scattering, demonstrating the high accuracy and flexibility attained in this approach.

3:18PM T1.00005 Modeling time domain spectroscopy of electron-phonon coupled systems out of equilibrium , MICHAEL SENTEF, A.F. KEMPER, BRIAN MORITZ, T.P. DEVEREAUX, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory, 2575 Sand Hill Road, Menlo Park, CA 94025, USA — Recent advances in Terahertz large-electric field generation and pump-probe spectroscopies resolving pico- and even femtosecond time scales allow to study the behavior of photoexcited solids out of equilibrium. The relaxation after the pump pulse typically involves very fast processes related to purely electronic degrees of freedom, but for the slower return back to equilibrium it is essential to understand the interplay of electronic and lattice degrees of freedom. We present a theoretical investigation of electron-phonon coupled systems out of equilibrium, with results for various quantities (electronic distribution function, time-resolved angle-resolved photoemission, charge current). Our results show that the experimentally observed behavior can be related to the underlying microscopic properties of the system.

3:30PM T1.00006 Modeling lattice interaction in non-equilibrium pump-probe experiments , A.F. KEMPER, MICHAEL SENTEF, BRIAN MORITZ, T.P. DEVEREAUX, Stanford Institute for Materials and Energy Science — In past years, advances in experimental laser technology have allowed for the study of materials at ever shorter timescales. In these pump-probe experiments, after excitation by the pulse, the systems evolve back to equilibrium through its inherent relaxation processes, which are typically temporally separated by their characteristic timescales. Among the slower processes are the electron-phonon interactions, which carry the majority of the energy transferred to the electrons away into the lattice. We present a direct calculation of the characteristic timescales for systems driven out of equilibrium via a short pulse and allowed to relax via electron-phonon interactions. We make a direct connection between the observable timescales and the microscopic specifics, both via decay rates and oscillations in various photon-spectroscopies.

3:42PM T1.00007 Fluctuation Induced Forces for Surface Relief Gratings , JEF WAGNER, ROYA ZANDI, University of California Riverside, THORSTEN EMIG, Laboratoire de Physique Theorique et Modeles Statistiques Universite Paris Sud — In 1948 H. G. B. Casimir predicted that two flat parallel neutral perfectly conducting plates would attract each other due to the quantum fluctuations of the electromagnetic field. Since then progress has been made to allow one to calculate the interaction energy due to both quantum and thermal fluctuations between two objects of almost arbitrary shape and material properties. This work focuses on interaction with at least one object described by a surface relief grating. The Casimir energy is calculated using the scattering matrix approach, and the scattering matrix of the periodic surface is calculated using the C method from electromagnetic grating theory. The strengths and limitations of the method with regards to calculating the Casimir energy are discussed, and the results for simple 1-D and 2-D periodic structures are shown.

3:54PM T1.00008 Superfluid to Mott-Insulator Transition in Thermodynamic Limit of 1D Coupled Cavity Array , ADAM G. D'SOUZA, BARRY C. SANDERS, DAVID L. FEDER, IQIS, University of Calgary — In recent years, there has been great interest in simulating condensed matter models with quantum optical systems, which are usually characterized by a high degree of experimental control. One such model is the Jaynes-Cummings-Hubbard (JCH) model, an analog for the Bose-Hubbard (BH) model, in which mobile photons interact with atoms localized within a regular lattice of weakly coupled cavities. Finite system Density Matrix Renormalization Group (DMRG) studies have predicted a superfluid (SF) to Mott insulator (MI) transition in the phase diagram of the JCH model, and finite-size scaling has been used to determine the phase boundary in the thermodynamic limit. In this work, we directly numerically investigate the JCH model in the thermodynamic limit using infinite-system DMRG. The preliminary results indicate that the properties of the expected SF state are not wholly consistent with those of a conventional superfluid.

4:06PM T1.00009 Dirac Exciton-Polariton Condensates in a Triangular Lattice , NA YOUNG KIM, Stanford University, KENICHIRO KUSUDO, National Institute of Informatics, SVEN HOEFLING, ALFRED FORCHÉL, University of Wuerzburg, YOSHIHISA YAMAMOTO, Stanford University — Microcavity exciton-polaritons are quantum bose particles arising from the strong light-matter coupling between cavity photons and quantum well excitons. Recently, we have investigated the behavior of condensates in artificial lattice geometries in two-dimension (2D). Coherent *p*- and *d*-orbital state in a 2D square lattice is recently observed. Here we investigate exciton-polariton condensates at Dirac points formed in a 2D triangular lattice and experimental mapping of Dirac dispersion and discuss the interaction effect. We anticipate that the preparation of high-orbital condensates can be further extended to probe dynamical quantum phase transition in a controlled manner as quantum simulation applications.

4:18PM T1.00010 Numerical Study of the Bose-Einstein Condensation of Exciton-Polaritons ,

ASLAN KASIMOV, JESUS SIERRA, King Abdullah University of Science and Technology, RADA-MARIA WEISHÄUPL, Vienna University — Using the complex Gross-Pitaevskii equation (cGPE) with pumping and decay terms that models the Bose-Einstein condensate of exciton-polaritons, we numerically investigate the dynamics of instability of its radially symmetric steady solutions. We develop accurate algorithms for computing the steady state solution, the linear stability spectra, as well as the full nonlinear solutions of the cGPE. We accurately compute the thresholds of instability that depend, e.g. on the strength and size of the polariton pumping spot and observe the formation of vortices and such complex dynamics as the formation of vortex lattices and nucleation.

4:30PM T1.00011 Formation and decay of a Bose-Einstein condensate of trapped dipole ex-

citons , GERMAN KOLMAKOV, OLEG BERMAN, ROMAN KEZERASHVILI, New York City College of Technology CUNY, YURII LOZOVIK, Institute of Spectroscopy RAS — We study the nonlinear dynamics of formation and decay of a Bose-Einstein condensate of dipole excitons trapped in an external confining potential in coupled quantum wells. The problem is considered within an analytical approach and in numerical simulations. The trap restricts the spatial distribution of excitons and results in non-uniform density distribution in the exciton cloud. We demonstrate that under typical experimental conditions, regardless of a long-range nonlocal interaction of the dipole excitons, the system can be described by a generalized Gross-Pitaevskii equation with the local interaction between the excitons, and we find the effective interaction constant. In the numerical simulations, we account for the finite lifetime of dipole excitons and generation of the excitons due to continuous laser pumping. We also discuss formation and decay of vortex states in the condensate.

4:42PM T1.00012 Measurement of Casimir force with magnetic materials Alexandr Banishev, Chia-Cheng Chang, Umar Mohideen Department of Physics and Astronomy, University of Cal-

ifornia, Riverside, USA , ALEXANDR BANISHEV, CHIA-CHENG CHANG, UMAR MOHIDEEN , Department of Physics and Astronomy, University of California, Riverside — The Casimir effect is important in various fields from atomic physics to nanotechnology. According to the Lifshitz theory of the Casimir force, the interaction between two objects depends both on their dielectric permittivity and magnetic permeability. Thus the role of magnetic properties on the Casimir force is interesting particularly due to the possibility of a reduction the Casimir force. In this report we will present the results of a Casimir force measurement between a magnetic material such as nickel coated on SiO₂ plate and a Au-coated sphere.

4:54PM T1.00013 Geometry and fluctuation induced (Casimir) forces ,

SHOMEK MUKHOPADHYAY, EHSAN NORUZIFAR, UMAR MOHIDEEN, University of California , Riverside — Since the original prediction of attraction between parallel, perfectly conducting plates by Casimir there has been significant amount of work done in extending the calculations to real materials, finite temperatures and micro or nanostructured geometries. Majority of the experimental work has been carried out in the sphere-plane geometry. In this talk we will present ongoing experimental work on sphere-cylinder and sphere-cone geometries using frequency modulated atomic force microscopy. We will discuss numerical results in the sphere cylinder geometry and the range of validity of the point force approximation(PFA).

5:06PM T1.00014 Temperature dependence of Casimir force ,

JUN XU, University of California, Riverside, RODRIGO CASTILLO-GARZA, University of Texas,Austin, ROBERT SCHAFER, SHOMEK MUKHOPADHYAY, UMAR MOHIDEEN, University of California, Riverside — Most of the experimental work till date on Casimir forces have been performed at or near room temperature. We report on our measurements of Casimir forces performed at liquid helium and liquid nitrogen temperatures using gold coated sphere and plate. These measurements were performed on a home built Atomic Force Microscope with a phase locked loop to track the frequency shift. We will discuss the results in the context of current theoretical understanding of temperature dependence in the sphere – plate geometry.

5:18PM T1.00015 Enhanced light-matter interactions of a single emitter coupled to a slot waveguide ,

MAIKEN H. MIKKELSEN, NITIPAT PHOLCHAI, PAVEL KOLCHIN, NSF Nanoscale Science and Engineering Center (NSEC), 3112 Etcheverry Hall, University of California, Berkeley, CA 94720, USA, JINYONG OH, M. SAIF ISLAM, Department of Electrical and Computer Engineering, 2064 Kemper Hall, University of California, Davis, CA95616, USA, XIANG ZHANG, NSF Nanoscale Science and Engineering Center (NSEC), 3112 Etcheverry Hall, University of California, Berkeley, CA 94720, USA — Traditionally, enhanced light-matter interactions are achieved using either plasmonic structures or photonic crystals. However, these structures suffer from inherent metal losses or narrow operating bandwidth. Instead, here we use an all-dielectric waveguide structure with ultra-small mode volume and low-loss and broadband capabilities. A slot-waveguide architecture is used for deep sub-wavelength light confinement in a low-index material surrounded by high-index barriers. Individual colloidal quantum dots are controllably coupled to this waveguide mode. A large Purcell enhancement is observed from lifetime measurements of the spontaneous emission rate of the quantum dot before and after coupling to the waveguide. Second order intensity correlation measurements verify that the observed fluorescence is indeed due to a single quantum dot. The demonstrated system is a promising broadband and low-loss platform for quantum information applications.

Session T2 FIP: Invited Session: PIRE in Condensed Matter 204AB

2:30PM T2.00001 Terahertz Dynamics in Carbon Nanomaterials¹ ,

JUNICHIRO KONO, Rice University — This NSF Partnerships for International Research and Education (PIRE) project supports a unique interdisciplinary and international partnership investigating terahertz (THz) dynamics in nanostructures. The 0.1 to 10 THz frequency range of the electromagnetic spectrum is where electrical transport and optical transitions merge, offering exciting opportunities to study a variety of novel physical phenomena in condensed matter. By combining THz technology and nanotechnology, we can advance our understanding of THz physics while improving and developing THz devices. Specifically, this PIRE research explores THz dynamics of electrons in carbon nanomaterials, namely, nanotubes and graphene — low-dimensional, *sp*²-bonded carbon systems with unique finite-frequency properties. Japan and the U.S. are global leaders in both THz research and carbon research, and stimulating cooperation is critical to further advance THz science and to commercialize products developed in the lab. However, obstacles exist for international collaboration — primarily linguistic and cultural barriers — and this PIRE project aims to address these barriers through the integration of our research and education programs. Our strong educational portfolio endeavours to cultivate interest in nanotechnology amongst young U.S. undergraduate students and encourage them to pursue graduate study and academic research in the physical sciences, especially those from underrepresented groups. Our award-winning International Research Experience for Undergraduates Program, NanoJapan, provides structured research internships in Japanese university laboratories with Japanese mentors — recognized as a model international education program for science and engineering students. The project builds the skill sets of nanoscience researchers and students by cultivating international and inter-cultural awareness, research expertise, and specific academic interests in nanotechnology. U.S. project partners include Rice University, the University of Florida, the University of Tulsa, the State University of New York at Buffalo, Southern Illinois University at Carbondale, and Texas A&M University. Japanese partners include: Osaka University, Chiba University, Shinshu University, Tohoku University, the University of Tokyo, the National Institute of Information and Communications Technology, the National Institute of Materials Science, Hokkaido University, RIKEN, and the University of Aizu.

¹This PIRE project is cofunded by the Office of International Science and Engineering, the Division of Electrical, Communications, and Cyber Systems, and the Division of Materials Research of the National Science Foundation.

3:06PM T2.00002 Petascale Many Body Methods for Complex Correlated Systems, THOMAS PRUSCHKE, Georg-August-Universität Göttingen — Correlated systems constitute an important class of materials in modern condensed matter physics. Correlation among electrons are at the heart of all ordering phenomena and many intriguing novel aspects, such as quantum phase transitions or topological insulators, observed in a variety of compounds. Yet, theoretically describing these phenomena is still a formidable task, even if one restricts the models used to the smallest possible set of degrees of freedom. Here, modern computer architectures play an essential role, and the joint effort to devise efficient algorithms and implement them on state-of-the-art hardware has become an extremely active field in condensed-matter research. To tackle this task single-handed is quite obviously not possible. The NSF-OISE funded PIRE collaboration “Graduate Education and Research in Petascale Many Body Methods for Complex Correlated Systems” is a successful initiative to bring together leading experts around the world to form a virtual international organization for addressing these emerging challenges and educate the next generation of computational condensed matter physicists. The collaboration includes research groups developing novel theoretical tools to reliably and systematically study correlated solids, experts in efficient computational algorithms needed to solve the emerging equations, and those able to use modern heterogeneous computer architectures to make them working tools for the growing community.

3:42PM T2.00003 Polymers at Interfaces: US-Korea International Research and Education Partnership¹, CHANG YEOL RYU, Rensselaer Polytechnic Institute — Our NSF program of Partnership for International Research and Education (PIRE) is focused on the development and training of graduate, undergraduate students and faculty members in the field of polymer physics by promoting both domestic and international research collaborations with specific exchange opportunities for both US and Korean participants. This collaborative effort by a group of 5 US faculty members is motivated by the global partnership with Korean polymer physicists to promote novel opportunities in polymer science research and education. Our PIRE program involves a focused research plan at the forefront of polymer physics based on the synthesis, separation, characterization, and theory of synthetic polymers in bulk and at interfaces. The multifaceted research activities spanning the areas of polymer synthesis, characterization, property modifications and their modeling will be presented to advance our knowledge on polymer behaviors at interfaces.

¹NSF OISE PIRE 0730243

4:18PM T2.00004 SPIRE, the “Spin Triangle”: Athens, Hamburg, Buenos Aires: Advancing Nanospintronics and Nanomagnetism¹, ARTHUR R. SMITH, Ohio University Nanoscale and Quantum Phenomena Institute — Future technological advances at the frontier of ‘elec’tronics will increasingly rely on the use of the spin property of the electron at ever smaller length scales. As a result, it is critical to make substantial efforts towards understanding and ultimately controlling spin and magnetism at the nanoscale. In SPIRE, the goal is to achieve these important scientific advancements through a unique combination of experimental and theoretical techniques, as well as complementary expertise and coherent efforts across three continents. The key experimental tool of choice is spin-polarized scanning tunneling microscopy – the premier method for accessing the spin structure of surfaces and nanostructures with resolution down to the atomic scale. At the same time, atom and molecule deposition and manipulation schemes are added in order to both atomically engineer, and precisely investigate, novel nanoscale spin structures. These efforts are being applied to an array of physical systems, including single magnetic atomic layers, self-assembled 2-D molecular arrays, single adatoms and molecules, and alloyed spintronic materials. Efforts are aimed at exploring complex spin structures and phenomena occurring in these systems. At the same time, the problems are approached, and in some cases guided, by the use of leading theoretical tools, including analytical approaches such as renormalization group theory, and computational approaches such as first principles density functional theory. The scientific goals of the project are achieved by a collaborative effort with the international partners, engaging students at all levels who, through their research experiences both at home and abroad, gain international research outlooks as well as understandings of cultural differences, by working on intriguing problems of mutual interest. A novel scientific journalism internship program based at Ohio University furthers the project’s broader impacts.

¹The NSF PIRE program is gratefully acknowledged.

4:54PM T2.00005 Super-PIRE: International Consortium for Proving Novel Superconductors¹, YASUTOMO UEMURA, Department of Physics, Columbia University — The Super-PIRE project aims to study high-T_c cuprates, FeAs, heavy-fermion and other unconventional superconductors by using neutron scattering, muon spin relaxation, X-ray scattering, optical conductivity, ARPES and STM measurements in international collaboration. The project includes US PI’s Billinge, Pasupathy, Uemura (Columbia), and Dai (UTK/ORNL), Project Partner (PP) Balatsky (LANL), and foreign PI’s Uchida, Tajima, Maekawa, Eisaki (Japan), Hayden (UK), Wang (China), Luke (Canada), and about 40 additional “Local Experts” from institutions of the PI/PP’s. In this talk, we introduce the organization of the project, initial scientific products including 4 papers published in Nature group journals, and the out-reach effort centered in organizing special graduate and undergraduate courses at Columbia recorded as voice-synchronized ppt presentations, and then broadcasted in a class-room of Tokyo University. Homepage address: <http://www.phys.utk.edu/superpire/members.html>

¹NSF OISE-0968226

Wednesday, February 29, 2012 2:30PM - 5:30PM – Session T4 DAMOP: Vortices, Rotation, and Synthetic Gauge Fields 205C

2:30PM T4.00001 Rotating Ultracold Fermi Gases: Reduction in the Moment of Inertia Above the Superfluid Transition Temperature, K. LEVIN, VIVEK MISHRA, DAN WULIN, James Franck Institute, University of Chicago — There has been considerable interest in the viscosity of ultracold Fermi gases which is found to be anomalously suppressed even in the normal phase. This suppression, believed to derive from pseudogap effects, is also associated with a reduction in the moment of inertia, as measured by the Duke group. In this talk we address the relationship between viscosity and the reduced moment of inertia. We emphasize the very strong relation of the latter to the anomalous normal state diamagnetism of the high temperature superconductors. We present a simple physical picture for the origin of these related phenomena. Our picture gains strong support from establishing sum rule compatibility and leads to testable predictions.

2:42PM T4.00002 Vortices in spin-orbit-coupled Bose-Einstein condensates, JURAJ RADIC, TIGRAN A. SEDRAKYAN, Joint Quantum Institute, University of Maryland, College Park, IAN B. SPIELMAN, Joint Quantum Institute, University of Maryland, College Park and NIST, Gaithersburg, VICTOR GALITSKI, Joint Quantum Institute, University of Maryland, College Park — We discuss realistic methods to create vortices in spin-orbit-coupled Bose-Einstein condensates. We show that, contrary to common intuition, rotation of the trap containing a spin-orbit-coupled condensate does not lead to an equilibrium state with static vortex structures but gives rise instead to intrinsically time-dependent Hamiltonian. We propose alternative methods to create stable static vortex configurations: (1) to rotate both the lasers and the anisotropic trap; and (2) to impose a synthetic Abelian field on top of synthetic spin-orbit interactions. We derive the effective Hamiltonians for spin-orbit condensates under such perturbations for most currently known realistic laser schemes that induce synthetic spin-orbit couplings and we solve the Gross-Pitaevskii equation for several experimentally relevant regimes. The new interesting effects include spatial separation of left- and right-moving spin-orbit condensates and the appearance of unusual vortex arrangements.

2:54PM T4.00003 2D Vortex Dynamics and Quantum Tunneling in the Lowest Landau Level Limit, ROHIT HEGDE, Department of Physics, University of Texas at Austin, CHARLES B. HANNA, Department of Physics, Boise State University, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin — We examine the collective excitation spectrum of a rapidly rotating cold Bose gas in the lowest Landau level regime. The Gross-Pitaevskii action can be equivalently expressed in terms of the angular momentum state expansion of the boson field or in terms of 2D vortex positions. We emphasize the very different role of visible and invisible vortices in the latter formulation and discuss the significance of non-standard non-local Berry phase coupling between separated vortices in the boson action. We also consider dissipative quantum tunneling of a single vortex, allowing for linear coupling to a bath of quadratic fluctuations of the lattice following the Caldeira-Leggett model, and comment on differences between the lowest Landau level limit and the case of vortices in a slowly rotating superfluid.

3:06PM T4.00004 Screening properties and phase transitions in unconventional plasmas for Ising-type quantum Hall states¹, EGIL V. HERLAND, Norwegian University of Science and Technology, EGOR BABAEV, UMass Amherst and KTH Stockholm, PARSA BENDERSON, Microsoft Research, Station Q, VICTOR GURARIE, University of Colorado, Boulder, CHETAN NAYAK, Microsoft Research, Station Q and University of California, Santa Barbara, ASLE SUDBO, Norwegian University of Science and Technology — Utilizing large-scale Monte-Carlo simulations, we investigate an unconventional two-component classical plasma in two dimensions that interacts with two different Coulomb interactions. This plasma controls the behavior of the norms and overlaps of the quantum-mechanical wavefunctions of Ising-type quantum Hall states. It also relates to a model for a rotating two-component Bose-Einstein condensate with an Andreev-Bashkin drag interaction. The plasma differs fundamentally from that which is associated with the two-dimensional XY model and Abelian fractional quantum Hall states. We find that this unconventional plasma undergoes a Berezinskii-Kosterlitz-Thouless phase transition from an insulator to a metal and that the parameter values corresponding to Ising-type quantum Hall states lie on the metallic side of this transition. This result verifies the required properties of the unconventional plasma used to demonstrate that Ising-type quantum Hall states possess quasiparticles with non-Abelian braiding statistics.

¹Supported by the Knut and Alice Wallenberg Foundation, NSF grants No. DMR-0955902, No. PHY-0904017, DARPA QuEST program, NRC Grant No. 205591/V30 (FRINAT).

3:18PM T4.00005 Edge excitations of bosonic fractional quantum Hall phases in optical lattices, JONAS KJALL, JOEL MOORE, University of California, Berkeley — With the rapid development in ultracold gases, the realization of a fractional quantum Hall state on a lattice draws nearer. We investigate the impact of finite size effects in these kind of systems including different trapping potentials. A good understanding of finite size effects is essential for designing experiments and the edge excitations will likely be the best way to experimentally determine the topological order of the bulk. We find different fractional quantum Hall phases for bosons in a circular harmonic trap as the flux of the synthetic gauge field is varied, including phases like $\nu = 1/2$ and $\nu = 2/3$ with different edge spectra.

3:30PM T4.00006 Finite temperature phase structures of hard-core bosons in an optical lattice with a synthetic magnetic field¹, KENICHI KASAMATSU, YUKI NAKANO, TETSUO MATSUI, Department of Physics, Kinki University — We study finite temperature phase structures of hard-core bosons in a two-dimensional optical lattice subject to a synthetic magnetic field by employing the gauged CP¹ model. Based on the extensive Monte Carlo simulations, we study their phase structures at finite temperatures for several values of the magnetic flux per plaquette of the lattice and mean particle density. Despite the presence of the particle number fluctuation, the thermodynamic properties are qualitatively similar to those of the frustrated XY model with only the phase as a dynamical variable.

¹One of the authors (K.K.) is supported in part by Grant-in-Aid for Scientific Research (Grant No. 21740267) from MEXT, Japan.

3:42PM T4.00007 Modulated superfluid phases of lattice bosons in a non-abelian gauge field¹, WILLIAM COLE, SHIZHONG ZHANG, NANDINI TRIVEDI, Department of Physics, The Ohio State University, Columbus OH 43210 — We consider the two-component Bose-Hubbard model subject to non-abelian gauge fields that give rise to spin-orbit coupling. We obtain the phase diagram based on an extended mean field theory and find many exotic superfluid phases (polarized, striped, checkerboard). We characterize the superfluid phases by finding their collective excitations within random phase approximation (RPA) and discuss the possibility of novel topological defects.

¹We acknowledge support from ARO W911NF-08-1-0338, DARPA OLE program (WC,SZ) and NSF DMR-0907275 (NT).

3:54PM T4.00008 ABSTRACT WITHDRAWN —

4:06PM T4.00009 Bosons under an artificial staggered magnetic field in an optical ladder, MIN-CHUL CHA, IN-HO JEON, TAE-YANG AN, Department of Applied Physics, Hanyang University, Ansan, Gyeonggi-do, 426-791 Korea, CCMPL TEAM — We calculate the ground state properties of cold bosons in an frustrated optical ladder due to an artificial staggered magnetic field. By investigating the momentum distribution of bosons via a Lanczos diagonalization method, we find the signature of the transition from the Meissner to vortex states as a function of the staggering strength of the field. Various states with different frustrations are discussed.

4:18PM T4.00010 Chiral Mott insulator of kinetically frustrated bosons¹, ARUN PARAMAKANTI, University of Toronto, ARYA DHAR, Indian Institute of Astrophysics, MAHESWAR MAJI, Indian Institute of Science, TAPAN MISHRA, Indian Institute of Astrophysics, SUBROTO MUKERJEE, Indian Institute of Science, RAMESH PAI, Goa University — We study the phase diagram of the fully frustrated Bose Hubbard (FFBH) model - the presence of a π -flux through each plaquette leads to kinetic frustration for the bosons making this a nontrivial model of quantum frustration. The FFBH model is equivalent to a model of frustrated quantum XY spins, or a fully frustrated Josephson junction array where one tunes the ratio of the charging energy to the Josephson coupling. Using Monte Carlo simulations and DMRG calculations on a ladder, we show that the ground state of this model is, at intermediate correlations, a Chiral Mott insulator which supports staggered loop currents. We characterize this Mott phase as a vortex supersolid or an exciton condensate and discuss experimental observables and generalizations.

¹NSERC of Canada, CIFAR, DST (Govt of India)

4:30PM T4.00011 Mean Field Dynamics of Spin-Orbit Coupled Bose-Einstein Condensates, YONGPING ZHANG, LI MAO, CHUANWEI ZHANG, Department of Physics and Astronomy, Washington State University, Pullman, WA — We derive the mean-field Gross-Pitaevskii equation for spin-orbit coupled Bose-Einstein condensates by taking account that the pseudospin states of atoms are superpositions of the hyperfine states with different scattering lengths. The ground state phases of the condensate in a harmonic trap are obtained numerically in various parameter regions. We find a new oscillation period in the center of mass motion of the condensate subject to a sudden shift of the harmonic trap. The oscillation period is dependent on the direction of the shift of the harmonic trap, linearly proportional to the spin-orbit coupling strength, and independent on the interaction strength.

4:42PM T4.00012 Rotation of supersolids in cold atomic condensates¹, SANKALPA GHOSH, RASHI SACHDEVA, Indian Institute of Technology, Delhi — In the framework of Gross Pitaevskii equation, with non-local interaction, we study the formation of Supersolid phase and the effect of rotation on such a system. The effect of rotation is to induce vortex patterns in such Supersolid phase, whose structures are in principle, different from the ordinary vortex in Superfluids. At sufficiently high rotation, these vortices arrange in the form of a lattice and thus, one has to take into account the interplay of two lattice structures, the Supersolid crystal lattice and the vortex lattice induced by rotation. We aim to study the elastic properties of such a system and compare it with the corresponding superfluid phase.

¹Physics Department, Indian Institute of Technology, Delhi

4:54PM T4.00013 Rashbons: Emergent bosonic fermion-pairs in synthetic non-Abelian gauge fields¹, JAYANTHA P. VYASANAKERE, VIJAY B. SHENOY, Indian Institute of Science Bangalore — In presence of a synthetic non-Abelian gauge field that produces a Rashba like spin-orbit interaction, a collection of weakly interacting fermions undergoes a crossover from a BCS ground state to a BEC ground state when the strength of the gauge field is increased [PRB 84, 014512 (2011)]. The BEC that is obtained at large gauge coupling strengths is a condensate of tightly bound bosonic fermion-pairs called rashbons. This study reveals a new qualitative aspect that the rashbon state ceases to exist when the center of mass momentum of the fermions exceeds a critical value of the order of the gauge coupling strength. The study allows us to estimate the transition temperature of the rashbon BEC, and suggests a route to enhance the exponentially small transition temperature of the system with a fixed weak attraction to the order of the Fermi temperature by tuning the strength of the non-Abelian gauge field. The absence of the rashbon states at large momenta, suggests a regime in parameter space where the normal state of the system will be a dynamical mixture of uncondensed rashbons and unpaired helical fermions. Such a state should show many novel features including pseudogap physics.

¹Supported by DST and DAE, India

5:06PM T4.00014 Evolution of the structure of vortex core across the BCS-BEC crossover induced by a synthetic non-Abelian gauge field¹, NABYENDU DAS, JAYANTHA P. VYASANAKERE, VIJAY B. SHENOY, Indian Institute of Science Bangalore — We study the evolution of the structure of vortex core of fermionic superfluids with increasing strength of a non-Abelian gauge field which induces a spin-orbit interaction. Using the Bogoliubov de-Gennes formulation, we study the spectrum of core states both in the BCS limit (small gauge coupling) and in the rashbon BEC limit where the superfluid is a condensate of rashbons. We show that the novel features of rashbon dispersion, the vanishing of the bound state at finite centre of mass momentum, result in a larger core region for vortices in the rashbon BEC.

¹Supported by DST and DAE, India

5:18PM T4.00015 ABSTRACT WITHDRAWN —

Wednesday, February 29, 2012 2:30PM - 5:18PM —
Session T5 DCMP: Assembly of Atoms and Molecules in Adsorption Systems 206A

2:30PM T5.00001 Chirality Recognition and Transition Mechanism of prochiral Molecules on metals¹, YELIANG WANG, BING YANG, HUANYAO CUN, NAN JIANG, SHIXUAN DU, HONG-JUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing100190, China, K-H ERNST COLLABORATION², YUE WANG COLLABORATION³ — The self-assemble behavior of prochiral species and the induced high-order chirality by 2D confinement on solid surfaces, including (1) QA16C molecules on a Au(111) surface and (2) molecule-metallic (TPA-Fe) complex on Cu(110) as well as their transferring process will be presented. Initial stages of a chiral phase transition in the molecule monolayer on metal surfaces were investigated by scanning tunneling microscopy (STM) at submolecular resolution. The prochiral QA16C molecules form a homochiral lamella phase at low coverages upon adsorption. A transition to a racemate lattice is observed with increasing coverage. Enantiomers of a homochiral lamella line become specifically substituted by opposite enantiomers such that a heterochiral structure evolves. A "chiral replacement" model is proposed for the transition: enantiomers replace QA molecules in enantiopure phase, leading to racemic one. Our findings are significant for the understanding and control of chiral phase transitions in related molecular systems like liquid crystals.

³Jilin University, China

2:42PM T5.00002 A Library of the Nanoscale Self-Assembly of Amino Acids on Metal Surfaces, ERIN ISKI, ESMERALDA YITAMBEN, NATHAN GUISENGER, Argonne National Lab — The investigation of the hierarchical self-assembly of amino acids on surfaces represents a unique test-bed for the origin of enantio-favoritism in biology and the transmission of chirality from single molecules to complete surface layers. These chiral systems, in particular the assembly of isoleucine and alanine on Cu(111), represent a direct link to the understanding of certain biological processes, specifically the preference for some amino acids to form alpha helices vs. beta-pleated sheets in the secondary structure of proteins. Low temperature, ultra-high vacuum, scanning tunneling microscopy (LT UHV-STM) is used to study the hierarchical self-assembly of different amino acids on a Cu(111) single crystal in an effort to build a library of their two-dimensional structure with molecular-scale resolution for enhanced protein and peptide studies. Both enantiopure and racemic structures are studied in order to elucidate how chirality can affect the self-assembly of the amino acids. In some cases, density functional theory (DFT) models can be used to confirm the experimental structure. The advent of such a library with fully resolved, two-dimensional structures at different molecular coverages would address some of the complex questions surrounding the preferential formation of alpha helices vs. beta-pleated sheets in proteins and lead to a better understanding of the key role played by these amino acids in protein sequencing.

2:54PM T5.00003 Surface Patterning of Benzene Carboxylic Acids on Graphite: Influence of structure, solvent, and concentration on molecular self-assembly, GINA FLORIO, KIMBERLY STISO, JOSEPH CAMPANELLI, KIMBERLY DESSOURCES, TRUDI FOLKES, St. John's University — Scanning tunneling microscopy (STM) was used to investigate the molecular self-assembly of four different benzene carboxylic acid derivatives at the liquid/graphite interface: pyromellitic acid (1,2,4,5-benzenetetracarboxylic acid), trimellitic acid (1,2,4-benzenetricarboxylic acid), trimesic acid (1,3,5-benzenetricarboxylic acid), and 1,3,5-benzenetriacetic acid. A range of two dimensional networks are observed that depend sensitively on the number of carboxylic acids present, the nature of the solvent, and the solution concentration. We will describe our recent efforts to determine (a) the preferential two-dimensional structure(s) for each benzene carboxylic acid at the liquid/graphite interface, (b) the thermodynamic and kinetic factors influencing self-assembly (or lack thereof), (c) the role solvent plays in the assembly, (e) the effect of *in situ* versus *ex situ* dilution on surface packing density, and (f) the temporal evolution of the self-assembled monolayer. Results of computational analysis of analog molecules and model monolayer films will also be presented to aid assignment of network structures and to provide a qualitative picture of surface adsorption and network formation.

3:06PM T5.00004 Distinct Monolayer Structure of DH6T Films Grown on Untreated SiO₂¹, JOSEF SPALENKA, EHREN MANNEBACH, PHILLIP JOHNSON, University of Wisconsin-Madison, ZHONGHOU CAI, Advance Photon Source-Argonne National Laboratory, FRANZ HIMPSEL, PAUL EVANS, University of Wisconsin-Madison — Due to the relatively weak interactions between neighboring molecules, thin films of vacuum evaporated organic semiconductors can have different properties in monolayer films as compared to several monolayer and bulk-like films. We have structurally characterized monolayer and several monolayer films of dihexyl-sexithiophene (DH6T) using grazing incidence diffraction and near-edge x-ray absorption fine structure spectroscopy (NEXAFS), and electrically characterized low-coverage FET structures during deposition. The structural data indicate a distinct phase of DH6T in the monolayer which has a distorted unit cell and a distinct NEXAFS signature compared to thicker films. The hole mobility of $\sim 0.8 \text{ cm}^2/\text{V}\cdot\text{s}$ is approximately an order of magnitude higher than previously reported for vacuum deposited thick films of DH6T on unmodified SiO₂ surfaces.

3:18PM T5.00005 Nucleation of C₆₀ on ultrathin SiO₂¹, BRAD CONRAD, Appalachian State University, MICHELLE GROCE, WILLIAM CULLEN, ALBERTO PIMPINELLI, ELLEN WILLIAMS, TED EINSTEIN, University of Maryland College Park — We utilize scanning tunneling microscopy to characterize the nucleation, growth, and morphology of C₆₀ on ultrathin SiO₂ grown at room temperature. C₆₀ thin films are deposited *in situ* by physical vapor deposition with thicknesses varying from <0.05 to ~ 1 ML. Island size and capture zone distributions are examined for a varied flux rate and substrate deposition temperature. The C₆₀ critical nucleus size is observed to change between monomers and dimers non-monotonically from 300 K to 500 K. Results will be discussed in terms of recent capture zone studies and analysis methods. Relation to device fabrication will be discussed. doi:10.1016/j.susc.2011.08.020

3:30PM T5.00006 Scanning Tunneling Spectroscopy of Self-assembled Nanoribbons of C₆₀-Diamantane Hybrid Molecules, J.C. RANDEL, F.C. NIESTEMSKI, Stanford University, S. MELINTE, UCL Belgium, H.C. MANOHARAN, Stanford University — As transistors approach the nanoscale, single molecules become viable alternatives for macroscopic devices. In terms of utilizing carbon, diamondoids – single cages of the bulk diamond lattice – have recently become available as the smallest units to explore these structures. We use low temperature scanning tunneling microscopy to perform electron mapping studies on self-assembled monolayers of novel hybrid molecules consisting of a single C₆₀ fused with the double diamond cage called diamantane. Unlike standard C₆₀ self-assembled monolayers, these hybrid molecules tend to form strips or nanoribbon assemblies as opposed to large-scale single sheets. We find spectroscopic differences between these hybrid molecules and the “parent” molecule C₆₀, and utilize spatial mapping to find electronic differences in the edge states of these ribbons. We discuss these results in terms of rectification and the potential of these hybrid molecules for molecular electronics.

3:42PM T5.00007 Pentacene pinwheels: chiral heterostructures between C₆₀ and pentacene¹, JEFFREY R. GUEST, JOSEPH A. SMERDON, OZGUN SUZER, NATHAN P. GUISSINGER, Center for Nanoscale Materials, Argonne National Laboratory — Pentacene and C₆₀ are archetypal molecules for optically active acceptor-donor molecular heterojunctions and for the study of self-assembly on surfaces. Using UHV STM, we demonstrate that these molecules - despite their high degree of symmetry - can self-assemble into *chiral* heterostructures when C₆₀ is deposited on a 'random-tiling' [1] of pentacene (Pn) on Cu(111). Two different chiral heterostructures with a central C₆₀ surrounded by 6 Pns in a 'pinwheel' formation are identified: one with interlocking Pns of mixed chirality and one with shared Pns of the same chirality. The latter is observed in single chirality domains that include hundreds of pinwheels. These complex structures are solved unambiguously through the analysis of the STM images and an understanding of Pn adsorption on Cu(111) [2]. Chiral light-absorbing acceptor-donor heterojunctions may provide a powerful platform for detecting and manipulating charge, spin, and optical polarization; we will discuss the electronic properties of these structures, and the prospect for studying the interaction of these types of systems with light using our laser-STM approach.

3:54PM T5.00008 Interaction of CO₂ with Oxygen Adatoms on Rutile TiO₂(110) Surface¹, XIAO LIN, YEOHOON YOON, ZHENJUN LI, ZHI-TAO WANG, BRUCE D. KAY, IGOR LYUBINETSKY, ROGER ROUSSEAU, ZDENEK DOHNALEK, Pacific Northwest National Laboratory — On TiO₂(110), oxygen vacancies (V_O's) act as the primary catalytic sites and as such they have been extensively investigated. However, only a few studies have been reported about the interactions of adsorbates with oxygen adatoms (O_a's) that are created by O₂ dissociation in V_O's. Here, we report a combined scanning tunneling microscopy (STM) / density functional theory (DFT) study of CO₂ on bare and O_a covered TiO₂(110). STM images of TiO₂(110) surfaces obtained before and after *in-situ* dose at ~ 50 K show that CO₂ molecules preferentially adsorb next to O_a's forming CO₂/O_a complexes. Temperature dependent studies further reveal that the CO₂ binding energy next to O_a's is similar to that on V_O's. Additional CO₂ molecules are found to diffuse rapidly along the Ti row between two CO₂/O_a complexes. Due to the slow STM sampling rate the images display a time average of all CO₂ binding configurations on the Ti rows and reveal differences in the populations found on ideal Ti sites and Ti sites next to V_O's.

4:06PM T5.00009 Adsorption of CO₂ in porous MCM-41 and MCM-48 using small angle scattering¹, BO WANG, Dept. of Physics and LENS, Indiana University, NARAYAN DAS, LENS, Indiana University, GARFIELD WARREN, Dept. of Physics, Indiana University, JOHN RUPP, MARIA MASTALERZ, Indiana Geological Survey, Indiana University, TIMOTHY PRISK, PAUL SOKOL, Dept. of Physics and LENS, Indiana University, DEPARTMENT OF PHYSICS AND LOW ENERGY NEUTRON SOURCE(LENS), INDIANA UNIVERSITY TEAM, INDIANA GEOLOGICAL SURVEY, INDIANA UNIVERSITY COLLABORATION — Adsorption of CO₂ onto the surface of nanopores in organic rich materials, such as shale and coals, is of great interest for understanding the processes associated with geological sequestration. These natural materials have complex pore structures which make the interpretation of experimental sorption measurements complicated. MCMs are synthetic materials with a well-defined regular porous structure that provides an ideal substrate to evaluate the models for the adsorption of gases (CO₂) into nanopores. Samples of MCM-41 and MCM-48 were synthesized at Indiana University and were characterized by nitrogen adsorption isotherms and Small Angle X-ray Scattering (SAXS). SANS studies were carried out on MCMs with different pore sizes as a function of pore filling and the results are interpreted in terms of layer growth models.

¹Construction of LENS was supported by the NSF grants DMR-0220560 and DMR-0320627, the 21st Century Science and Technology fund of Indiana, Indiana University, and the Department of Defense. Operation of LENS is supported by Indiana University.

4:18PM T5.00010 Self-Assembly of Metal Phthalocyanine on Silicon Studied by Scanning Probe Microscopy¹, SEAN WAGNER, PENG PENG ZHANG, Michigan State University — Integration of molecular electronics into modern electronics requires an improved understanding and control of hetero-interfaces between organic molecules and semiconductor surfaces. Supramolecular assembly provides flexibility in building up complex and functional materials with nanometer scale precision over large surface areas. To study behavior at the hetero-interface, we perform supramolecular assembly of Zinc Phthalocyanine (ZnPc) on deactivated Si(111)B $\sqrt{3}\times\sqrt{3}$ and on Si(111) 7×7 . Using scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) methods both the morphology and electronic structures of the self-assembled monolayer are investigated. Molecule-molecule and molecule-substrate interactions will be discussed.

¹This work was funded by the Office of Science Early Career Research Program (DE-SC0006400) through the Office of Basic Energy Sciences, U.S. Department of Energy.

4:30PM T5.00011 Decomposition of NH₃ and H₂ on ZrB₂ (0001) surface¹, WERONIKA WALKOSZ, Materials Science Division, Argonne National Laboratory, KEDAR MANANDHAR, MICHAEL TRENARY, Department of Chemistry, University of Illinois at Chicago, PETER ZAPOL, Materials Science Division, Argonne National Laboratory — Group III nitride semiconductors (AlN, GaN, InN, and their alloys) are important materials for applications in solid-state lighting, optoelectronics, and photovoltaics. However, the lack of lattice-matched substrates for their growth results in less than optimal material quality. In the last decade, zirconium diboride (ZrB₂) has been demonstrated as a promising substrate for GaN growth because of its similar lattice constant and thermal expansion properties when compared to the nitride. Moreover, the high electrical conductivity of ZrB₂ makes it desirable for many GaN-based device applications. In this talk, we present results of density functional theory calculations for the reactivity of the ZrB₂(0001) surface towards the N precursor, NH₃, and the carrier gas, H₂, commonly used in metal organic chemical vapor deposition and molecular beam epitaxy of nitrides. Two different terminations of ZrB₂(0001) surface, the Zr and B terminations, are considered and assessed in terms of their catalytic properties toward NH₃ and H₂ decomposition. The theoretical results are analyzed in connection with our recent XPS and RAIRS measurements.

4:42PM T5.00012 Morphology of monolayer films on quasicrystalline surfaces from the phase field crystal model, JOERG ROTTLE, BENEDIKT ZIEBARTH, MICHAEL GREENWOOD, University of British Columbia — We present a computational study of the morphology of adsorbed monolayers on quasicrystalline surfaces with five- and seven-fold symmetry. The Phase Field Crystal model is employed to first simulate the growth of the quasicrystal surfaces and a two-dimensional film is then coupled elastically to the substrate. We find several different pseudomorphic phases for different types of surfaces and monolayer/substrate interactions, and quantify them by computing local order parameters. In agreement with recent experiments using colloids in quasiperiodic light fields, we find that the formation of quasicrystalline order is greatly inhibited on the seven-fold surfaces.

4:54PM T5.00013 Depolarization and bonding in quasi-one-dimensional Na structures on Cu(001), GUIDO FRATESI, ETSF, CNISM, Materials Science Department, Milano-Bicocca University, Milan, Italy — The formation of quasi-one-dimensional (Q1D) $p(n \times 2)$ -Na/Cu(001) structures is addressed by density-functional theory investigations for adsorbate coverage from low to the saturation one. A general dependence of the dipole moment on the given configuration is deduced by extending that for uniform distributions, and is greatly affecting the energetics of the Na overlayer. Larger stability for Q1D arrangements aligned along $[110]$ and $[\bar{1}\bar{1}0]$ holds at coverage larger than 0.2 ML, in agreement with low-temperature He scattering experiments, and can be explained by a reduced dipole-dipole repulsion for the $p(4 \times 2)$ with respect to hex-like distributions. Interatomic bonding charge displacements along zig-zag rows of Na atoms further support the Q1D structure and contribute significantly to the surface corrugation as seen by the He probe.

5:06PM T5.00014 Adsorption of In atoms on In/Si(111)- 8×2 studied by variable-temperature STM, HYUNGJOON SHIM, JONGHOON YEO, DONGCHUL SHIN, GEUNSEOP LEE, Department of Physics, Inha University — We have investigated adsorption of In atoms on In/Si(111) surface by using variable-temperature scanning tunneling microscope. At room temperature, the adsorbed In atoms on 4×1 are invisible due to its high mobility on a 4×1 phase. As the temperature decreases below the phase transition temperature, additional In atoms begin to appear being fixed on a 8×2 phase. The In atoms are mostly adsorbed as an isolated atoms (monomers) and paired ones (dimers) on In chains. The adsorbed In atom induces a local phase-flipping in the vicinity, resulting in a phase shift along the chain direction. Occasional hopping of isolated In atoms along the chain direction are observable at 80K. The hopping occurs preferentially in the direction of the local phase-flipping side. Formation of dimers in relation to the preferential hopping direction will be discussed.

Session T6 DMP: Focus Session: Graphene Devices - Spin, Charge, and Superconductivity

2:30PM T6.00001 Spin Relaxation and Spin Transport in Graphene , M.W. WU, Department of Physics, University of Science and Technology of China, Hefei, Anhui, 230026, China — In this talk we are going to present our theoretical investigations on spin dynamics of graphene under various conditions based on a fully microscopic kinetic-spin-Bloch-equation approach [1]. We manage to nail down the solo spin relaxation mechanism of graphene in measurements from two leading groups, one in US and one in the Netherland. Many novel effects of the electron-electron Coulomb interaction on spin relaxation in graphene are addressed. Our theory can have nice agreement with experimental data.
[1] M. W. Wu, J. H. Jiang, and M. Q. Weng, "Spin dynamics in semiconductors," Phys. Rep. **493**, 61 (2010).

3:06PM T6.00002 Spin and charge transport in high-mobility suspended graphene¹ , MARCOS GUIMARAES, PAUL ZOMER, ALINA VELIGURA, THOMAS MAASSEN, IVAN VERA-MARUN, NIKOLAOS TOMBROS, BART VAN WEES, Physics of Nanodevices, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — Recent developments in graphene device fabrication techniques have made it possible to study the intrinsic properties of graphene by removing the substrate and making it suspended. Here we report electronic spin and charge transport measurements in high-mobility (over 70 000 cm²/Vs) suspended graphene devices. To achieve this high quality we apply a large DC current density to heat the graphene flake, removing contaminations. We show that using the current annealing technique it is possible to produce ballistic nanoconstrictions, where quantized conductance at zero magnetic field is observed [N. Tombros et al., Nat. Phys. **7**, 697 (2011)]. Studying the evolution of the position of the conductance plateaus in magnetic field we determine the width of the constriction. Spin transport measurements using ferromagnetic electrodes were also performed in our suspended graphene devices [M.H.D. Guimarães et al., in preparation]. Analyzing non-local Hanle precession measurements we extract the spin relaxation time and the spin diffusion constant as a function of the charge carrier density. Combining our measurements with computer simulations we show that the measured spin relaxation times are limited by the non-cleaned regions of the device.

¹This work was financially supported by the Dutch Foundation for Fundamental Research on Matter (FOM) and NWO and realized using NanoLab.NL facilities.

3:18PM T6.00003 Conductance Quantization in Graphene Nanoconstrictions , DRAGOMIR DAVIDOVIC, CHRISTOPHER MALEC, BRADLEY ELKUS, Georgia Institute of Technology — We present measurements of conductance quantization in a narrow Graphene constriction, of approximate width 200nm. Graphene is exfoliated on top of a Silicon Dioxide, and is not suspended. In high mobility samples ($>10000\text{cm}^2\text{V}^{-1}\text{s}^{-1}$), we observe pinch-off at the Dirac point, with a resistance at 4.2K of $\sim 40\text{k}\Omega$. As a function of gate voltage at zero magnetic field, the conductance displays a few plateaus with the quantized value close to $G_0=2e^2/h$, indicating valley degeneracy splitting. At high carrier density ($>5\times 10^{12}/\text{cm}^2$) in a weak magnetic field, conductance exhibits strong beating in the Shubnikov-de Haas oscillations, which is also attributed to the valley splitting, analogous the Rashba interaction beats observed in the Shubnikov-de Haas oscillations in semiconducting quantum wells. In the Quantum Hall regime, the conductance of the constriction has quantized values $nG_0, \dots$. In comparison, measurements in the leads of the constriction display normal graphene behavior without the valley splitting.

3:30PM T6.00004 Chiral orbital current and anomalous magnetic moment in gapped graphene , MIKITO KOSHINO, Dept. of Physics, Tohoku University — We present a low-energy effective theory to describe chiral orbital current and anomalous magnetic moment in graphene monolayer and multilayers with band gap. We show that an electronic state of general Bloch system may intrinsically contain a quantum mechanical current circulation due to interband matrix elements. In gapped graphene, the current circulation is opposite between different valleys (K,K'), and the corresponding magnetic moment accounts for valley splitting of Landau levels. In gapped bilayer and ABC-stacked multilayer graphenes, in particular, the valley-dependent magnetic moment causes a huge paramagnetism at low energy, and a full valley polarization is possible up to relatively high electron density. The formulation also applies to gapped surface states of three-dimensional topological insulator, where the chiral orbital current is related to the magneto-electric response of the system.

3:42PM T6.00005 Quantum coherence versus dephasing effects in the giant spin Hall current and nonlocal voltage in magnetotransport through multiterminal graphene bridges¹ , CHIEN-LIANG CHEN, CHING-RAY CHANG, Department of Physics, National Taiwan University, Taipei 10617, Taiwan, BRANISLAV K. NIKOLIC, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716, USA — Motivated by the recent experiments [D. A. Abanin *et al.*, Science **323**, 328 (2011)] probing magnetotransport near the Dirac point in six-terminal graphene bridges from low to room temperature, we develop a nonequilibrium Green function (NEGF) theory of this phenomena. In the quantum-coherent regime, we find giant spin Hall (SH) conductance in four-terminal bridges, where the SH current is pure only at the Dirac point (DP), as well as the nonlocal voltage at a remote location in six-terminal bridges where the direct and inverse SH effect operate at the same time. The momentum-relaxing dephasing reduces their values at the DP by two orders of magnitude while washing out features away from the DP. Our theory is based on the linearized version of the Meir-Wingreen formula applied to multiterminal devices where dephasing is introduced through the self-energy within the active region of the bridge and currents and voltages are connected via generalized matrix of conductance coefficients.

3:54PM T6.00006 ABSTRACT WITHDRAWN —

4:06PM T6.00007 Magneto-transport studies of hydrogenated graphene¹ , BERNARD MATIS, National Research Council/Naval Research Laboratory, FELIPE BULAT, Sotera Defense Solutions, Inc., ADAM FRIEDMAN, BRIAN HOUSTON, JEFFREY BALDWIN, Naval Research Laboratory — We study the magnetoresistance of hydrogenated graphene devices on a SiO₂ substrate. A large negative magnetoresistance of up to 30% in a field of 2.5T is observed at low temperatures and at the film's charge neutrality point without any sign of saturation. A detailed analysis of the gate voltage dependence demonstrates a suppression of the large, negative magnetoresistance, which appears to be driven by a crossover from strong localization at low carrier concentrations to weak localization at higher carrier concentrations. Evidence of electron-hole symmetry breaking is found in the magnetic field traces at low temperature.

¹B. Matis performed this work courtesy of an National Research Council postdoctoral Fellowship. This work was supported by the Office of Naval Research.

4:18PM T6.00008 In-plane magnetotransport in gapped bilayer graphene, MATTHIAS STUDER, University of British Columbia, Canada, SIFANG CHEN, JOSHUA FOLK, University of British Columbia — The tunability of the band gap in bilayer graphene using a perpendicular electric field makes this material a promising candidate for future carbon electronics.¹ Recent studies show that the residual conductivity at low temperature in the gapped state with zero total carrier density is a result of hopping transport.² We have studied the transport in this regime as a function of an in-plane magnetic field. We find a strikingly strong positive magnetoresistance that leads to an increase of the resistance by an order of magnitude at 10 Teslas in-plane magnetic field compared to the value at 0 T. The temperature dependence of the resistance is well described by variable range hopping transport for all magnetic field values, and suggests that the hopping range is strongly dependent on the in-plane magnetic field.

4:30PM T6.00009 Direct measurements of the current-phase relation in graphene Josephson junctions, CHRISTOPHER ENGLISH, CIHAN KURTER, D.J. VAN HARLINGEN, NADYA MASON, University of Illinois at Urbana-Champaign — The current-phase relation (CPR) of a Josephson junction can provide key information about the microscopic processes and symmetries that influence the supercurrent. In this talk, we present CPR results on Josephson junctions containing single-layer graphene as a weak link. The measurements are based on a phase-sensitive SQUID technique in which we determine the supercurrent amplitude and phase as a function of both temperature and electrostatic doping (gate voltage). We present CPR measurements of narrow junctions (5 - 12 μm) in the diffusive regime spanning the temperature range of 25 - 800 mK. We compare these data with previous CPR measurements on wide junctions in the temperature range of 800 - 900 mK.

4:42PM T6.00010 Anomalous supercurrent switching in graphene under proximity e¹, ALEX LEVCHENKO, Michigan State University, U.C. COSKUN, M. BRENNER, T. HYMEL, University of Illinois at Urbana-Champaign, V. VAKARYUK, Argonne National Laboratory, A. BEZRYADIN, University of Illinois at Urbana-Champaign — We report a study of hysteretic current-voltage characteristics in superconductor-graphene-superconductor (SGS) junctions. The stochastic nature of the phase slips is characterized by measuring the distribution of the switching currents. We find that in SGS junctions the dispersion of the switching current scales with temperature as $\sigma_I \propto T^{\alpha_G}$ with $\alpha_G \approx 1/3$. This observation is in sharp contrast with the known Josephson junction behavior where $\sigma_I \propto T^{\alpha_J}$ with $\alpha_J = 2/3$. We propose an explanation using a modified version of Kurkijarvi's theory for the flux stability in rf-SQUID and attribute this anomalous effect to the temperature dependence of the critical current which persists down to low temperatures.

¹This work was supported by ONR grant N000140910689 and DOE grant DE-AC0298CH1088

4:54PM T6.00011 Gate Tuning of Different Phase-Particle Escape Regimes in Graphene-Based Josephson Junctions, GIL-HO LEE, DONGCHAN JEONG, JAE-HYUN CHOI, Dept. of Physics, POSTECH, YONG-JOO DOH, Dept. of Display and Semiconductor Physics, Korea University Sejong Campus, HU-JONG LEE, Dept. of Physics, POSTECH — Graphene-based Josephson junctions (GJJs) provide a unique system to investigate superconducting proximity effect with in-situ tunable Josephson coupling strength. While the phase-coherent behaviors of a GJJ under a magnetic field and microwave irradiation have been observed previously¹, we investigated the stochastic switching behavior of the supercurrent in this system. Here, we present the observation of the three different escaping regimes for a phase particle from a washboard potential of the GJJ; macroscopic quantum tunneling (MQT), thermal activation (TA), and phase diffusion (PD).² The crossover temperature (T_{MQT}^*) between the classical to quantum regime can be controlled by the gate voltage, implying that discrete energy levels of a phase particle are also gate-tunable. Moreover, direct observation of energy level quantization (ELQ) by microwave spectroscopy shows the consistent gate dependence of T_{MQT}^* . A new class of hybrid quantum devices such as a gate-tunable phase qubit is potentially realized by utilizing the MQT and ELQ behavior of the GJJs.

5:06PM T6.00012 Tunable resistance anomaly in graphene-superconductor hybrid structure¹, ATIKUR RAHMAN, JANICE WYNN GUIKEMA, NINA MARKOVIC, Johns Hopkins University — Junctions between superconductors and normal metals often exhibit a resistance anomaly: near the superconducting transition temperature, the resistance increases above the normal-state value. The magnitude of the excess resistance varies over a wide range, decreases in a magnetic field and can depend on the driving current and the history of thermal cycling. Several physical mechanisms have been proposed to explain the origin of the excess resistance, including the fluctuation-induced resistive state, nonequilibrium quasiparticle charge imbalance around NS boundary or phase-slip centers. Here we present an electronic transport study of superconductor-graphene hybrid structures that show a large resistance anomaly which survives even in presence of a relatively large magnetic field. We will show that, by changing the graphene resistance, we can tune the magnitude and position of the resistance peak and will examine the applicability of existing models to explain our results.

Wednesday, February 29, 2012 2:30PM - 5:06PM –
Session T7 DCOMP DMP: Focus Session: Computational Design of Materials: Electronic Structure Methods for Materials - Faster and More Accurate 207

2:30PM T7.00001 How accurate is Density Functional Theory in Predicting Reaction Energies Relevant to Phase Stability?, GEOFFROY HAUTIER, SHYUE PING ONG, ANUBHAV JAIN, CHARLES J. MOORE, GERBRAND CEDER, Massachusetts Institute of Technology — Density Functional Theory (DFT) computations can be used to build computational phase diagrams that are used to understand the stability of known phases but also to assess the stability of novel, predicted compounds. The quality and predictive power of those phase diagrams rely on the accuracy of DFT in modeling reaction energies and we will present in this talk the results of a large scale comparison between experimentally measured and DFT computed reaction energies. For starters, we will show that only certain reaction energies are directly relevant to phase stability of multicomponent systems and that very often those reaction energies are not the commonly studied reactions from the elements. Using data from different experimental thermochemical tables and DFT high-throughput computing, we will present the results of a statistical study based on more than 130 reaction energies relevant to phase stability and from binary oxides to ternary oxides. We will show that the typical error are around 30 meV/at and therefore an order of magnitude lower than the errors in reaction energies from the elements. Finally, we will discuss the broad implications of our results on the evaluation of ab initio phase diagrams and on the computational prediction of new solid phases.

2:42PM T7.00002 Correcting Density Functional Theory for Accurate Predictions of Compound Enthalpies of Formation:Fitted elemental-phase Reference Energies (FERE)¹, VLADAN STEVANOVIC, XIUWEN ZHANG, STEPHAN LANY, National Renewable Energy Laboratory, Golden CO, ALEX ZUNGER, University of Colorado, Boulder CO — The first step in the Inverse Design of materials is the assessment of their thermodynamic stability and the needed growth conditions. The compound enthalpy of formation (ΔH_f) is a quantity that provides these information. However, standard ab-initio approaches are known for their large errors in calculating ΔH_f of semiconducting and insulating compounds. In this talk I will present an approach, based on GGA+U total energies for compounds and fitted elemental-phase reference energies (FERE), that corrects GGA+U for the incomplete error cancellation between compound total energies and those of the pure elements, thereby resulting in ΔH_f values for insulating and semiconducting solids calculated with chemical accuracy. The FERE for 50 chemical elements we fit to a set of 252 measured ΔH_f of binary compounds (pnictides, chalcogenides and halides) and show accurate predictions also when applied to ternary compounds. I will discuss the application of the FERE approach in predicting new compounds, assess the accuracy of such predictions as well as comment on experimental efforts of our collaborators in growing some of the predicted materials.

2:54PM T7.00003 Correction to DFT Interaction Energies by an Empirical Dispersion Term Valid for a Range of Intermolecular Distances¹, CHRISTOS DELIGKARIS², JORGE H. RODRIGUEZ, Department of Physics, Purdue University — The computation of intermolecular interaction energies via commonly used density functionals is hindered by their inaccurate inclusion of medium and long range dispersion interactions. Computation of inter- and intra-molecule interaction energies as well as computational design of (bio)materials, requires a fairly accurate yet not overly expensive methodology. It is also desirable to compute intermolecular energies not only at their equilibrium (lowest energy) configurations but also over a range of distances. We present a method to compute intermolecular interaction energies by including an empirical correction for dispersion which is valid over a range of intermolecular distances. This is achieved by optimizing parameters that moderate the empirical correction by explicit comparison of density functional (GGA) energies with distance-dependent (DD) reference values obtained at the CCSD(T)/CBS limit. The resulting GGA-DD method yields interaction energies with an accuracy generally better than 1 kcal/mol for different types of noncovalent complexes, over a range of intermolecular distances and interaction strengths, relative to the expensive CCSD(T)/CBS standard

²Present address: Department of Physics, Drury University

3:06PM T7.00004 Accurate predictions of biomolecular interactions using density functional theory based semi-empirical alchemical derivatives in chemical compound space, ANATOLE VON LILIENFELD, Argonne National Laboratory — A small but relevant sub-set of chemical compound space is explored in terms of biomolecular interaction energies, and using analytical derivatives. When transmutating any two iso-electronic ligands their intermolecular energies are not necessarily monotonic functions, consequently the corresponding Hellmann-Feynman derivatives can fail to predict the right trends. Semi-empirical corrections, effectively linearizing the intermolecular energy in the interpolation parameter, promise to drastically improve the predictive power of these first order derivatives. For various biomolecules, including ellipticine interacting with DNA, we show that these semi-empirical derivatives yield predictions superior to alternative prediction schemes that are additive and derivative-free. As such, new evidence is presented in support of the conclusion that quantitative estimates of relevant properties of new molecules can be made without additional self-consistency calculations.

3:18PM T7.00005 Preliminary results in data mining for materials¹, DA GAO, YOUSEF SAAD, University of Minnesota at Twin Cities, JAMES CHELIKOWSKY, University of Texas at Austin — In recent years, materials scientists have started exploiting data mining techniques, i.e., methods for extracting meaningful information and patterns from data, for the discovery and design of materials. One of the grand challenges in this methodology is to establish correlations and intrinsic features in materials database in order to facilitate the extraction of useful information that can be exploited to discover new hypothetical materials. Using an atomic properties database of 110 elements, obtained from quantum mechanical calculations and several macroscopic properties database of binary compounds, we explored several sample data mining techniques to study the correlations among them with the goal of predicting macroscopic properties from knowledge of the atomic constituents. In this talk, preliminary results of such efforts will be presented to demonstrate how simple data mining can be applied in materials science and what they can achieve. These preliminary results indicate a good potential for data mining applications in materials science.

¹We would like to acknowledge support from the National Science Foundation under grants No. DMS-0810938, DMR-0940218, DMR-0941645 and OCI-1047997 and from the Welch Foundation under grant No. F-1708.

3:30PM T7.00006 Expediting Solutions for the Electronic Structure of Large Systems: A Spectrum Slicing Algorithm¹, GRADY SCHOFIELD, JAMES CHELIKOWSKY, University of Texas, YOUSEF SAAD, University of Minnesota — Solving the Kohn-Sham equation requires computing a set of low lying eigenpairs. The standard methods for computing such eigenpairs require two procedures: (a) maintaining the orthogonality of an approximation space, and (b) forming approximate eigenpairs with the Rayleigh-Ritz method. These two procedures scale cubically with the number of desired eigenpairs. We present a method, applicable to *any* large Hermitian eigenproblem, by which the spectrum is partitioned among distinct groups of processors. This “divide and conquer” approach serves as a parallelization scheme at the level of the solver, making it compatible with existing schemes that parallelize at a physical level, *e.g.*, k-points or symmetric representations, and at the level of primitive operations, matrix-vector multiplication. In addition, among all processor sets, the size of any approximation subspace is reduced, thereby reducing the cost of orthogonalization and the Rayleigh-Ritz method. We will explain the key aspects of the algorithm that give reliability, and demonstrate the accuracy of the algorithm by computing the electronic structure of a core-shell nanocrystal and a DNA segment. Overall scaling and the utility of the method for a wide variety of applications will be discussed.

¹We wish to acknowledge support from the National Science Foundation under grants No. DMR-0941645 and OCI-1047997 and from The Welch Foundation under grant No. F-1708.

3:42PM T7.00007 Density Functional Theory using Multiresolution Analysis with MADNESS, SCOTT THORNTON, ROBERT HARRISON, Joint Institute for Computational Sciences — We describe the first implementation of the all-electron Kohn-Sham density functional periodic solver (DFT) using multi-wavelets and fast integral equations using MADNESS (multiresolution adaptive numerical environment for scientific simulation; <http://code.google.com/p/m-a-d-n-e-s-s/>). The multiresolution nature of a multi-wavelet basis allows for fast computation with guaranteed precision. By reformulating the Kohn-Sham eigenvalue equation into the Lippmann-Schwinger equation, we can avoid using the derivative operator which allows better control of overall precision for the all-electron problem. Other highlights include the development of periodic integral operators with low-rank separation, an adaptable model potential for the nuclear potential, and an implementation for Hartree-Fock exchange.

3:54PM T7.00008 GPU speedup of the plane wave pseudopotential density functional theory calculations¹, LIN-WANG WANG, Material Science Division, Lawrence Berkeley National Lab, Berkeley, CA, 94720, WEILE JIA, ZONGYAN CAO, LONG WANG, XUEBIN CHI, Supercomputing Center, Computer Network Information Center, Chinese Academy of Sciences, Beijing, China, WEIGUO GAO, School of Mathematical Sciences, Fudan University, Shanghai, China — Plane wave (PW) pseudopotential density functional theory (DFT) calculation is the most widely used method for computational design of new materials. In this talk, we will present our recent work in using the graphics processing unit (GPU) to accelerate the PW-DFT calculations. Compared with the pure CPU calculation, the GPU machine with CUDA coding can speed up the calculation by 20 times for systems with a few hundred atoms, while still being able to scale to hundreds of CPU/GPU units. However, to reach this speedup, some algorithm changes are necessary. We will discuss these algorithm changes, and various computational kernels in a PW-DFT code, and their speedups in the GPU code. These include the FFT, the nonlocal projector, the orthogonalization and the diagonalization. We will also discuss the computational times for MPI communication, CPU/GPU memory copy, and floating point operation. We will present the hardware and library requirement to further speed up the calculations. Finally, the implication of the GPU speed up for new material design will be discussed.

¹This work is supported by SC/BES of U.S. Department of Energy under Contract No. DE-AC02-05CH11231, and NSF of China.

4:06PM T7.00009 Linear-scaling DFT+U applied to hole localization and Friedel oscillations in very dilute (Ga,Mn)As, ARASH MOSTOFI, Imperial College London, DAVID O'REGAN, Swiss Federal Institute of Technology Lausanne (EPFL), NICHOLAS HINE, Imperial College London, MICHAEL PAYNE, University of Cambridge — System-size and strong electronic correlation are two factors inhibiting the routine first-principles simulation of transition-metal doped nanostructures. Tackling these issues simultaneously, we have developed a linear-scaling implementation of the DFT+U method within the ONETEP code,¹ demonstrating scaling upto 7,000 atoms. Our implementation allows for nonorthogonal projectors,² which may be self-consistently optimized.³ We apply our approach to the prototypical dilute magnetic semiconductor (Ga,Mn)As. The ferromagnetic interaction between distant localized magnetic moments in (Ga,Mn)As is mediated by defect-induced holes, whose long-range character is critical. Our large-scale calculations on 1,728 atom super-cells enable us to study the localization and symmetry of the magnetization and hole in the very dilute (0.1%) limit, and to analyze the long-range Friedel oscillations.

4:18PM T7.00010 G0W0 implementation using Lanczos algorithm and Sternheimer equation, JONATHAN LAFLAMME JANSSEN, NICOLAS BERUBE, GABRIEL ANTONIUS, MICHEL COTÉ, University of Montreal — The G0W0 approach is an accurate method to give a physical meaning to the eigenvalues obtained in density-functional theory (DFT) calculation. However, the calculation of such corrections with plane wave codes is currently prohibitive for systems with more than a few hundreds of electrons. What limits calculations to this system size is the need in current implementations to invert the dielectric matrix and the need to carry out summations over conduction bands. This talk presents a strategy to avoid both of these bottlenecks. In traditional plane wave implementations of G0W0, the dielectric matrix is expressed in a plane wave basis, which needs to be relatively big to properly describe the matrix. Here, we will explain how a Lanczos basis can be generated to substantially reduce the size of the matrix. Also, the number of conduction bands needed to reach convergence in the summations is usually an order of magnitude larger than the number of valence bands. Here, the calculation of the conduction states is avoided by reformulating the summations into linear equation problems (Sternheimer equations), which also substantially reduces the computation time. Preliminary results will be presented.

4:30PM T7.00011 Dynamical Cluster Approximation: Cluster Extension of CPA for Disordered System¹, CHINEDU EKUMA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, WEI KU, TOM BERLIJN, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York, 11973, USA, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA — The dynamical mean-field approximation (DMFA) or the coherent potential approximation (CPA) provides a convenient and effective method for studying disordered systems; however, non-local short range correlations of the disorder potential are neglected leading to a self-consistent single-site approximation. We combine the recently developed first principles method of Wei Ku and co-workers for the simulation of disordered systems with the dynamical cluster approximation (DCA) to develop a highly efficient means to treat disordered systems. We solve this model system using the DCA, which systematically incorporates short-range nonlocal correlations to the CPA. We apply this method to a number of model systems to illustrate where the DCA or a finite size simulation is more appropriate.

4:42PM T7.00012 Analyzing electron-electron correlations at nanoscale: a DFT+DMFT code for nanosystems¹, VOLODYMYR TURKOWSKI, ALAMGIR KABIR, TALAT S. RAHMAN, Physics Department and NSTC, University of Central Florida — We propose a DFT+DMFT approach to study electron-electron correlation effects in nanosized systems containing atoms with localized d- and f-electron states. For the purpose we have developed a nanoDFT+DMFT code which allows one to study the properties of systems containing up to several hundred atoms. The system geometry is first optimized using ab-initio electron structure calculations based on density-functional theory (DFT), and correlation effects are analyzed employing nonhomogeneous Dynamical Mean-Field Theory (DMFT) calculations with the iterated perturbation theory (IPT) approximation for the quantum impurity solver. To test the formalism we have evaluated the magnetic properties of several transition metal atom clusters and compared the results with those obtained from the exact diagonalization method (a few-atom clusters) and available experimental data (2-19 atom clusters). In particular, we find that the IPT-DMFT gives magnetic moments much closer to experimental values as compared to DFT calculations. We discuss possible extensions of the approach including application of more accurate quantum impurity solvers, such as Hirsch-Fye and Continuous-Time Quantum Monte Carlo. The application of the methodology to the nonequilibrium case is in progress.

4:54PM T7.00013 Using Machine Learning to Accelerate Complex Atomic Structure Elucidation, WILLIAM BROUWER, LAZARO CALDERIN, JORGE SOFO, The Pennsylvania State University — Workers in various scientific disciplines seek to develop chemical models for extended and molecular systems. The modeling process revolves around the gradual refinement of model assumptions, through comparison of experimental and computational results. Solid state Nuclear Magnetic Resonance (NMR) is one such experimental technique, providing great insight into chemical order over Angstrom length scales. However, interpretation of spectra for complex materials is difficult, often requiring intensive simulations. Similarly, working forward from the model in order to produce experimental quantities via ab initio is computationally demanding. The work involved in these two significant steps, compounded by the need to iterate back and forth, drastically slows the discovery process for new materials. There is thus great motivation for the derivation of structural models directly from complex experimental data, the subject of this work. Using solid state NMR experimental datasets, in conjunction with ab initio calculations of measurable NMR parameters, a network of machine learning kernels are trained to rapidly yield structural details, on the basis of input NMR spectra. Results for an environmentally relevant material will be presented, and directions for future work.

Wednesday, February 29, 2012 2:30PM - 5:30PM – Session T8 DMP GMAG: Focus Session: Helical Phases and Skyrmions 208

2:30PM T8.00001 Spin waves in a skyrmion crystal¹, OLGA PETROVA, OLEG TCHERNYSHYOV, Johns Hopkins University — We derive the spectrum of low-frequency spin waves in skyrmion crystals observed recently in noncentrosymmetric ferromagnets [1-4]. We treat the skyrmion crystal as a superposition of three helices whose wavevectors form an equilateral triangle [1]. The low-frequency spin waves are Goldstone modes associated with displacements of skyrmions. Their dispersion is determined by the elastic properties of the skyrmion crystal and by the kinetic terms of the effective Lagrangian, which include both kinetic energy and a Berry phase term reflecting a non-trivial topology of magnetization. The Berry phase term acts like an effective magnetic field, mixing longitudinal and transverse vibrations into a gapped cyclotron mode and a twist wave with a quadratic dispersion [5].

2:42PM T8.00002 Skyrmion contribution to thermopower of MnSi, ANA AKRAP, Department of Condensed Matter Physics, University of Geneva, CH-1211 Geneva 4, Switzerland, STEVAN ARSENIJEVIĆ, Institute of Condensed Matter Physics, Swiss Federal Institute of Technology, EPFL, CH-1015 Lausanne, Switzerland, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, New York 11973, USA, LÁSZLÓ FORRÓ, Institute of Condensed Matter Physics, Swiss Federal Institute of Technology, EPFL, CH-1015 Lausanne, Switzerland — Skyrmions have recently been theoretically predicted [1] and experimentally observed [2] in MnSi. To identify whether skyrmions contribute to thermoelectric transport, we present a detailed map of the temperature, pressure and magnetic field behavior of thermopower S in MnSi. $S/T(p, T)$ confirms the established phase diagram with Fermi liquid, non-Fermi liquid and partial order phases. In the high pressure non-Fermi liquid phase, $S(T)$ increases in the vicinity of the boundary with the Fermi liquid phase, at critical pressure $p_c \sim 14.5$ kbar. This may be linked to the scattering of conduction electrons on fluctuating amorphous skyrmions [1]. On the contrary, the thermopower decreases when an ordered lattice of skyrmions is established in the magnetic field. A small suppression of $S(T)$ is observed in a narrow region, for $27 \text{ K} < T < 29 \text{ K}$, and $0.1 \text{ T} < B < 0.3 \text{ T}$, corresponding to the ordered skyrmion A phase.

2:54PM T8.00003 Quantum order-by-disorder near criticality and the secret of the partially ordered phase of MnSi, FRANK KRUGER, UNA KARAHASANOVIC, University of St Andrews, ANDREW GREEN, University College London — The vicinity of quantum phase transitions has proven fertile ground in the search for new quantum phases. We propose a physically motivated and unifying description of the phase reconstruction near metallic quantum-critical points using the idea of quantum order-by-disorder. Certain deformations of the Fermi surface associated with the onset of competing order enhance the phase space available for low-energy, particle-hole fluctuations and self-consistently lower the free energy. Applying the notion of quantum order-by-disorder to the itinerant helimagnet MnSi, we show that near to the quantum critical point, fluctuations lead to an increase of the spiral ordering wave vector and a reorientation away from the lattice favoured directions. The magnetic ordering pattern in this fluctuation-driven phase is found to be in excellent agreement with the neutron scattering data in the partially ordered phase of MnSi.

3:06PM T8.00004 Density-functional electronic structure and the origin of the Dzyaloshinskii-Moriya spin interaction in MnSi, K.V. SHANAVAS, S. SATPATHY, Department of Physics & Astronomy, University of Missouri — The metallic helimagnet MnSi has been found to exhibit skyrmionic spin textures when subjected to magnetic fields at low temperatures. The Dzyaloshinskii-Moriya (DM) interaction plays a key role in stabilizing the skyrmions, which arises from the anisotropic part of the super-exchange coupling and is of the form $\vec{D} \cdot (\vec{S}_i \times \vec{S}_j)$. The constant $\vec{D}$ depends on the strength of spin-orbit interaction of Mn d states and the orbital mixing induced by the distortion of MnSi₆ octahedra from the centrosymmetric rock salt phase. Using density functional theory based electronic structure calculations and symmetry analysis, we study the nature of the electronic ground state and the origin of the DM interaction in the B20 phase of MnSi. The ground state in the undistorted phase corresponds to d^6 configuration at Mn and p^2 at Si sites. The distortion reduces bandwidths and intermixes the ground state with the excited states, leading to a significant DM spin-orbit interaction.

3:18PM T8.00005 Criticality Induced First-Order Phase Transition in Dzyaloshinskii-Moriya Helimagnets, MARC JANOSCHEK¹, Los Alamos National Laboratory, MARKUS GARST, Universitaet zu Köln, ANDREAS BAUER, Technische Universitaet Muenchen, PASCAL KRAUTSCHEID, Universitaet zu Köln, ROBERT GEORGII, FRM II Technische Universitaet Muenchen, PETER BOENI, CHRISTIAN PFLEIDERER, Technische Universitaet Muenchen — Almost two centuries of research on phase transitions have repeatedly highlighted the importance of critical phenomena. One fascinating implication of critical phenomena is that critical fluctuations may drive the associated phase transition first order if symmetry allows them to assume enough phase space. As discussed by Brazovski, this is in particular the case if critical fluctuations become soft on a sphere in momentum space. By means of combined specific heat, magnetic susceptibility and neutron scattering measurements of the model helimagnet MnSi we show that this scenario is realized for the helimagnetic phase transition in Dzyaloshinskii-Moriya(DM) helimagnets with weak magnetic anisotropy. The remarkable agreement observed between experiment and theory clarifies the longstanding issue of the nature of the helimagnetic transition in MnSi, but more importantly, our calculations are entirely based on symmetry arguments, making this result relevant to DM helimagnets in general. This is in particular noteworthy in the light of a series of new discoveries that show that DM helimagnetism is at the heart of problems such as topological magnetism, multiferroics, and spintronics.

3:30PM T8.00006 Tricriticality and giant magneto-elasticity in CoMnSi¹, KARL SANDEMAN, ZSOLT GERCSI, Imperial College London, ALEX BARCZA, University of Cambridge, KEVIN KNIGHT, ISIS, Rutherford Appleton Laboratory — Tricritical magnets have previously facilitated the study of different critical phenomena and scaling laws by varying external parameters (pressure, field and temperature) instead of composition. We have studied tricritical magnets driven by interest in the enhanced magnetocaloric effects seen at the first order side of a tricritical point where hysteresis can be minimised. Here we describe the results of microcalorimetry, Hall probe imaging, dilatometry, magnetometry and neutron diffraction experiments and density functional calculations. We build a picture of the relation between structure and magnetism in CoMnSi and find a giant magneto-elasticity that underpins the evolution of first order behavior in this metamagnetic helical antiferromagnet [2]. We are then able to use density functional theory to predict new metamagnets based on this insight. These have been successfully synthesized [3].

3:42PM T8.00007 Hall effect of spin-chirality origin in a triangular-lattice helimagnet Fe_{1.3}Sb, YUKI SHIOMI, MASAHIITO MOCHIZUKI, Department of Applied Physics, University of Tokyo, YOSHIO KANEKO, Multiferroics Project, ERATO, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo — We report on a topological Hall effect possibly induced by scalar spin chirality in a quasi-two-dimensional helimagnet Fe_{1+x}Sb. In the low-temperature region where the spins on interstitial-Fe (concentration $x \approx 0.3$) intervening the 120° spin-ordered triangular planes tend to freeze, a non-trivial component of Hall resistivity with opposite sign of the conventional anomalous Hall term is observed under magnetic field applied perpendicular to the triangular-lattice plane. The observed unconventional Hall effect is ascribed to the scalar spin chirality arising from the heptamer spin-clusters around the interstitial-Fe sites, which can be induced by the spin modulation by the Dzyaloshinsky-Moriya interaction.

3:54PM T8.00008 Vortex walls in helical magnets¹, FUXIANG LI, Dept. Physics and Astronomy, Texas A&M University, THOMAS NATTERMANN, Inst. Of Theoretical Physics, University of Cologne, D-50937, Cologne, Germany, VALERY POKROVSKY², Dept. Physics and Astronomy, Texas A&M University — The structure of domain walls determines to a large extent the properties of magnetic materials, in particular their hardness and switching behavior, it represents an essential ingredient of spintronics. In Bloch and Neel domain walls the magnetization rotates around a fixed axis in a one-dimensional magnetization profile. Surprisingly, domain walls in helical magnets, most relevant in multiferroics and metals, were never studied. We show that domain walls in helical magnets are fundamentally different from Bloch and Neel walls. They are generally two-dimensional patterns formed by a regular lattice of vortex singularities. Only at discrete exceptional orientations, domain walls are free of vortices, but still remain two-dimensional textures. In helical magnets with weak anisotropy the domain wall width and energy only weakly depend on the anisotropy, though domain wall does not exist without it. In conical phases vortices carry Berry phase flux resulting in the anomalous Hall effect. In multiferroics vortices are electrically charged allowing manipulating magnetic domain walls by the electric field. Our theory allows the interpretation of magnetic textures observed in helical magnetic structures.

4:06PM T8.00009 Spin scalar chiral ordering and hidden positive biquadratic interaction in frustrated Kondo lattice systems, YUTAKA AKAGI, Dept. of Appl. Phys., Univ. of Tokyo, MASAFUMI UDAGAWA, Dept. of Appl. Phys., Univ. of Tokyo, MPI PKS, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Recently, noncoplanar spin configurations with spin scalar chirality have drawn considerable attention as an origin of the anomalous Hall effect. In this mechanism, itinerant electrons acquire an internal magnetic field according to the solid angle spanning three spins through the so-called Berry phase, which can result in the anomalous Hall effect. In order to explore such nontrivial magnetic states in spin-charge coupled systems, we investigate a ferromagnetic Kondo lattice model on a triangular lattice by variational and perturbative calculations. As a result, we find that a noncoplanar four-sublattice spin ordering emerges near 1/4 filling, in addition to the 3/4 filling reported in the previous study. This new phase is stabilized in a wider parameter region compared to the 3/4 filling phase [1]. We also find that a kinetic-driven positive biquadratic interaction is critically enhanced and plays a crucial role on stabilizing a spin scalar chiral ordering near 1/4 filling. The origin of large positive biquadratic interaction is ascribed to the Fermi surface connection by the four sublattice ordering wave vectors, which we call the higher-order Kohn anomaly [2]. [1] Y. Akagi and Y. Motome, *J. Phys. Soc. Jpn.* **79** (2010) 083711. [2] Y. Akagi, M. Udagawa, and Y. Motome, submitted.

4:18PM T8.00010 First Principles Calculation of Helical Spin Order in Iron Perovskite SrFeO₃ and BaFeO₃, ZHI LI, Yukawa Institute for Theoretical Physics, Kyoto University — Motivated by recent discovery of ferromagnetism in cubic perovskite BaFeO₃ under small magnetic field, we investigate spin order in BaFeO₃ and isostructural SrFeO₃ by a first principles calculation using local spin density approximation (LSDA). We find that on-site Coulomb interaction U is necessary for obtaining helical spin order consistent with experiments. SrFeO₃ exhibits G-type helical order, while BaFeO₃ exhibits the A-type with very small wave vector. The A-type order is stabilized by lattice expansion. Small energy difference between the A-type and ferromagnetic orders explains ferromagnetism under small field. The LSDA+ U results are consistent with model calculation where negative charge-transfer energy in these compounds is explicitly taken into account.

4:30PM T8.00011 Investigation of the role of spin-texture on the Na_{0.46}CoO₂, J.W. KIM, E.-D. MUN, R. McDONALD, J. THOMPSON, I. MARTIN, C. BATISTA, V. ZAPF, LANL, P. MOLL, ETH-Zurich, A. MORPURGO, University of Geneva, D. ARGYRIOU, Helmholtz-Zentrum Berlin für Materialien und Energie — We will present magnetotransport properties and their relationship to a possible chiral spin texture in ultra-thin Na_{0.46}CoO₂ devices in high magnetic fields. This composition exhibits a weakly insulating state, with a frustrated local spin texture, unique, among the hexagonal Na_xCoO₂ family. Previous a large Hall effect was found for composition $x=0.5$ (M. Foo *et al.*, Phys. Rev. Lett. 92, 247001 (2004)) and prior high-field studies (L. Balicas *et al.*, Phys. Rev. Lett. 94, 236402 (2005).) have found the existence of a small Fermi surface in the system and a two-fold angular magnetoresistance. To date however, the Hall-conductivity has not been investigated in magnetic fields strong enough to suppress the charge-order, above 41 T. Herein, we investigate the role of local spin-texture (in the charge-ordered state) on the Hall conductance by measuring both bulk and devices with only several monolayers thick in strong magnetic fields. Our investigations under magnetic fields ($B < 60$ T) show that the high resistivity charge-order region is suppressed with out-of-plane field at $B \sim 41$ T with highly non-monotonic $-\rho_{xy}$ with a maximum at $B \sim 27$ T and rapidly decreases to zero. However, magnetization measurements show no significant features within measurement accuracy indicating that magnetization changes are small at the field-induced phase transition. Recent theoretical advances suggest that this compound exhibits a quantum Hall state coupled with spin chirality (I. Martin, C. D. Batista, Phys. Rev. Lett. 101, 156402 (2008)).

4:42PM T8.00012 Spin spiral state in hexagonal NiS¹, RAQUEL LIZARRAGA², ERIK HOLMSTROM³, Instituto de Ciencias Físicas y Matemáticas, LARS NORDSTROM⁴, OLLE ERIKSSON⁵, Department of Physics and Astronomy, SWARUP PANDA⁶, INDRA DASGUPTA⁷, D.D. SARMA⁸, Indian Institute of Science — Previous nesting function calculations on NiS have found instabilities for the magnetic ordering vectors $q=(2/3,2/3,0)$ and $q=(1/2,2/9,1)$ suggesting that the magnetic structure of NiS is non-collinear which does not agree with the experimentally determined antiferromagnetic state. We investigated the electronic and magnetic structure of NiS by means of a full-potential linearized augmented plane wave method within the local spin density approximation plus the Hubbard parameter U . Our method is specially suitable to study noncollinear magnetism where the magnetization density is allowed to vary in magnitude and direction continuously everywhere in space. Our results show that the ground state is metallic and that the antiferromagnetic state is almost degenerate with spin spirals along certain directions of the Brillouin zone.

4:54PM T8.00013 Incommensurate antiferromagnetism in GdSi, YEJUN FENG, Argonne National Lab, JIYANG WANG, Univ. of Chicago, J.-W. KIM, Argonne National Lab, J.-Q. YAN, Univ. Tennessee & ORNL, NAYOON WOO, D.M. SILEVITCH, T.F. ROSENBAUM, Univ. of Chicago — Rare earth magnets are interesting model systems to study correlated spin, orbital and lattice degrees of freedom. Here we present a study of the antiferromagnetism in single crystal GdSi, using high-resolution, x-ray magnetic diffraction techniques. Our results clearly show an incommensurate magnetic structure at 6.5 K, with a lattice distortion from orthorhombic to monoclinic accompanying the magnetic phase transition in a second order fashion. We discuss implication to the anisotropic susceptibility in lights of the detailed magnetic structure.

5:06PM T8.00014 Spin-Orbital Locking, Emergent Pseudo-Spin, and Magnetic order in Na₂IrO₃, SUBHRO BHATTACHARJEE¹, University of Toronto, SUNG-SIK LEE², McMaster University, YONG BAEK KIM³, University of Toronto — The nature of magnetic order in the honeycomb lattice Iridate Na₂IrO₃ is explored by considering trigonal crystal field effect and spin-orbit coupling. An effective Hamiltonian is derived in terms of an emergent pseudo-spin-1/2, resulting from a spin-orbital locking, which is different from $j_{\text{eff}} = 1/2$ that is obtained when the spin-orbit coupling dominates. The resulting Hamiltonian is anisotropic and frustrated. Mean field theory suggests a ground state with 4-sublattice zig-zag magnetic order in the relevant parameter regime, in conformity with experiments. Various properties of the phase, the spin-wave spectrum and experimental consequences are discussed. Our approach contrasts with the recent proposal of a Heisenberg-Kitaev system for this material, and we point out the intrinsic difficulties with the latter approach for describing the magnetic properties of Na₂IrO₃.

5:18PM T8.00015 Magnetic order on a frustrated lattice due to orbital degrees of freedom in RO₂ hyperoxides¹, ANDRZEJ M. OLEŚ, Jagellonian University, Cracow, Poland, KRZYSZTOF WOHLFELD, MARIA DAGHOFER, IFW Dresden, Germany — The alkali RO₂ hyperoxides ($R=\text{Rb,Cs,K}$) crystallize in a frustrated bct lattice. Nevertheless, all of the members of the family of alkali RO₂ hyperoxides have long range layered C -type antiferromagnetic (C -AF) order at low temperature. We show that including the almost degenerate p -orbital degrees of freedom in a realistic spin-orbital model can resolve this contradiction [1]. Although *a priori* the orbital degrees of freedom do not remove frustration in spin system, we show that the anomalously large interorbital hopping together with the orbital order induced by the lattice stabilize the C -AF order in this class of compounds, in agreement with generalized Goodenough-Kanamori rules formulated here.

Session T9 GMAG DMP: Focus Session: Magnetic Oxide Thin Films And Heterostructures - Interactions at Interfaces and in Superlattices 209

2:30PM T9.00001 Upper limit to magnetism in $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures, MICHAEL FITZSIMMONS, Los Alamos National Laboratory — In 2004 Ohtomo and Hwang reported unusually high conductivity in LaAlO_3 and SrTiO_3 bilayer samples. Since then, metallic conduction, superconductivity, magnetism, and coexistence of superconductivity and ferromagnetism have been attributed to $\text{LaAlO}_3/\text{SrTiO}_3$ interfaces. Very recently, two studies have reported large magnetic moments attributed to interfaces from measurement techniques that are unable to distinguish between interfacial and bulk magnetism. Consequently, it is imperative to perform magnetic measurements that by being intrinsically sensitive to interface magnetism are impervious to experimental artifacts suffered by bulk measurements. Using polarized neutron reflectometry, we measured the neutron spin dependent reflectivity from four $\text{LaAlO}_3/\text{SrTiO}_3$ superlattices. Our results indicate the upper limit for the magnetization averaged over the lateral dimensions of the sample induced by an 11 T magnetic field at 1.7 K is less than 2 G. SQUID magnetometry of the neutron superlattice samples sporadically finds an enhanced moment (consistent with past reports), possibly due to experimental artifacts. These observations set important restrictions on theories which imply a strongly enhanced magnetism at the interface between LaAlO_3 and SrTiO_3 . Work performed in collaboration with N.W. Hengartner, S. Singh, M. Zhernenkov (LANL), F.Y. Bruno, J. Santamaria (Universidad Complutense de Madrid), A. Brinkman, M.J.A. Huijben, H. Molegraaf (MESA+ Institute for Nanotechnology), J. de la Venta and Ivan K. Schuller (UCSD).

3:06PM T9.00002 Magnetotransport behavior in $(\text{LaNiO}_3)_n/(\text{LaMnO}_3)_2$ superlattices, JASON HOFFMAN, Materials Science Division, Argonne National Laboratory, ANAND BHATTACHARYA, Materials Science Division and Center for Nanoscale Materials, Argonne National Laboratory — Recent advances in the deposition of epitaxial complex oxides have enabled the fabrication of a wide range of materials structures with atomically abrupt interfaces, that are characterized by novel electronic and magnetic ground states. In particular, superlattices that combine the paramagnetic metal, LaNiO_3 , with various band insulators, such as SrTiO_3 and LaAlO_3 , have attracted considerable theoretical and experimental interest. In this work, $(\text{LaNiO}_3)_n/(\text{LaMnO}_3)_2$ ($2 \leq n \leq 5$) superlattices that combine LaNiO_3 with an antiferromagnetic insulator are prepared on (001) SrTiO_3 substrates using ozone-assisted oxide molecular beam epitaxy. The total superlattice thickness is fixed at ~ 30 nm. X-ray reflectivity and x-ray diffraction reveal single-crystalline growth with interfacial and surface roughnesses of ~ 0.2 nm and ~ 0.5 nm, respectively. Electrical transport measurements carried out on superlattices with $n \leq 3$ show insulating behavior between 5 K and 300 K, while samples with $n = 4, 5$ are metallic with resistivity minima at 90 K and 30 K, respectively, below which we observe negative magnetoresistance. We discuss the role of charge transfer between LaNiO_3 and LaMnO_3 in understanding these results.

3:18PM T9.00003 Confinement induced metal-to-insulator transition in strained $\text{LaNiO}_3/\text{LaAlO}_3$ superlattices¹, ARIADNA BLANCA ROMERO, Ludwig Maximilians University Munich, Germany, ROSSITZA PENTCHEVA, Ludwig Maximilians University Munich — Using density functional theory calculations including a Hubbard U term we explore the effect of strain and confinement on the electronic ground state of superlattices containing the band insulator LaAlO_3 and the correlated metal LaNiO_3 . Besides a suppression of holes at the apical oxygen, a central feature is the asymmetric response to strain in single unit cell superlattices: For tensile strain a band gap opens due to charge disproportionation at the Ni sites with two distinct magnetic moments of $1.45\mu_B$ and $0.71\mu_B$. Under compressive strain, charge disproportionation is nearly quenched and the band gap collapses due to overlap of $d_{3z^2-r^2}$ bands through a semimetallic state. This asymmetry in the electronic behavior is associated with the difference in octahedral distortions and rotations under tensile and compressive strain. The ligand hole density and the metallic state are quickly restored with increasing thickness of the $(\text{LaAlO}_3)_n/(\text{LaNiO}_3)_n$ superlattice from $n = 1$ to $n = 3$.

¹We acknowledge support from the German Science Foundation, SFB/TR80.

3:30PM T9.00004 Electronic structure, charge modulation, and orbital polarization of $\text{LaNiO}_3/\text{SrTiO}_3$ superlattice¹, MYUNG JOON HAN, MICHEL VAN VEENENDAAL, Argonne National Lab and Northern Illinois University — First-principles density functional theory calculations have been performed to understand the detailed electronic structure for the various (m, n) combinations of $(\text{LaNiO}_3)_m/(\text{SrTiO}_3)_n$ superlattices. Due to the strong covalency of Ni-O bonds, the valence bands are dominated by Ni-d character and the electronic structure is mainly affected by the local environment rather than the ionic potential. Heterostructuring-induced quantum states and the interaction between them leads to the charge redistribution around the Fermi level, which may be responsible for the charge modulation and metal-insulator transition observed in the related systems.

¹This work was supported by the US Department of Energy (DOE) under Contract No. DE- FG02-03ER46097

3:42PM T9.00005 Electronic, magnetic, and structural coupling across oxide interfaces, CHARLES AHN, Yale University — Many complex oxide materials exhibit a strong interplay between spin, charge, and lattice effects. This coupling leads to a variety of novel electronic and magnetic properties, including charge ordered and magnetic states, “colossal” magnetoresistance (CMR), and a range of electron transport behavior. The possibility of integrating these different kinds behavior with other types of functionalities has motivated the development of new, artificially structured complex oxide-based materials systems, such as composite multiferroic heterostructures. In certain cases, the atomic-scale interface of these structures can dominate the observed behavior, with new physical properties emerging. For example, in epitaxial ferromagnetic/ferroelectric heterostructures, it is possible to achieve large magnetoelectric coupling that is controlled directly by the charge degrees of freedom. We have studied this coupling using a variety of techniques, including magnetization, magneto-optic Kerr effect magnetometry, and x-ray absorption spectroscopy. In addition, structural distortions that arise exclusively at the interface can influence simultaneously the interfacial electronic transport and magnetic properties. Using high resolution synchrotron scattering, we have determined the interplay between new interfacial structural motifs and the resulting electronic and magnetic function at the interface.

4:18PM T9.00006 Ferroelectric control of magnetocrystalline anisotropy and orbital magnetism in thin-film Fe/BaTiO_3 heterostructures, PAVEL LUKASHEV, J.D. BURTON, SITARAM JASWAL, EVGENY TSYMBAL, University of Nebraska - Lincoln — Correlations between magnetocrystalline anisotropy energy (MAE), ferroelectric (FE) polarization, and orbital magnetic moment are studied for ferroelectric/ferromagnetic heterostructures consisting of barium titanate (BaTiO_3) and thin-film iron (Fe). Using first-principles calculations we investigated different geometries of the BaTiO_3/Fe system, in particular with 1, 3, and 5 monolayers of Fe with either a free vacuum surface or Cu as a capping layer. We show that there is a large MAE change ($\sim 20\%$) upon switching of the polarization sign in the case of a vacuum layer, while the presence of Cu effectively removes the difference in MAE for opposite FE polarization directions in BaTiO_3 . This is explained by analyzing the correlation between MAE and orbital magnetic moments for different geometries and opposite polarization directions, as well as the film thickness. We show that the magnetoelectric coupling between MAE and FE polarization is directly linked to the degree of the magnetoelectric coupling between orbital moment and FE polarization.

4:30PM T9.00007 Electron-mediated ferromagnetic behavior in CoO/Al:ZnO multilayers¹

FRANCES HELLMAN, HYEON-JUN LEE, CATHERINE BORDEL, Physics Department, University of California, Berkeley, JULIE KAREL, Department of Materials Science and Engineering, University of California, Berkeley, DAVID W. COOKE, Physics Department, University of California, Berkeley, FRANCES HELLMAN'S GROUP TEAM — (111)-oriented epitaxial CoO/Al-doped ZnO (AZO) multilayers show a ferromagnetic behavior up to room temperature. Their magnetization exhibits an oscillatory behavior as a function of (i) the number of Co layers in the insulating antiferromagnetic CoO, and (ii) the thickness of the AZO layers. The ferromagnetism vanishes if AZO is replaced by intrinsic ZnO. This behavior can be explained by the existence of an RKKY-coupling, mediated by the free electrons of the non-magnetic AZO layers, between the uncompensated (111) ferromagnetic planes of insulating CoO when there is an odd number of planes in the layer. The oscillation period of the spontaneous magnetization as a function of the AZO layer thickness matches the Fermi wavevector calculated from the carrier concentration that was deduced from Hall effect measurements. The spin-polarization of the carriers in the AZO layer is confirmed via anomalous Hall effect.

4:42PM T9.00008 Towards Room Temperature Spin Filtering in Oxide Tunnel Junctions¹

JODI IWATA-HARMS, FRANKLIN WONG, University of California, Berkeley, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, YURI SUZUKI, University of California, Berkeley — Spin filtering, in which the magnetic tunnel barrier preferentially filters spin-up and spin-down electrons from a nonmagnetic electrode, has been demonstrated in junction heterostructures. By incorporating two spin filtering barriers, double spin filter magnetic tunnel junctions (DSF-MTJs) were predicted to yield magnetoresistance (MR) values orders of magnitude larger than that of conventional magnetic tunnel junctions. Recently, DSF-MTJs have exhibited spin filtering with magnetic electrodes at room temperature and at low temperature with nonmagnetic electrodes in EuS-based devices [1,2]. We have fabricated DSF-MTJs with nonmagnetic SrRuO₃ electrodes and room temperature ferrimagnets, NiFe₂O₄ and CoFe₂O₄, for spin filters in pursuit of room temperature functionality. Atomic force microscopy shows smooth films quantified by roughness values between 0.1–0.5nm. X-ray magnetic circular dichroism reveals ferromagnetic Ni²⁺ and Co²⁺, and element-specific hysteresis loops indicate the independent switching of the two spin filters. Transport data reveals junction MR and non-linear I-V characteristics consistent with tunneling.

4:54PM T9.00009 Magnetic Behavior of Complex Oxide Magnetic Tunnel Junctions¹

SUZANNE G.E. TE VELTHUIS, YAOHUA LIU, J.W. FREELAND, Argonne National Laboratory, USA, M. ZHERNENKOV, M.R. FITZSIMMONS, Los Alamos National Laboratory, USA, C. VISANI, M. BIBES, A. BARTHÉLÉMY, Unité mixte de Physique CNRS/Thales, France, F. CUELLAR, Z. SEFRIQUI, C. LEON, J. SANTAMARIA, Universidad Complutense de Madrid, Spain — Half metallic manganese oxides have the potential of producing a large tunneling magnetoresistance (TMR) due to their high spin-polarization. To explore their applicability we investigated magnetic tunnel junctions (MTJs) with ferromagnetic La_{0.7}Ca_{0.3}MnO₃ (LCMO) electrodes and an insulating PrBa₂Cu₃O₇ (PBCO) barrier. In these MTJs, with temperature, the TMR peaks rather than increasing with decreasing T [1]. Our Polarized Neutron Reflectivity studies reveal differences in the magnetization, reversal behavior, and anisotropy, between the bottom and top LCMO layers. As was observed in the YBa₂Cu₃O₇ (YBCO)/LCMO system [2,3], with X-Ray Magnetic Circular Dichroism we have found a non-zero net moment on the Cu of PBCO at low temperature, originating at the interface. Unlike for YBCO, the Cu moment does not persist up to T_C of LCMO. These combined results provide a possible origin of the anomalous TMR behavior.

5:06PM T9.00010 Ferroelectric control of orbital occupancy in manganites¹

HANGHUI CHEN, Department of Physics, Yale University, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — Recent successful fabrication of epitaxial and coherent ferroelectric/manganite interfaces makes it possible to dynamically control charge and spin in manganites [1]. We demonstrate with *ab initio* calculations that in this system, *d*-orbital occupancies of the interfacial Mn atom can also be modulated by flipping the ferroelectric polarization (i.e. flippable orbital polarization). The underlying mechanism is the structural distortions of the oxygen octahedron and the Mn atom inside induced by the ferroelectric polarization. The in-plane orbital *d*_{x²-y²} is stabilized by rumpling in MnO₂ layers, while the Jahn-Teller distortion (*c/a* > 1) favors the out-of-plane orbital *d*_{3z²-r²}. This ferroelectric control of orbital occupancy serves as a new approach separate from strain for engineering orbital orderings in transition metal oxides.

5:18PM T9.00011 Giant tunneling electroresistance (up to ~10,000%) in

La_{0.7}Sr_{0.3}MnO₃/BaTiO₃/La_{0.5}Ca_{0.5}MnO₃/La_{0.7}Sr_{0.3}MnO₃ ferroelectric tunnel junctions, YUEWEI YIN, QI LI, Department of Physics, Pennsylvania State University, University Park, PA 16802, USA, J.D. BURTON, E.Y. TSYMBAL, Department of Physics and Astronomy, Nebraska Center for Materials and Nanoscience, University of Nebraska, Lincoln, NE 68588, USA, X.G. LI, Hefei National Laboratory for Physical Sciences at Microscale, Department of Physics, University of Science and Technology of China, Hefei 230026, PRC — Tunnel junction with a Ferroelectric (FE) barrier (FTJ) presents an opportunity for nanoelectronics because of the bi-stable electric field control of the tunneling resistance. FTJs of La_{0.7}Sr_{0.3}MnO₃/BaTiO₃/La_{0.5}Ca_{0.5}MnO₃/La_{0.7}Sr_{0.3}MnO₃ have been fabricated with pulsed-laser deposition. The special feature in the FTJ design is to insert an ultrathin (0.4 - 1.2 nm) La_{0.5}Ca_{0.5}MnO₃ film between La_{0.7}Sr_{0.3}MnO₃ Ferromagnetic (FM) electrode and BaTiO₃ FE barrier. A giant and reproducible tunneling electroresistance effect (~10,000%) was obtained with the reversal of FE polarization, about two orders of magnitude larger than the similar sized FTJ without the inserted La_{0.5}Ca_{0.5}MnO₃ layer. This result is consistent with the theoretical prediction [PRL 106, 157203 (2011)] that at a BaTiO₃/La_{0.5}Ca_{0.5}MnO₃ interface, an anti-FM insulating - FM metallic phase transition can occur in La_{0.5}Ca_{0.5}MnO₃ when the polarization of the BaTiO₃ is reversed due to the interfacial charge doping effect.

Session T10 DMP: Invited Session: Earth-Abundant Materials for Critical Technologies 210A

2:30PM T10.00001 An Overview of Rare Earth Science and Technology¹ , KARL GSCHNEIDNER, JR., Iowa

State University — Currently rare earth science and technology is robust: this includes all the major branches of science – biochemistry, chemistry, materials and physics. There are, however, currently some anomalies and distortions especially in the technology and applications sector of the rare earth field, which is caused by the dominance of China on the sales of rare earths and rare earth containing products. For the past 5 to 10 years ~95% of rare earths utilized in commerce came from China. Although Chinese actions have led to sudden and large price spikes and export embargoes, the rare earths are still available but at a higher cost. The start up of production in 2011 at mines in the USA and Australia will alleviate this situation in about two years. Basic and applied research on the condensed matter physics/materials science has hardly been impacted by these events, but new research opportunities are opening up especially with regard to the USA's military and energy security. Magnets seems to be the hottest topic, but research on battery materials, phosphors and catalysts are also (or should be) strongly considered.

¹This work is supported by the U.S. Department of Energy - Basic Energy Sciences under contract No. DE-AC02-07CH11358.

3:06PM T10.00002 Replacing critical rare earth materials in high energy density magnets¹ ,

R. WILLIAM MCCALLUM, Ames Laboratory USDOE / Iowa State University — High energy density permanent magnets are crucial to the design of internal permanent magnet motors (IPM) for hybride and electric vehicles and direct drive wind generators. Current motor designs use rare earth permanent magnets which easily meet the performance goals, however, the rising concerns over cost and foreign control of the current supply of rare earth resources has motivated a search for non-rare earth based permanent magnets alloys with performance metrics which allow the design of permanent magnet motors and generators without rare earth magnets. This talk will discuss the state of non-rare-earth permanent magnets and efforts to both improve the current materials and find new materials. These efforts combine first principles calculations and meso-scale magnetic modeling with advance characterization and synthesis techniques in order to advance the state of the art in non rare earth permanent magnets. The use of genetic algorithms in first principle structural calculations, combinatorial synthesis in the experimental search for materials, atom probe microscopy to characterize grain boundaries on the atomic level, and other state of the art techniques will be discussed. In addition the possibility of replacing critical rare earth elements with the most abundant rare earth Ce will be discussed.

¹Work at The Ames Laboratory was supported by the U.S. DOE under Contract No. DE-AC02-07CH11358.

3:42PM T10.00003 Solar to Fuel Conversion with Earth Abundant Materials , DANIEL G. NOCERA,

Massachusetts Institute of Technology — Studies in the Nocera group have led to the creation of a new earth-abundant catalyst that captures many of the functional elements of photosynthesis and in doing so provides a highly manufacturable and inexpensive method to effect a carbon-neutral and sustainable method for solar storage - solar fuels from water-splitting. This discovery enables an inexpensive 24/7 solar energy system for the individual, a capability that is attractive in the underdeveloped as well as the developed world.

4:18PM T10.00004 Organic-inorganic hybrid materials for energy efficiency , SETH COE-SULLIVAN, QD

Vision, Inc. — Quantum dot (QD) semiconductor nanocrystals are unique hybrid materials that have been considered in a broad range of energy production and energy efficiency applications including LEDs, displays, lighting and solar cells. In their photoluminescent mode of operation, QDs are currently in lighting products, and have the promise to be in liquid crystal display products in the near future, in both cases offering energy efficiency gains in the range of 25-40%. In electroluminescent mode, quantum dot light emitting devices (QLEDs) are an emerging class of thin-film hybrid organic-inorganic structures that can potentially achieve best-in-class performance amongst large-area emissive light sources. Indeed, efficiencies which double that of the most efficient OLEDs have been suggested. The hybrid nature of these materials offers the key design parameters that have enabled QD technology to reach market in lighting products, and promises to soon revolutionize the display industry.

4:54PM T10.00005 Photovoltaic devices using inexpensive, abundant inorganic materials: experiences with copper zinc tin sulfide (CZTS) , SUPRATIK GUHA, IBM Thomas J. Watson Research Center —

For photovoltaics to be able to contribute a significant percentage of global electricity, we ideally desire a cheap, efficient, safe, and abundant solar cell that can be treated more as a construction material than as a delicate semiconductor. We are not quite there yet, though thin film polycrystalline solar cells on cheap substrates represent a potential way to accomplish this objective. I will describe some of the requirements for a solar cell with this application objective, describe some of the challenges when we desire to transform a “polycrystalline,” “mineral-like” absorber into an efficient p-n junction solar cell, and in this context will describe our results with the kesterite compound copper zinc tin sulfide (CZTS).

Wednesday, February 29, 2012 2:30PM - 5:18PM –

Session T11 DMP: Focus Session: Graphene Structure, Stacking, Interactions: Twisted Layers

210B

2:30PM T11.00001 Continuum Model of the twisted graphene bilayer¹ , JOÃO LOPES DOS SANTOS, CFP

and DFA, Faculdade de Ciências, Universidade do Porto — The electronic structure of the twisted bilayer was first considered [1] in the context of a continuum description of the two layers, coupled by a spatially modulated hopping. The model's predictions were subsequently confirmed by experiments [2,3], including a scanning tunneling spectroscopy finding of two low energy Van-Hove peaks in the density of states [4], and by band structure calculations [5,6]. We discuss the extension of the model in several directions: the two families of commensurate structures discovered by Mele [7], will be characterized by elementary geometrical arguments; it will be shown that it is possible to calculate analytically *all* Fourier components of the hopping amplitudes for any kind of commensurate structure with large period; the calculations will be extended beyond the perturbative regime in the interlayer coupling to address the electronic structure and local density of states in the very small angle limit.

3:06PM T11.00002 Moire Bloch Bands in Twisted Bilayer Graphene, ALLAN MACDONALD, University of Texas at Austin — A moiré superlattice pattern is formed when two copies of a periodic lattice are overlaid with a relative twist. I will address the electronic structure of a twisted two-layer graphene system by generalizing the Dirac equation continuum models that are used to describe single-layer graphene and untwisted bilayers. In the Dirac model electrons in graphene have a pseudospin degree-of-freedom corresponding to the honeycomb sublattice dependence of wavefunction amplitudes. The continuum model of twisted bilayers can be derived systematically [1] by assuming that interlayer tunneling amplitudes are non-local with a range that is large compared to the honeycomb lattice constant, and leads to an appealing picture in which the tunneling operator has a position-dependent pseudospin dependence that simply reflects the local registry between the two honeycombs. The continuum model twisted bilayer Hamiltonian is therefore periodic, with the periodicity of the moiré pattern, and insensitive to the incommensurability of the microscopic Hamiltonian. I will discuss the properties of the Bloch bands of this periodic Hamiltonian, which become highly non-trivial at small twist angles. In particular the Dirac velocity crosses zero several times as the twist angle is reduced and vanishes at a discrete set of magic angles. I will also briefly discuss the Hofstadter butterfly spectral patterns [2] created by incommensurability between the moiré pattern and magnetic lengths when a twisted bilayer is placed in an external magnetic field, and the electronic structure [3] of a single graphene layer that is twisted with respect to a boron nitride substrate.

3:42PM T11.00003 Anomalies in the magneto-optical conductivity of twisted multilayer epitaxial graphene, ALEXEY B. KUZMENKO, IRIS CRASSEE, JULIEN LEVALLOIS, DIRK VAN DER MAREL, University of Geneva, Switzerland, ANDREW L. WALTER, Advanced Light Source, USA., THOMAS SEYLLER, University of Erlangen-Nuremberg, Germany — The nature of the electronic coupling between carbon layers in twisted multilayer graphene is an intriguing and hot-debated issue. We measured the Faraday rotation and optical absorption spectra of twisted graphene multilayers grown on the carbon face of SiC in the far-infrared range in magnetic fields up to 7 Tesla [1,2]. Multiple spectral components are identified, which include a quasi-classical cyclotron resonance, originating from the highly doped graphene layer closest to SiC, transitions between low-index Landau levels (LLs), which stem from quasineutral outer layers and a broad optical absorption background, which provenance is less obvious. Electron- and hole-type LL transitions are optically distinguished and shown to coexist. The variation of the Fermi velocity is about 10 percent across the layers. Our central observation is an anomalously small optical spectral weight of the individual LL transitions, which is likely caused by the unusual electronic coupling between randomly stacked graphene layers.

[2] I. Crassee *et al.* Phys Rev B **84**, 035103 (2011).

3:54PM T11.00004 Quantum Hall Effect, Screening and Layer-Polarized Insulating States in Twisted Bilayer Graphene¹, JAVIER D. SANCHEZ-YAMAGISHI, Department of Physics, MIT, THITI TAYCHATANAPAT, Department of Physics, Harvard, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Tsukuba, Japan, AMIR YACOBY, Department of Physics, Harvard, PABLO JARILLO-HERRERO, Department of Physics, MIT — We present a study of electronic transport in dual-gated twisted bilayer graphene. Despite the sub-nanometer proximity between the layers, we identify independent contributions to the magnetoresistance from the graphene Landau level spectrum of each layer. We demonstrate that the filling factor of each layer can be independently controlled via the dual gates, which we use to induce Landau level crossings between the layers. By analyzing the gate dependence of the Landau level crossings, we characterize the finite inter-layer screening and extract the capacitance between the atomically-spaced layers. At zero filling factor, we observe magnetic and displacement field dependent insulating states, which indicate the presence of counter-propagating edge states with inter-layer coupling.

¹Research supported by the US Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award de-sc0001819

4:06PM T11.00005 Formation of superlattice structures by interlayer bonding in twisted bilayer graphene, ANDRE MUNIZ, Universidade Federal do Rio Grande do Sul, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We present a computational analysis of carbon nanostructure formation from twisted bilayer graphene, upon creation of interlayer covalent C-C bonds. The analysis is based on a combination of first-principles density functional theory calculations and classical molecular-dynamics simulations. We demonstrate that the resulting configurations constitute a novel class of stable structures and that their features are determined by the relative angle of rotation between the two graphene planes of the bilayer. For small angles of rotation (near 0 degrees), interlayer covalent bonding generates superlattices of diamond-like nanocrystals embedded within the graphene layers; for rotation angles near 30 degrees, superlattices of caged fullerene-like configurations are generated. We calculate the electronic band structure of these superlattices and show that their band gap can be controlled through selective hydrogenation and creation of interlayer bonds. We also show that the linear dispersion around the K point in the first Brillouin zone (Dirac cones), characteristic of single-layer and non-bonded twisted bilayer graphene, is preserved for some of these structures in spite of the introduction of sp³ bonds due to hydrogenation and interlayer C-C bonding.

4:18PM T11.00006 Phonon mediated conductance in misoriented graphene bilayers, VASILIOS PEREBEINOS, JERRY TERSOFF, PHAEDON AVOURIS, IBM - Watson — Electrical transport in a misoriented graphene bilayer is facilitated by umklapp processes whose strength is known to decrease rapidly with the number of atoms in the commensurate cell. As the misorientation angle is reduced, the number of atoms increases, and the umklapp conductance in an ideal (infinitely large and defect free) bilayer becomes negligible. We show that at room temperature coupling to the out-of-plane phonon vibrations leads in a conductance several orders of magnitude larger than that produced by pure electronic umklapp. The most relevant phonons originate from the flexural modes of the monolayer, vibrating out-of-phase in the bilayer, with energies around 80 cm⁻¹ near the Γ -point. These phonon modes disperse nearly quadratically away from the center of the Brillouin zone. As the misorientation angle is reduced, the relevant phonon wavevector connecting the two Fermi surfaces in monolayers is reduced as well, which results in larger phonon mediated conductance. This is the opposite behavior to that expected from the umklapp conductance. We will present calculations of phonon mediated conductance as a function of misorientation angle, doping, temperature, and applied bias, for a tight-binding electron-phonon Hamiltonian.

4:30PM T11.00007 Probing interlayer interactions in twisted bilayer graphene with Raman spectroscopy, ROBIN HAVENER, Applied and Engineering Physics, Cornell University, LOLA BROWN, Chemistry and Chemical Biology, Cornell University, HOULONG ZHUANG, Materials Science and Engineering, Cornell University, MICHAL WOJCIK, Chemistry and Chemical Biology, Cornell University, CARLOS RUIZ-VARGAS, Applied and Engineering Physics, Cornell University, RICHARD G. HENNIG, Materials Science and Engineering, Cornell University, JIWOONG PARK, Chemistry and Chemical Biology, Cornell University — Chemical vapor deposition (CVD) growth or artificial layer-by-layer assembly of graphene typically produces multi-layer regions in which the layers are twisted with respect to each other, but the electronic and optical properties of this new material are still under investigation. In particular, little is known about how the twist angle affects the Raman signature of this material. We use a combination of dark-field transmission electron microscopy (DF-TEM) and widefield Raman imaging (WRI) to study the Raman signature of bilayer CVD graphene regions with known twist angles. We find that the intensities of the G and 2D peaks vary predictably with twist angle. In particular, we observe a strong G band enhancement at a specific twist angle that depends on our excitation energy. To explain this behavior, we model the electronic band structure of twisted bilayer graphene; the interaction between layers creates new saddle point van Hove singularities, and these energy states can enable a fully resonant G band pathway for a specific angle and excitation energy. This G band resonance feature is a very sensitive probe of twist angle and interlayer interactions.

4:42PM T11.00008 Strong Rotational Angle Dependence of Raman Spectroscopy in Rotated Double-Layer Graphene, KWANPYO KIM, SINISA COH, LIANG Z. TAN, WILLIAM REGAN, JONG MIN YUK, ERIC CHATTERJEE, M. F. CROMMIE, MARVIN L. COHEN, STEVEN G. LOUIE, A. ZETTL, Department of Physics, UC Berkeley — We perform a complementary Raman spectroscopy and transmission electron microscopy (TEM) study, as well as electronic-structure and Raman calculations, on suspended rotated double-layer graphene. Graphene Raman spectra show a strong dependence on the rotational angles between two stacked layers. For low-angle mis-orientations (~ 10 degrees), double-layer graphene exhibits Raman signature closer to AB-stacked bilayer graphene. Double-layers with high rotational angles ($> \sim 15$ degrees), on the other hand, display Raman spectra similar to monolayer graphene. Rotational angle dependent modifications of the electronic band structure in double-layer graphene can explain this trend and a G peak enhancement at certain middle angles. The computed electronic band structures and key features of the graphene Raman peaks including the blue shift, width and intensity of the 2D peaks agree well with experimental data.

4:54PM T11.00009 Effect of stacking on the transport properties of few-layer graphene: NEGF-DFT investigation, MATHEUS LIMA, JOSÉ EDUARDO PADILHA, RENATO PONTES, ANTÔNIO J. R. DA SILVA, ADALBERTO FAZZIO, University of São Paulo (IFUSP) — We study the effect of the stacking order on the electronic transport properties of few-layer graphene (FLG) by performing ab initio calculations based on the formalism that combines non-equilibrium green's functions and density functional theory. The stacking of the layers - Bernal (ABA), Rhombohedral (ABC) or even a combination between them - have to be considered as an extra degree of freedom and consequently the FLG properties are highly sensitive to the stacking configuration. In particular, the band structures and the transport properties of FLG present a behavior markedly distinct from that for single layer. We consider FLG from trilayer to dodecalayer in both stacks. We show that for FLG, in the Rhombohedral stacking, a simple counting of bands cannot be used to predict the amount of conducting channels. We also show that for FLG, in the Rhombohedral stacking, the outermost layers dominate the contribution to the transmittance whereas for the Bernal stacking the innermost layers also present a significant contribution to the transmittance. Moreover, we investigate the effect of bias voltage and the temperature in the transport properties of FLG. We acknowledge the INCT/CNPq, CAPES and FAPESP for the financial support.

5:06PM T11.00010 First principles study of trilayers of graphene-BN-graphene¹, XIAOLIANG ZHONG, RODRIGO AMORIM, RAVINDRA PANDEY, Michigan Technological University, SHASHI KARNA, US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: RDRL-WM — The stability, electronic structure and electronic transport properties of graphene-BN-graphene (C-BN-C) trilayers are studied in the framework of density functional theory. Different stacking formats, i.e., AAA, ABA and ABC stackings are considered. The ABA stacking is found to be most energetically favorable, followed by ABC and AAA stackings. The interlayer spacing of trilayers are close to those of corresponding C-BN bilayers, while the intralayer bond length can be regarded as the weighted mean of constituent layers. All considered configurations are found to be metallic, independent of stacking formats. When an external electric field is applied perpendicularly, electronic band structures undergo stacking-dependent variations. While both AAA and ABA stackings show good tunability of energy gap, ABC stacking shows less flexibility of gap tuning. We will also present the results of the electronic transport properties which are modeled by sandwiching trilayers between gold contact electrodes.

¹The work at Michigan Technological University was performed under support by the Army Research Laboratory through Contract No. W911NF-09-2-0026-133417.

Wednesday, February 29, 2012 2:30PM - 5:18PM —
Session T12 DMP: Focus Session: Graphene: Growth, Mechanical Exfoliation, and Properties - CVD on Metals 210C

2:30PM T12.00001 Characterization of Few Layer Graphene films Grown on Cu, Cu-Ni and SiC Substrates¹, P. TYAGI, J.D. MCNEILAN, J. ABEL, F.J. NELSON, Z.R. ROBINSON, R.L. MOORE, A.C. DIEBOLD, V.P. LABELLA, C.A. VENTRICE, JR., Univ. at Albany, A. SANDIN, D.B. DOUGHERTY, J.E. ROWE, North Carolina State Univ., C. DIMITRAKOPOULOS, A. GRILL, C.Y. SUNG, IBM T.J. Watson, S. CHEN, A. MUNSON, C.W. MAGNUSON, R.S. RUOFF, Univ. of Texas — The electronic structure of graphene depends on the number of graphene layers and the stacking sequence between the layers. Therefore, it is important to have a non-destructive technique for analyzing the overlayer coverage of graphene directly on the growth substrate. We have developed a technique using angle-resolved XPS to determine the average graphene thickness directly on metal foil substrates and SiC substrates. Since monolayer graphene films can be grown on Cu substrates, these samples are used as a standard reference for a monolayer of graphene. HOPG is used as a standard reference for bulk graphite. The electron mean free path of the C-1s photoelectron can be determined by analyzing the areas under the C-1s peaks of monolayer graphene/Cu and bulk graphite. With the electron mean free path, the graphene coverage of a film of arbitrary thickness can be determined by analyzing the area under the C-1s of that sample. Analysis of graphene coverages for graphene films grown on Cu-Ni substrates and of the thickness of both the graphene overlayer and intermediate buffer layer on SiC will be presented.

¹Support from the NSF (1006350/1006411) and ONR is appreciated.

2:42PM T12.00002 Investigation of large-area graphene synthesized on palladium surface, XIAOHONG AN, FANGZE LIU, Department of Physics, Northeastern University, YUNGJOON JUNG, Department of Mechanical and Industrial Engineering, Northeastern University, SWASTIK KAR, Department of Physics, Northeastern University, DEPARTMENT OF PHYSICS COLLABORATION, DEPARTMENT OF MECHANICAL AND INDUSTRIAL ENGINEERING COLLABORATION — We present a detailed study of large-area growth of graphene on palladium substrates. By studying the growth at different stages through appropriate variations of the temperature and time intervals of growth, and by investigating the growth at different regions of the metal substrate we have been able to observe a number of important properties of graphene growth on Pd surfaces. We have explored the nature of the as-synthesized graphene through a combination of electron microscopy and Raman spectroscopic analysis. Raman analysis of the graphene enables us to identify different kinds of as-synthesized graphene, including monolayer, turbostratic multi-layer, and mixed Bernal-turbostratic graphene layers. We further demonstrate a systematic study of the evolution of these different types of graphene as a function of temperature and growth-time.

2:54PM T12.00003 Crystallographic effects of copper substrate on graphene growth and fluorination, JOSHUA WOOD, SCOTT SCHMUCKER, GREGORY DODGE, THADDEUS KRAWCZYK, AUSTIN LYONS, ERIC POP, JOSEPH LYDING, University of Illinois at Urbana-Champaign — Graphene grown by chemical vapor deposition (CVD) on Cu is appealing due to supposed large-area monolayer growth and the low cost of the Cu foil substrate. However, this Cu substrate is inherently polycrystalline, with low and high index facets, annealing twins, and rough sites. We characterize CVD graphene growth on the Cu surfaces by combining Raman spectroscopy, electron-backscatter diffraction (EBSD), and scanning electron microscopy (SEM). We find that graphene growth on Cu(100) is multilayered and of low-quality, while growth on Cu(111) is monolayer and of high-quality. High index Cu facets containing a high percentage of (111) terraces are more monolayer-like than Cu(100). Graphene has a higher growth rate on (111) surfaces, growing the fastest on Cu(111). At temperatures below 900 °C, compact islands of graphene form from lowered growth rate. To open a bandgap in graphene, quantum confinement or covalent chemistry must be used. We do the latter by exposing our graphene films to XeF₂ gas, terminating in an insulating C₄F stoichiometry and covalent C-F bonds. Rougher facets fluorinate first, which allows possible bandgap engineering by the Cu crystallography. Additionally, film defects assist in fluorination effectiveness. We also show preliminary results on Cu crystallography effects for CVD of hexagonal boron nitride (h-BN).

3:06PM T12.00004 Barrier-Guided Growth of Micro- and Nano-Structured Graphene, NATHANIEL SAFRON, MYUNGWOONG KIM, PADMA GOPALAN, MICHAEL ARNOLD, University of Wisconsin: Madison — The patterning of graphene is necessary for tuning its physical and electronic structure and for device-integration. Traditionally, patterning has been achieved via *top-down* chemical or physical etching, which induces defects and disorder that degrades performance. In this work, we overcome these challenges through a fundamentally new *bottom-up* growth method for the rational synthesis of patterned graphene called Barrier-Guided Chemical Vapor Deposition (BG-CVD). We deposit patterned barriers on the Cu surface, using scalable lithography methods, which guide the growth of graphene around them into any desired shape. The barriers locally passivate the surface, (i) preventing the decomposition of the methane, and (ii) blocking the growth of graphene on the barrier. By designing appropriate barrier layers, we have grown arbitrary patterns, nanoribbons, and nanoporated graphene with features down to 25 nm with high mobility ($215 \text{ cm}^2/\text{Vs}$). These materials are highly crystalline with domain size $>4 \mu\text{m}$ and have 2-10x less edge defects than comparable top-down etched materials. The pattern reproducibility is $<1 \text{ nm}$ and thus, ultimately, should enable the bottom-up synthesis of sub-5 nm features. These results indicate BG-CVD as a superior production route to patterned graphene.

3:18PM T12.00005 Synthesis of Large-grain, Single-crystalline Graphene by a Novel Chemical Vapor Deposition Method and Electrical properties, YI ZHANG, LUYAO ZHANG, PYOJAE KIM, MINYUAN GE, CHONGWU ZHOU, University of Southern California — Graphene, a two dimensional, honey comb arrangement of carbon atoms has drawn significant attention with its interesting physical and electronic properties. Tremendous efforts have been made to synthesize large-scale, high quality, single-layer graphene (SLG). Based on previous studies, CVD graphene with large grain size (less grain boundaries) and low defect density would show an enhancement of device mobility. Here we report a novel CVD method to synthesize graphene with grain size up to several hundreds of micrometers on copper foil. Raman surface map of individual graphene grain indicated that the large-grain graphene was single-layer and with very low defect density. Selected Area Electron Diffraction (SAED) also confirmed that the each individual graphene island was a single grain. Morphology study was also performed to investigate the relation between the shape of graphene and growth parameters. Furthermore, the large-grain graphene was transferred to SiO_2/Si for the field effect study, and the device mobility derived from the large-grain graphene was $\sim 5,200 \text{ cm}^2/\text{V.s}$. The achieved high device mobility indicates that the large-grain single-crystalline graphene is of great potential for graphene-based nanoelectronics.

3:30PM T12.00006 Mesoscale STM Study of Thermally Annealed Copper Foils¹, OLESYA SARAJLIC, RAMESH MANI, Georgia State University — The growth of high quality graphene has become a topic of significance. There have been utilized several methods of material growth including the epitaxial growth on SiC, method of exfoliation of graphite, and chemical vapor deposition (CVD). The CVD approach typically utilizes foils of copper or nickel that are exposed to organic compounds at a high temperature. The purpose of the study is to investigate the role of the metal surface morphology during the growth process, relative grain size before and after thermal treatment, and relative flatness of the substrate after annealing. We investigated the effects of thermal annealing of polycrystalline Cu foil at the mesoscale using an ultrahigh vacuum (UHV) scanning tunneling microscope (STM). Prolonged low-temperature and rapid high-temperature annealing of the samples is being carried out and the resulting surface morphology will be reported. The STM observations reveal that the film quality is limited by grain boundaries.

¹ARO:W911NF-07-01-0158,DOE:DE-SC0001762

3:42PM T12.00007 Graphene Crystal Growth and Device Integration, LUIGI COLOMBO, Texas Instruments Incorporated — Graphene has unique electronic, chemical, thermal and physical properties and this is opening many opportunities for its use. However, to date the majority of the experiments have been performed on exfoliated graphene. There is a need to develop high quality, large area single crystal graphene for electronic applications. The discovery of graphene growth copper by chemical vapor deposition (CVD) has led to the growth of polycrystalline large area (square meters) films. The domain size for the baseline process is a few tens of microns in diameter but large "crystals," 0.25 square mm, have been grown. However, even though the films are not yet fully single crystals the transport properties are equivalent to those of exfoliated graphene. The ultimate usefulness of any material for electronics is the ability to integrate it with dielectrics and metals. Graphene is chemically inert and will require special processes to integrate it with dielectrics and metals without interrupting its band structure. The objective of this presentation is to review and present new data on large area graphene crystal growth and integration of dielectrics and metals. Surface analysis of graphene with dielectrics and metals under various processing conditions will also be presented.

4:18PM T12.00008 In Situ Characterization of Alloy Catalysts for Low-Temperature Graphene Growth, ROBERT WEATHERUP, BERNHARD BAYER, BRUNO DLUBAK, PIRAN KIDAMBI, Dept. Engineering, University of Cambridge, RAOUL BLUME, Helmholtz-Zentrum Berlin, CATERINA DUCATI, Dept. Materials Science and Metallurgy, University of Cambridge, CARSTEN BAEHTZ, Helmholtz-Zentrum Dresden-Rossendorf, ROBERT SCHLOEGL, Fritz Haber Institute, STEPHAN HOFMANN, Dept. Engineering, University of Cambridge — Chemical vapor deposition (CVD) on transition metal catalysts offers a low-cost method of producing large-area graphene, but due to limited understanding of the underlying mechanism(s), growth control remains rudimentary. We use in situ X-ray photoelectron spectroscopy (XPS) and X-ray diffraction (XRD) to monitor catalytic CVD on Ni based catalysts under typical reactor conditions. We thus develop a coherent model for graphene formation and show that graphene growth occurs during isothermal hydrocarbon exposure and is not limited to precipitation upon cooling. We introduce alloy catalysts to improve graphene growth by tuning reactivity and selectivity. We show that alloying polycrystalline Ni with Au allows low temperature ($<450^\circ\text{C}$) CVD of predominantly monolayer ($>74\%$) graphene films with an average D/G peak ratio of ~ 0.24 and domain sizes in excess of $220 \mu\text{m}^2$ [1]. We suggest that Au decorates a majority of high reactivity Ni surface sites, such as step edges, and lowers the stability of surface C. Au alloying thereby drastically lowers the graphene nucleation density, allowing more uniform and controlled growth at CMOS compatible temperatures. [1] Weatherup et al. Nano Lett. 11, 4154 (2011)

4:30PM T12.00009 ACCVD growth of mono- and bi-layer graphene and mechanism study, XIAO CHEN, PEI ZHAO, BO HOU, ERIK EINARSSON, SHOHEI CHIASHI, SHIGEO MARUYAMA, Maruyama-Shiomi Lab, Department of Mechanical Engineering, The University of Tokyo — CVD on metal substrates has been proved to be effective in the synthesis of graphene. But before utilization in graphene electronics, the quality of the consequential graphene needs to be improved, and a reliable method to grow large-scale, high-quality bi-layer graphene is required. Besides, the mechanism of growth is not fully understood. Here we report utilizing Alcohol catalytic CVD (ACCVD) to produce mono- and bi-layer graphene. By applying alcohol as carbon source, we carefully studied how each parameter affects the growth process, and the defects and grain size of graphene. By changing growth conditions we could efficiently control the layer number (1 or 2). Afterwards, we conducted and compared the transfer procedures utilizing three commonly used mediators—PVA, PDMS and PMMA. We also employed ^{12}C , ^{13}C , and $2\text{-}^{13}\text{C}$ ethanol to synthesize graphene, and with the spectroscopy characterization results we are able to explain the growth mechanism on Cu and Ni substrates to a certain extent.

4:42PM T12.00010 Synthesis and sensing application of large scale bilayer graphene, SUNG JU HONG, JUNG HOON YOO, SEUNG JAE BAEK, YUNG WOO PARK, Seoul National University — We have synthesized large scale bilayer graphene by using Chemical Vapor Deposition (CVD) in atmospheric pressure. Bilayer graphene was grown by using CH_4 , H_2 and Ar gases. The growth temperature was 1050°C . Conventional FET measurement shows ambipolar transfer characteristics. Results of Raman spectroscopy, Atomic Force microscope (AFM) and Transmission Electron Microscope (TEM) indicate the film is bilayer graphene. Especially, adlayer structure which interrupt uniformity was reduced in low methane flow condition. Furthermore, large size CVD bilayer graphene film can be investigated to apply sensor devices. By using conventional photolithography process, we have fabricated device array structure and studied sensing behavior.

4:54PM T12.00011 ABSTRACT WITHDRAWN —

5:06PM T12.00012 CVD growth of graphene at low temperature, CHANGGAN ZENG, Department of Physics, University of Science and Technology of China — Graphene has attracted a lot of research interest owing to its exotic properties and a wide spectrum of potential applications. Chemical vapor deposition (CVD) from gaseous hydrocarbon sources has shown great promises for large-scale graphene growth. However, high growth temperature, typically 1000°C, is required for such growth. In this talk, I will show a revised CVD route to grow graphene on Cu foils at low temperature, adopting solid and liquid hydrocarbon feedstocks. For solid PMMA and polystyrene precursors, centimeter-scale monolayer graphene films are synthesized at a growth temperature down to 400°C. When benzene is used as the hydrocarbon source, monolayer graphene flakes with excellent quality are achieved at a growth temperature as low as 300°C. I will also talk about our recent progress on low-temperature graphene growth using paraterphenyl as precursor. The successful low-temperature growth can be qualitatively understood from the first principles calculations. Our work might pave a way to economical and convenient growth route of graphene, as well as better control of the growth pattern of graphene at low temperature.

Wednesday, February 29, 2012 2:30PM - 5:06PM —

Session T13 DMP GMAG: Focus Session: Low-Dimensional and Molecular Magnetism - Molecular Ferromagnetism and 2D Magnetism 211

2:30PM T13.00001 Magnetic phase diagram of quasi-2D quantum Heisenberg antiferromagnets with XY anisotropy, FAN XIAO, CHRISTOPHER LANDEE, Department of Physics, Clark University, Worcester MA 01610, MARK TURNBULL, Carlson School of Chemistry and Biochemistry, Clark University, Worcester, MA 01610, NATHANAEL FORTUNE, Department of Physics, Smith College, Northampton MA 01063, SCOTT HANNAHS, National High Magnetic Field Lab, Tallahassee, FL 32310 — The magnetic phase diagram of a quasi-2D quantum Heisenberg antiferromagnetic compound $\text{Cu}(\text{pz})_2(\text{ClO}_4)_2$ [1] has been determined by experimental measurements; TN shows a strong field dependence. The data reveal the presence of a small (0.5%) amount of XY anisotropy. QMC simulations have been performed to examine the role of the anisotropy and the interlayer exchange (') upon the phase diagram [2,3]. Comparison of the QMC results with the experimental phase diagram will be presented.

2:42PM T13.00002 Magnetic excitations of the $S=1/2$ square lattice antiferromagnet $\text{CuF}_2(\text{H}_2\text{O})_2(\text{pyz})$ ($\text{pyz}=\text{pyrazine}$), CUIHUA WANG, MARK D. LUMSDEN, RANDY S. FISHMAN, GEORG EHLERS, TAO HONG, Oak Ridge National Laboratory, JOHN A. SCHLUETER, CORTNEY DUNMARS, Argonne National Laboratory, JAMIE L. MANSON, Eastern Washington University, ANDREW D. CHRISTIANSON, Oak Ridge National Laboratory — We have studied the magnetic structure and excitations of the two dimensional $S=1/2$ square lattice antiferromagnet deuterated $\text{CuF}_2(\text{H}_2\text{O})_2(\text{pyz})$. The neutron diffraction measurements show that the antiferromagnetic structure is collinearly arranged with the estimated magnetic moment of $0.60 \pm 0.07 \mu_B/\text{Cu}$. This value is much smaller than the single ion magnetic moment, reflecting the presence of strong quantum fluctuations. The spin wave dispersion from magnetic zone center to the zone boundary point ($\pi/2 \pi/2$) can be roughly described by a 2d Heisenberg model with a magnetic exchange constant $J_{2d} = 1.099 \pm 0.002 \text{ meV}$ and a tiny contribution from an inter-plane interaction (J_{perp} is about 1% of J_{2d}). This is close to the first principles DFT calculations while about two times larger than the value extracted by fitting of the magnetic susceptibility. Compared to ($\pi/2 \pi/2$), preliminary measurements of the spin excitation at the zone boundary point ($\pi 0$) shows an obvious suppression of the excitation energy. This suppression is expected on the basis of quantum Monte Carlo and series expansion calculations for the quantum corrections of linear spin wave theory.

2:54PM T13.00003 Edge state and its stability of 2D antiferromagnetic quantum spin systems, TAKAFUMI SUZUKI, Research Center for Nano-Micro Structure Science and Engineering, University of Hyogo, MASAHIRO SATO, Department of Physics, Aoyama Gakuin University — Topological insulators (TIs) [1] have been of great interest in condensed matter physics. One of the most important points is that TIs are characterized by non-local quantities such as topological quantities of the bulk or gapless surface states [2]. The TI phase and the surface states are quite stable for any time-reversal symmetric perturbations. On the other hand, the Haldane-gap state in quantum spin systems is another class of the topological state [3], because, similarly to TIs, this gapped state has no local order and is characterized by the non-local (string) order parameter or free spins at the edges. In this study, motivated by the recent development of theories for topological phases and surface states, we consider properties of edge states in 2D quantum spin systems by applying the quantum Monte Carlo method. Particularly, we focus on the three points; (1) which spin systems can have gapless edge states, (2) the stability of the gapless edge states, and (3) the difference between the edge modes of TIs and spin systems.

3:06PM T13.00004 Absence of magnetic order in low-dimensional (RKKY) systems, FABIO PEDROCCHI, University of Basel, Department of Physics, ANTHONY LEGGETT, University of Illinois at Urbana-Champaign, Department of Physics, DANIEL LOSS, University of Basel, Department of Physics — We extend the Mermin-Wagner theorem to a system of lattice spins which are spin-coupled to itinerant and interacting charge carriers. We use the Bogoliubov inequality to rigorously prove that neither (anti-) ferromagnetic nor helical long-range order is possible in one and two dimensions at any finite temperature. Our proof applies to a wide class of models including any form of electron-electron and single-electron interactions that are independent of spin. In the presence of Rashba or Dresselhaus spin-orbit interactions (SOI) magnetic order is not excluded and intimately connected to equilibrium spin currents. However, in the special case when Rashba and Dresselhaus SOIs are tuned to be equal, magnetic order is excluded again. This opens up a new possibility to control magnetism electrically.

3:18PM T13.00005 Continuous and Discontinuous Quantum Phase Transitions in a Model Two-Dimensional Magnet, SARA HARAVIFARD, Argonne National Laboratory / The University of Chicago, ARNAB BANERJEE, The University of Chicago, JONATHAN LANG, GEORGE SRAJER, Argonne National Laboratory, DANIEL SILEVITCH, The University of Chicago, BRUCE GAULIN, McMaster University, HANNA DABKOWSKA, Brockhouse Institute for Material Research, THOMAS ROSENBAUM, The University of Chicago — The Shasty-Sutherland model consists of a set of spin 1/2 dimers on a 2-dimensional square lattice which are predicted to change from isolated, gapped excitations to a collective, ordered ground state by tuning the ratio of the intra to inter-dimer coupling. We compress the model Shastry-Sutherland material, $\text{SrCu}_2(\text{BO}_3)_2$, in a diamond anvil cell at cryogenic temperatures to continuously tune the coupling energies and induce changes in state. High-resolution x-ray measurements exploit a remarkably strong spin-lattice coupling to ascertain the physics of the magnetic transition. The singlet-triplet gap energy is suppressed continuously with increasing pressure, vanishing completely by 2 GPa. This continuous quantum phase transition is followed by a structural distortion at higher pressure corresponding to the onset of long-range order.

3:30PM T13.00006 Late-time Domain Growth in the Compressible Triangular Ising Net¹, MENG MENG, DAVID LANDAU, Center for Simulation Physics, University of Georgia — We perform large scale Monte Carlo simulations of the long-time domain growth behavior in a compressible, triangular Ising net. Unlike previous work,² our model has no bond angle interactions or lattice mismatch. The system is quenched below the critical temperature from a homogenous disordered state to an ordered phase where multiple domains coexist. We include an elastic energy part in the Hamiltonian to adjust the rigidity of the model. Theory expects the domain size $R(t)$ grows as a power law $R(t) = A + Bt^n$, where t is the time after the quench. For the rigid model we find the late-time domain size growth factor n has Lifshitz-Slosov value of $\frac{1}{3}$. For weak flexible models, we get slight reduction from $\frac{1}{3}$. For the strongly flexible model, we get a bimodal distribution of bond lengths and a dramatically reduced value of n , which has similar behavior as the mismatch model.³

3:42PM T13.00007 Atomic-scale antiferromagnets with stable Neel states, ANDREAS HEINRICH, IBM Research — A macroscopic antiferromagnet is characterized by long-range magnetic order, for example with the spin of neighboring atoms alternating their direction. Here we will discuss how far such concepts can be extended towards the atomic scale. We use low-temperature scanning tunneling microscopy with spin-polarized tips to investigate antiferromagnets consisting of a small number of Fe atoms on a thin Cu₂N substrate. As few as 8 Fe atoms show two stable magnetic states in which the spin between neighboring atoms alternates. The STM can be used to switch between these two magnetic states. When heating the spins to about 10K, spontaneous switching occurs from which the switching dynamics is deduced. Small structures show a second switching mechanism that is not dependent on temperature but strongly dependent on the length of the antiferromagnetic chain, suggesting switching by quantum tunneling of magnetization (the Neel vector).

3:54PM T13.00008 Contrasting low-dimensional magnetism in the 3D metal-organic frameworks $[\text{Cu}(\text{VF}_6)(\text{pyz})_2] \bullet 4\text{H}_2\text{O}$ and $[\text{Cu}(\text{HF}_2)(\text{pyz})_2]\text{SbF}_6$ (pyz = pyrazine)¹, JAMIE MANSON, Department of Chemistry and Biochemistry, Eastern Washington University, Cheney, WA 99004 USA, JOHN SCHLUETER, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 USA, PAUL GODDARD, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford OX1 3PU UK, JOHN SINGLETON, ROSS MCDONALD, OSCAR AYALA-VALENZUELA, MPA-NHMFL, Los Alamos National Laboratory, Los Alamos, NM 87545, TOM LANCASTER, STEPHEN BLUNDELL, Clarendon Laboratory, Department of Physics, University of Oxford, Oxford OX1 3PU UK — $[\text{Cu}(\text{VF}_6)(\text{pyz})_2] \bullet 4\text{H}_2\text{O}$ (**1**) and $[\text{Cu}(\text{HF}_2)(\text{pyz})_2]\text{SbF}_6$ (**2**) form tetragonal frameworks that consist of 2D $[\text{Cu}(\text{pyz})_2]^{2+}$ square lattices that are linked in 3D by bridging VF_6^{2-} (**1**) or HF_2^- (**2**) anions. Magnetic susceptibility data shows apparent paramagnetism, although not simple Curie-Weiss behavior, in **1**. For **2**, a broad maximum in $\chi(T)$ at 12.5 K and a sharp kink at 4.3 K indicate short- (SRO) and long-range (LRO) magnetic ordering, respectively. Additional experimental data for **1** (e.g., heat capacity and $\mu^+\text{SR}$) however, indicate that a LRO state occurs below 3.6 K whereas pulsed-field magnetization data suggest a superposition of AFM Cu^{2+} layers and fluctuating V^{4+} moments. The structural and magnetic behavior of **1** and **2** will be described as well as possible new directions.

4:06PM T13.00009 ABSTRACT WITHDRAWN —

4:18PM T13.00010 Strong Exchange Anisotropy in Heavy Atom Radical Ferromagnets¹, STEPHEN WINTER, University of Waterloo — The discovery twenty years ago of ferromagnetic ordering in “light atom” p-block (N, O based) radicals appeared to provide a major conceptual advance, suggesting the possibility of a new era in non-metal molecular magnetism. However, the weak through-space magnetic exchange interactions present in these early radical-based ferromagnets afforded very low Curie temperatures T_C (< 2 K), and the localization of spin density on light atoms ensured low coercive fields H_c (< 100 Oe). In this context, the observation of ferromagnetic ordering in “heavy atom” (Se) radicals, with T_C as high as 17 K and coercive fields H_c up to 1370 Oe (at 2 K), represents a significant improvement in properties. This presentation will provide a theoretical and experimental examination of the source of the large coercive fields reported for these “heavy atom” radical ferromagnets. High-field ferromagnetic resonance (FMR) measurements, interpreted in the context of the anisotropic exchange interactions between the radicals in the solid state, leads to the conclusion that spin-orbit effects are responsible for the large observed magnetic anisotropy. This conclusion is supported by detailed analysis of the symmetry and magnitude of the spin-orbit interactions. An interesting discussion is the extent to which these anisotropic exchange terms also contribute to the enhancement of T_C . That is, in the field of organic magnetism, where low dimensional magnetic structures are commonly found, long range ordering may depend crucially on such anisotropy.

4:54PM T13.00011 FMR Study of the Field Dependence of the Ferromagnetic Transition in an Organic Magnet, ALEXEY KOVALEV, NHMFL, Tallahassee, FL32310, STEPHEN WINTER, University of Waterloo, Ontario N2L 3G1, Canada, STEPHEN HILL, NHMFL and Florida State University, Tallahassee, FL32310, RICHARD OAKLEY, University of Waterloo, Ontario N2L 3G1, Canada — Organic heterocyclic thia/selenazyl radicals have unique magnetic properties. First and foremost, in their crystalline form, they experience a transition to a ferromagnetic state at temperatures that are the highest for any material containing only non-metallic elements. Second, their low temperature uniaxial anisotropy field is the highest among purely organic ferromagnets [Winter et al., JACS 133, 8126 (2011)]. To investigate the effect of a magnetic field on the transition in the mixed Se-S compound ($T_c = 12.5$ K) at zero field, we employ ferromagnetic resonance (FMR) absorption as a measure of the anisotropy field for a single crystal. We also focus on the temperature and field dependence of the FMR linewidth. Our main finding is that the application of a field significantly broadens the ferromagnetic transition, with a noticeable FMR signal observed to as high as $2T_c$ in fields of a few tesla. Meanwhile, the FMR linewidth is relatively insensitive to frequency/field, though it becomes narrower upon decreasing the temperature and saturates below T_c . We will discuss the broadening of the ferromagnetic transition within the framework of scaling theory.

Session T14 GMAG DMP FIAP: Focus Session: Spins in Semiconductors - Spins and Edge States 212

2:30PM T14.00001 Controlled coupling of spin-resolved quantum Hall edge states, BISWAJIT KARMAKAR¹, NEST-CNR Istituto Nanoscienze and Scuola Normale Superiore. Pisa. Italy — Spin resolved edge states in quantum Hall systems at filling fraction $\nu = 2$ possess large coherence [1] and relaxation [2] lengths. They are ideal candidates for the implementation of dual-rail quantum computation architectures [3] by encoding the qubit in the spin degree of freedom of the co-propagating spin resolved edge states. An important element for realization of such architectures is a coherent beam splitter that controllably mixes the two co-propagating spin-resolved edge channels to create any superposition of the two logic states. In this talk we demonstrate a new method to controllably couple spin resolved edge states and induce inter-edge charge transfer associated to spin-flip scattering events [4]. The process exploits the coupling of the electron spin with a spatially-dependent periodic in-plane magnetic field that is created by an array of Cobalt nano-magnets placed at the boundary of the GaAs/AlGaAs modulation doped heterostructure. The maximum charge/spin transfer of 28 ± 1 % is achieved at 250 mK by fine tuning the perpendicular magnetic field. These results are key steps towards the realization of a scalable quantum interferometric device currently under investigation in our group.

3:06PM T14.00002 Theory of Temperature-dependent Spin Dynamics with Electron-Phonon Interaction, JIMMY HUTASOIT, TUDOR STANESCU, West Virginia University — We develop a theory of temperature-dependent spin dynamics in spin-orbit coupled semiconductors that includes the effects of electron-phonon interaction. A set of coupled kinetic equations for the spin density matrix are derived starting from the quantum Liouville equation. The spin-conserving and spin-flipping scattering terms due to electron-phonon interaction in the presence of spin-orbit coupling are derived explicitly using an effective low-energy Hamiltonian for the conduction and valence bands. From the solution of the kinetic equations, we extract the temperature dependence of spin transport and relaxation in various parameter regimes. In particular, we discuss the effect of electron-phonon interaction on the persistent spin helix lifetime.

3:18PM T14.00003 Absence of intrinsic spin splitting in 1D quantum wires of tetrahedral semiconductors¹, JUN-WEI LUO, LIJUN ZHANG, National Renewable Energy Laboratory, Golden, Colorado 80401, USA, ALEX ZUNGER, University of Colorado, Boulder, Colorado 80309, USA — The energy bands of 3D, 2D, and 1D structures are generally split at certain wavevector values into spin-components, a spin splitting that occurs even without external magnetic field and reflects the effect of spin-orbit interaction on certain symmetries. We show via atomistic theory that 1D quantum-wires made of conventional zincblende semiconductors have unexpected zero SS for all electron and hole bands if the wire is oriented along (001) (belonging to D_{2d} symmetry), and for some of bands if the wire is oriented along (111) (belonging to C_{3v} symmetry). We find that the predicted absence of Dresselhaus SS in both (001)-oriented and (111)-oriented 1D wires is immune to perturbations lowering their original D_{2d} and C_{3v} structural symmetries, such as alloying of the matrix around the wire or application of an external electric field. Indeed, such perturbations induce only Rashba SS. We find that the scaling of the SS with wavevector is dominated by a linear term plus a minor cubic term.

3:30PM T14.00004 chiral magnon edge mode in a magnonic crystal, RYUICHI SHINDOU, RYO MATSUMOTO, SHUICHI MURAKAMI, Tokyo Institute of Technology — A bosonic system with a periodically crystalline potential has a Chern integer associated with its magnetic Bloch wavefunction. As in its fermionic counterpart like integer quantum Hall states, the Chern number thus introduced is defined for each bosonic energy band which is energetically separated from the others. When two bosonic systems having different Chern integers are connected, or when a bosonic system with non-zero Chern integer is terminated with the vacuum, chiral bosonic edge modes appear in their boundaries. We argue that a simple magnonic crystal can realize such magnonic chiral edge modes. Based on this example, we show how to design spin-wave guides in a magnonic crystal and how to channelize, split and manipulate them.

3:42PM T14.00005 Anomalous Hall and Nernst effects in electron and hole-doped semiconductors, EUGEN DUMITRESCU, CATALINA MARINESCU, Clemson University, CHUANWEI ZHANG, Washington State University, SUMANTA TEWARI, Clemson University — Recently it has been proposed that Majorana fermions may exist in a thin film semiconductor with proximity induced s-wave superconductivity. We compute anomalous Hall and anomalous Nernst coefficients for both electron and hole-doped semiconducting systems in the presence of an in-plane magnetic field and Rashba and Dresselhaus spin-orbit coupling. The anomalous Nernst coefficient vanishes and has plateaus as a function of the chemical potential corresponding to carrier densities which realize the topological state.

3:54PM T14.00006 The Origin of Dirac Cones for Classical Waves in Periodic Systems, JUN MEI, Department of Physics, South China University of Technology, Guangzhou 510641, China, YING WU, Division of Mathematical and Computer Sciences and Engineering, King Abdullah University of Science and Technology, Thuwal 23955-6900, Saudi Arabia, CHE TING CHAN, ZHAO-QING ZHANG, Department of Physics and William Mong Institute of Nano Science and Technology, Hong Kong University of Science and Technology, Hong Kong — By using a perturbation method, we propose a general theory to understand the origin of Dirac cone dispersions for classical waves in periodic structures. A selection rule for the existence of Dirac cones is established under the group theory analysis, which reveals the relation between the unusual linear dispersions and the symmetry of the degenerate Bloch states at the Dirac point. The theory is capable of accurately predicting the linear slopes at various symmetry points in the Brillouin zone, independent of frequency and lattice structure. Furthermore, it can be also used to construct the Hamiltonian, which is in consistent with the Berry phase calculations.

4:06PM T14.00007 Exactly Solvable Topological Chiral Spin Liquid with Random Exchange¹, VICTOR CHUA, GREGORY A. FIETE, Department of Physics, University of Texas at Austin — We extend the Yao-Kivelson decorated honeycomb lattice Kitaev model [Phys. Rev. Lett. 99, 247203 (2007)] of an exactly solvable chiral spin liquid by including disordered exchange couplings. We have determined the phase diagram of this system and found that disorder enlarges the region of the topological non-Abelian phase with finite Chern number. We study the energy level statistics as a function of disorder and other parameters in the Hamiltonian, and show that the phase transition between the non-Abelian and Abelian phases of the model at large disorder can be associated with pair annihilation of extended states at zero energy. Analogies to integer quantum Hall systems, topological Anderson insulators, and disordered topological Chern insulators are discussed.

4:18PM T14.00008 Lie algebras for time-dependent Rashba-Dresselhaus materials, JEAN-FRANCOIS VAN HUELE, MANUEL BERRONDO, Brigham Young University — We study the spin dynamics of Rashba and Dresselhaus interactions in systems with unconfined and confined geometries. We show how Lie algebra factorization of the evolution can be used to describe systems with arbitrary time-dependence in the parameters.

4:30PM T14.00009 Quantum Spin Holography with Surface State Electrons, OLEG BROVKO, VALERI S. STEPANYUK, Max Planck Institute of Microstructure Physics, Halle, Germany — Recently Moon et al. have shown that information can be stored in a fermionic state of a two-dimensional electron gas and have dubbed the proposed concept quantum holographic encoding. They have constructed molecular holograms of CO molecules on a Cu(111) surface, hosting a surface state (SS) [2]. Interference of electron waves scattered at the molecules leads to formation of an electron density pattern representing an information page [1]. This page has then been read out with an STM. It has been also shown that using the innate energy dispersion of SS electrons one can project the hologram not only in two spatial degrees of freedom but also in the energy dimension. In our contribution we expand the concept and show that the spin of the electron can also act as a new dimension for information storage. If the molecules or atoms used for a hologram are magnetic then the scattering of surface state electrons becomes spin-dependent, allowing one to store different information pages in different spin channels. As an example we demonstrate the possibility of simultaneous encoding two different information pages with electrons of the same energy but opposite spins.

2:30PM T15.00001 Investigation of CoO/Fe/Ag(001) and NiO/Fe/Ag(001) epitaxial thin films X-ray magnetic dichroism, Z.Q. QIU, University of California at Berkeley — Interfacial coupling at antiferromagnetic (AFM)/ferromagnetic (FM) interface is less understood because of the so-called magnetic frustration and the lack of direct measurement on AFM thin films. These difficulties have been partially overcome by recent development of X-ray Magnetic Dichroism on single crystalline magnetic thin films. In this talk, I will report our study on epitaxial CoO/Fe/Ag(001) system using X-ray Magnetic Circular Dichroism (XMCD) and X-ray Magnetic Linear Dichroism (XMLD). XMCD was used to measure the Fe hysteresis loops and XMLD was used to measure the response of the AFM CoO spins in response to the Fe magnetization reversal. We find that the CoO spins consist of rotatable and frozen spins with respect to the Fe spin rotation, and only the Fe uniaxial magnetic anisotropy follows the CoO frozen spins. By using focused ion beam to pattern the films into microstructures, we also observed vortex state in CoO disk imprinted from the Fe vortex state.

3:06PM T15.00002 Mirror symmetry in magnetization reversal and coexistence of positive and negative exchange bias in Ni/FeF₂ heterostructures, XAVIER BATLLE, M. KOVYLINA, A. LABARTA, Dept. Fisica Fonamental, Universitat de Barcelona, 08028 Barcelona, Catalonia, Spain, R. MORALES, Basque Foundation for Science, IKERBASQUE, 48011 Bilbao, Spain, M. EREKHINSKY, IVAN K. SCHULLER, Physics Department, University of California San Diego, La Jolla 92093 CA, USA — Positively and negatively exchange biased (PEB and NEB) magnetoresistance (MR) loops in Ni/FeF₂ ferromagnetic/antiferromagnetic (AF) heterostructures proceed through exactly the same reversal mechanisms. The MR curves exhibit striking mirror symmetry: the increasing (decreasing) field branch of the PEB (NEB) loop is identical to the decreasing (increasing) branch of the NEB (PEB) loop. The latter suggests that, on average, similar but opposite sign EB domain configurations are reached for low or high cooling fields, with equal interfacial density of pinned uncompensated AF spins responsible for NEB or PEB. Micromagnetic simulations are in agreement with experimental results and imply the coexistence of EB domains of opposite sign for all cooling fields, which results in a new reversal mechanism not previously reported. The persistence of NEB (PEB) domains even at high (low) cooling fields may be produced by the size distribution and density of pinned uncompensated moments in the bulk of the AF. The support of the Spanish MICINN, Catalan DURSI, IKERBASQUE and the US Department of Energy are recognized.

3:18PM T15.00003 Phase separation and giant exchange bias in Mn-based binary alloys¹, F. JIMENEZ-VILLACORTA, J.L. MARION, L.H. LEWIS, Department of Chemical Engineering, Northeastern University — The ability to tailor, control and modify the magnetic properties of Mn-based alloys opens the possibility of developing exchange bias systems for permanent magnet and sensor technologies. Rapid solidification of AgMn, CuMn and AlMn manganese-based alloys, with significant Mn concentration (~ 30 -70 at%), has produced alloys that all exhibit a remarkable exchange bias at $T = 10$ K, of the order of ~ 10 kOe. Structural characterization confirms the formation of a phase-separated nanostructure (*fcc* for AgMn and CuMn and *hcp* for AlMn) of 40-80 nm in all alloys as characterized by phase-specific crystallographic texture and lattice parameters. The observed exchange bias is highly reduced upon moderate annealing ($T = 250$ °C) accompanied by homogenization of the Mn concentrations in the alloys. These results are tentatively attributed to different metastable incorporation of Mn within the two phases, yielding slightly different unit cell volumes, which provides an antiferromagnetic (Mn-rich phase) and ferromagnetic (Mn-poor phase) character in these two phases.

¹This research has been funded by the Office of Naval Research (ONR) under Grant # N00014-10-1-0553.

3:30PM T15.00004 Exchange Bias and Large Vertical Magnetization Shift in FM/V₂O₃ Interfaces¹, JOSE DE LA VENTA, MIKHAIL EREKHINSKY, SIMING WANG, IVAN K. SCHULLER, Univ of California - San Diego, RAFAEL MORALES, Universidad del País Vasco and IKERBASQUE — We have investigated exchange bias in different combinations of V₂O₃ thin films with ferromagnetic layers. The exchange bias is accompanied by a large vertical shift in the magnetization. These effects are only observed when V₂O₃ is grown on top of Ni₈₀Fe₂₀ permalloy (Py). The magnitude of the vertical shift is as large as 60% of the total magnetization which has never been reported in any system. The exchange bias and the vertical shift are related to the formation of a Fe₃O₄ interlayer. We will show evidence that the Fe₃O₄ Verwey transition is responsible for the appearance of the exchange bias and the vertical shift in the magnetization.

3:42PM T15.00005 Exchange Bias in Ni/Co Multilayers with Perpendicular Anisotropy¹, SCOTT M. CAMPBELL, Department of Physics, University of South Florida, S.M. MOHSENI², T.N. ANH NGUYEN, Materials Physics, School of Information and Communication Technology, KTH Royal Institute of Technology, R.K. DUMAS, JOHAN AKERMAN³, Department of Physics, University of Gothenburg, CASEY W. MILLER, Department of Physics, University of South Florida — We have studied exchange bias in Ta(5nm)/Au(10)/[Ni(t)/Co(0.4)] $\times$ 5/IrMn(8)/Ta(5) multilayers for Ni thicknesses of 0.8-1.2 nm. The samples were deposited via sputtering and no deposition field was used. The samples were annealed at 200 °C in an applied field of 1500 Oe for different durations, then measured by polar Magneto-Optical Kerr Effect at room temperature. We find that the field annealing significantly alters the hysteresis loop shape, giving it more single domain character while simultaneously inducing exchange bias in the direction of the annealing field. After 34 (2 and 32) hrs annealing, the exchange bias of the samples each reach a maximum value ranging from 100 Oe for the thickest Ni to 35 Oe for the thinnest Ni. We find that the samples with the thinner Ni layers approach their exchange bias maximum values for shorter annealing times.

3:54PM T15.00006 Electrical measurement of antiferromagnetic moments in exchange-coupled IrMn/NiFe stacks, H. REICHOVA, X. MARTI, Institute of Physics ASCR, v.v.i., Cukrovarnicka 10, Praha 6, Czech Republic, B.G. PARK, J. WUNDERLICH, Hitachi Cambridge Laboratory, Cambridge CB3 0HE, UK, Y. KUROSAKI, M. YAMADA, H. YAMAMOTO, A. NISHIDE, J. HAYAKAWA, H. TAKAHASHI, Hitachi Ltd, Advanced Research Laboratory, 1-280 Higashi-koigakubo, Kokubunju-shi, Tokyo 185-8601, Japan, T. JUNGWIRTH, Institute of Physics ASCR, v.v.i., Cukrovarnicka 10, Praha 6, Czech Republic — A great attention is currently focused on the development of new spintronic devices. One crucial technological issue is the coupling phenomena between thin antiferromagnetic (AFM) and ferromagnetic (FM) layers. Despite the exchange coupling was for the first time observed already in 1956, yet the effect is not fully understood. Certainly, the zero macroscopic magnetic moment in the AFM materials hinders the investigation, in contrast to the exhaustive studies on the FM counterpart. Only a very few experiments at large scale facilities explored the status of the AFM layer. Here, we will address the study of both FM and AFM moments in the archetypical IrMn/NiFe exchange-coupled system. Using common laboratory magnetization and transport tools, we found a direct link between reversal of FM moments in NiFe and rotation and pinning of AFM moments in IrMn [1]. We will show that a full rotation of AFM moments in IrMn occurs at high temperatures, in contrast to only partial rotation of AFM at low temperatures. We will discuss the experimental results in the framework of different exchange coupling models. [1] <http://arxiv.org/abs/1108.2189>

4:06PM T15.00007 Exchange bias of conetic thin films¹, TATIANA EGGERS, HILLARY KIRBY, PRIYANGA JAY-ATHILAKA, SCOTT CAMPBELL, CASEY MILLER, University of South Florida — In this work, we study the exchange bias and coercivity of Ni₇₇Fe₁₄Cu₅Mo₄ (Conetic, also known as mu-metal) exchange coupled with FeMn as functions of Conetic thickness and buffer layer material. The samples studied were BL(30nm)/Conetic(9nm-30nm)/FeMn(10nm)/Ta(5nm), where BL = Cu or Ta. All samples were grown by magnetron sputtering in a deposition field of ~ 150 Oe during growth to set the exchange bias axis. Room temperature hysteresis loops were measured by a magneto-optical Kerr effect magnetometer as a function of applied-field angle. For each variety of sample, the exchange bias and coercivity were inversely proportional to Conetic thickness. With Cu buffer layers grown on Si, the H_{eb} decreased from 300 Oe to 62 Oe, and H_c decreased from 99 Oe to 9 Oe. Similar results were found when the Cu buffer layer was grown on SiO_x, though the maximum coercivity was only 67 Oe. For the samples grown on Si(001)/Ta(5nm), the exchange bias decreased from 80 Oe to 14 Oe, while the coercivity increases only slightly from 2 Oe to 10 Oe. These results indicate a trade-off between preserving the softness of the ferromagnet and having a large exchange, which may be useful for tuning the performance of low-field sensing materials

4:18PM T15.00008 Effect of Cu Layer on Exchange Bias in FeMn, DOGAN KAYA, Texas A&M University, PRIYANGA JAYATHILAKA, CASEY W. MILLER, University of South Florida, IGOR V. ROSHCHIN, Texas A&M University — One of the most important puzzles related to the mechanism of exchange bias is the origin and role of uncompensated magnetization in the antiferromagnet. We study effects of a Cu layer on the uncompensated magnetization and exchange bias in FeMn, the material with a high potential for applications in magnetic recording. The multilayers of Ta(50 Å)/[FeMn(50 Å – 150 Å)/Cu(50 Å)]₁₀/Ta(50 Å) are deposited by UHV DC magnetron sputtering on top of Si/SiO_x 3 mm x5 mm substrates. Samples with a single layer of FeMn of the same thickness, Ta(50 Å)/FeMn(50 Å – 150 Å)/Ta(50 Å) are used as control samples. The samples are cooled in a field of 7 T and their magnetization is measured using a SQUID magnetometer. All the samples have uncompensated magnetization that exhibits a hysteresis at 10 K. The hysteresis loops for FeMn/Cu multilayers are exchange bias shifted, while FeMn without Cu exhibits no exchange bias. Dependence of coercive field (H_c), exchange bias (H_e), and saturated magnetization (M_s) on the FeMn thickness and on temperature will be discussed. Work is supported by Texas A&M University, TAMU-CONACYT Collaborative Research Program, and by NSF (USF).

4:30PM T15.00009 Interface coupling between ferromagnets and random and dilute antiferromagnets¹, DAVID LEDERMAN, KINESHMA MUNBODH, MIYEON CHEON, West Virginia University, Morgantown, WV 26506-6315, M.R. FITZSIMMONS, Los Alamos National Laboratory, Los Alamos, NM 87545, NEIL R. DILLEY, Quantum Design, Inc., San Diego, CA 92121 — Depth profiles for pinned and unpinned magnetizations were determined across the interface between a ferromagnet (F) and random and dilute antiferromagnets (RAF and DAF) exemplified by $\text{Fe}_{0.45}\text{Ni}_{0.55}\text{F}_2/\text{Co}$ and $\text{Fe}_{0.34}\text{Zn}_{0.66}\text{F}_2/\text{Co}$ bilayers, respectively, using polarized neutron reflectivity (PNR). PNR measurements were complemented by magnetometry using applied fields as large as 160 kOe to assure saturation of the entire sample, including magnetic moments that are normally pinned at lower fields. The locations of pinned and unpinned magnetization in the ferro- and antiferromagnets were identified. The origin of exchange bias in the RAF system is noticeably different than that of the DAF system. In the RAF system, a domain wall is formed at the RAF/F interface when the ferromagnet's magnetization is reversed. In the DAF system, some domains within the bulk of the DAF are reversed upon reversal of the ferromagnet with others remaining pinned, while the interface magnetization is entirely reversed. This work was supported by the National Science Foundation.

4:42PM T15.00010 A study of the magnetic interlayer coupling between CoO(NiO) and Fe films across MgO spacer layer in CoO(NiO)/MgO/Fe/Ag(001) using MOKE and XMLD, ALI TAN, JIA LI, YANG MENG, University of California Berkeley, ELKE ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, CHANYONG HWANG, Advanced Industrial Technology Group, Korea Research Institute of Standards and Sciences, ZI QIANG QIU, University of California Berkeley — CoO(NiO)/MgO/Fe/Ag(001) films were grown epitaxially and studied by Magneto Optical Kerr Effect (MOKE) and X-ray Magnetic Linear Dichroism (XMLD). The enhancement of the Fe layer coercivity due to its coupling to the AFM (NiO) overlayer was studied as a function of the MgO spacer layer thickness using MOKE. We found that the Fe coercivity enhancement persists to ~ 2 ML MgO thickness, after which the AFM-FM interlayer coupling becomes too weak to affect the Fe coercivity. Below 2ML MgO thickness, the Fe coercivity enhancement depends both on the MgO and NiO thicknesses. To further understand the effect of interlayer coupling, the rotatable CoO spins in CoO/MgO/Fe/Ag(001) after field cooling along the Fe(100) axis were determined using the XMLD measurement as a function of the MgO thickness. We found that 2 ML MgO thickness sets a critical value beyond which the CoO/MgO/Fe interlayer coupling no longer rotates the CoO spins.

4:54PM T15.00011 Modification of thickness dependent magnetic properties of perpendicular anisotropy Co/Pd multilayer upon hydrogenation¹, KINESHMA MUNBODH, FELIO PEREZ, DAVID LEDERMAN, West Virginia University — We have studied the change in saturation magnetization (M_S) and effective perpendicular anisotropy (K_{eff}) upon hydrogenation at room temperature and a pressure of one atmosphere in (Co/Pd)₂₅ multilayers, with Co thickness ≤ 5 Å and Pd thickness ranging from 0 Å to 25 Å. The change in M_S and K_{eff} was studied as a function of the x-ray scattering length density profile, generated from the x-ray reflectivity fits. The results show that when the Pd thickness ≤ 10 Å, the films were highly interdiffused, resulting in no measurable change in M_S and K_{eff} . As the thickness of Pd increases, the contrast between the Co and Pd layers increases, leading to a decrease in M_S and an increase in the component of magnetization in the plane of the samples and hence causing K_{eff} to decrease. The results clearly demonstrate that the solubility of hydrogen in the multilayer samples decreases with increasing alloying effects as it decreases the vacancy in the Pd 4d band leading to no electronic transfer from the hydrogen atoms to the Pd.

5:06PM T15.00012 Momentum transfer resolved memory in a magnetic system with perpendicular anisotropy, KEOKI SEU, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, RUN SU, DAN PARKS, Physics Department, University of Oregon, ERIK SHIPTON, ERIC FULLERTON, Physics Department, University of California at San Diego, STEPHEN KEVAN, Physics Department, University of Oregon — We have used resonant, coherent soft x-ray scattering to measure wave vector resolved magnetic domain memory in Co/Pd multilayers. The technique uses angular cross correlation functions and can be applied to any system with circular annuli of constant values of scattering wave vector q . In our Co/Pd film, the memory exhibits a maximum at $q=0.0384$ nm⁻¹ near initial reversal that decreases in magnitude as the magnetization is further reversed. The peak is attributed to bubble domains that nucleate reproducibly near initial reversal and which grow into a labyrinth domain structure that is not reproduced from one magnetization cycle to the next.

5:18PM T15.00013 Measure of magnetization anisotropy by AMR in electrodes of Co/Pd multilayers¹, AMOS SHARONI, YANIV KACHLON, NOA KURZWEL, Department of Physics and Institute of Nanotechnology, Bar Ilan University, Ramat Gan, Israel — We studied the anisotropic magnetoresistance (AMR) properties of multilayered Co/Pd thin film electrodes as function of magnetic field. The perpendicular magnetization anisotropy (PMA) in these films is found to modify the AMR. The magnetoresistance (MR) for fields out-of-plane (ρ_{op}) is considerably different than for in-plane fields transverse to current direction (ρ_{ip}), although in both cases current is perpendicular to the magnetic field. Moreover, opposed to other thin films, where ρ_{op} is smaller than ρ_{ip} , our films show an opposite effect, the origin of which is not clear. We can understand the AMR properties of the electrodes by an expanded Stoner-Wolfarth model, where we introduce an additional energy scale related to the PMA. Through a numerical refinement process, we can extract anisotropic energy constants of the films. This is done by reconstructing the MR behavior of the electrodes, using the linear terms in the dependence of resistivity on magnetization orientation. Our anisotropic constants coincide remarkably with other bulk measurements. Thus, our refinement process is an excellent method to extract anisotropic constants also in nano-scale systems, which cannot be measured otherwise.

Wednesday, February 29, 2012 2:30PM - 5:30PM — Session T16 DCMP: Kondo Lattice Theory 251

2:30PM T16.00001 A new paradigm for heavy electron materials, YI-FENG YANG, Institute of Physics, Chinese Academy of Sciences, DAVID PINES, University of California, Davis — Recent experiments on the emergence of heavy electrons that display universal behavior below a characteristic temperature T^* have shown that the well-known Doniach phase diagram does not apply to most materials. Here we introduce the concept of hybridization effectiveness as the organizing principle and show that it makes possible a consistent and quantitative description of the low temperature emergent behaviors of a number of heavy electron materials. We propose a new phase diagram and predict a delocalization line in the pressure/temperature phase diagram that is to be examined in future experiment.

2:42PM T16.00002 Superconductivity in Heavy Fermion Materials, JOHN VAN DYKE, JEREMY FIGGINS, DIRK MORR, University of Illinois at Chicago — Superconductivity in heavy fermion materials is a complex phenomenon since it often emerges from a strongly entangled state, the Kondo screened heavy Fermi liquid. In this talk, we discuss possible pairing interactions that arises in the heavy Fermi liquid, and the resulting symmetries and momentum dependencies of the superconducting order parameter. In particular, we show that the interplay between the large Fermi surface of the Fermi liquid state and the momentum dependence of the pairing interaction naturally leads to an unconventional symmetry of the superconducting order parameter in general, and a $d_{x^2-y^2}$ -symmetry in particular. Moreover, we identify the signatures of unconventional pairing in the differential conductance, dI/dV , measured in scanning tunneling spectroscopy as well as in the quasi-particle interference pattern. Finally, we discuss the effects of impurities on the spatial dependence of both the superconducting order parameter and the hybridization.

2:54PM T16.00003 Single-particle and optical self-energies of a Fermi liquid revisited, DMITRII MASLOV, University of Florida, ANDREY CHUBUKOV, University of Wisconsin — We discuss the conditions under which the imaginary part of the single-particle self-energy at the Fermi surface $\Sigma(\omega, T)$ and the optical scattering rate $1/\tau(\Omega, T)$ have particular simple scaling forms $\text{Im}\Sigma(\omega, T) \propto \omega^2 + \pi^2 T^2$ and $1/\tau(\Omega, T) \propto \Omega^2 + 4\pi^2 T^2$. We show that these relations follow from particular analytic properties of the effective fermion-fermion interaction and are only satisfied when the single-particle and optical self-energies are analytic functions of the frequency. When they are not, the scaling forms are more complex even if the system remains a Fermi liquid. We also address recently observed violation of the $\Omega^2 + 4\pi^2 T^2$ form of $1/\tau$ in URu_2Si_2 and discuss possible mechanisms of this violation.

3:06PM T16.00004 Singular Valence Fluctuations at a Kondo Destroyed Quantum Critical Point¹, JEDEDIAH PIXLEY, Rice University, STEFAN KIRCHNER, Max Planck Institute for the Physics of Complex Systems, KEVIN INGERSENT, University of Florida, QIMIAO SI, Rice University — Recent experiments on the heavy fermion superconductor $\beta\text{-YbAlB}_4$ have indicated that this compound satisfies quantum critical scaling [1]. Motivated by the observation of mixed valency in this material [2], we study the Kondo destruction physics in the mixed-valence regime [3] of a particle-hole asymmetric Anderson impurity model with a pseudogapped density of states. In the vicinity of the quantum critical point we determine the finite temperature spin and charge susceptibilities by utilizing a continuous time quantum Monte Carlo method [4] and the numerical renormalization group. We show that this mixed-valence quantum critical point displays a Kondo breakdown effect. Furthermore, we find that both dynamic spin and charge susceptibilities obey frequency over temperature scaling, and that the static charge susceptibility diverges with a universal exponent. Possible implications of our results for $\beta\text{-YbAlB}_4$ are discussed. [1] Matsumoto et al, Science **331**, 316 (2011). [2] Okawa et al, Physical Review Letters **104**, 247201 (2010). 3:18PM T16.00005 Kondo Physics in a Rare Earth Ion with well localized $4f$ electrons¹, JOLANTA STANKIEWICZ, Instituto de Ciencia de Materiales de Aragon, CSIC-Universidad de Zaragoza, ZACHARY FISK, Department of Physics, University of California at Irvine, MARCO EVANGELISTI, Instituto de Ciencia de Materiales de Aragon, CSIC-Universidad de Zaragoza, PEDRO SCHLOTTMAN, Department of Physics, Florida State University — We observe a rise in the low temperature resistivity of dilute $\text{La}_{1-x}\text{Nd}_x\text{B}_6$ single crystals. The specific heat data for the same samples show that there is an entropy of $R\ln 4$ per mole Nd involved in the excess specific heat above that of LaB_6 . All these features are consistent with a Kondo scale of $T_K = 1$ K. However, Nd has a well localized $4f^3$ $J = 9/2$ Hund's Rule configuration which is not expected to be Kondo coupled to the conduction electrons in LaB_6 . We conjecture that the unexpected Kondo effect arises via participation of $4f$ quadrupolar degrees of freedom of the Nd crystal field ground state quartet. Raman experiments as well as detailed theoretical studies do indicate that one expects strong quadrupolar influence in the properties of NdB_6 .

3:30PM T16.00006 Partial disorder in the periodic Anderson model on a triangular lattice, SATORU HAYAMI, Dep. Appl. Phys., Univ. Tokyo, MASAFUMI UDAGAWA, Dep. Appl. Phys., Univ. Tokyo, MPI PKS, YUKITOSHI MOTOME, Dep. Appl. Phys., Univ. Tokyo — In Kondo lattice systems, keen competition between the Kondo coupling and RKKY interaction leads to a quantum critical point between a magnetically-ordered state and a Fermi liquid state. This is a source of novel phenomena, such as a non-Fermi liquid behavior and a superconductivity. In the present study, we explore a new quantum phase related to the competition by introducing a new parameter, geometrical frustration of the lattice structure. Especially, we focus on the possibility of a partial disordered (PD) state, in which a magnetically ordered and nonmagnetic sites coexist. We consider a fundamental model for the rare-earth systems, a periodic Anderson model on a frustrated triangular lattice, and investigate the ground-state phase diagram by the Hartree-Fock approximation with assuming three-site unit cell. As a result, we find a PD state at half filling between a noncollinear antiferromagnetic metal and a Kondo insulator [1]. The PD state is stabilized by relaxing the frustration by forming collinear antiferromagnetic order on an unfrustrated honeycomb subnetwork, while leaving remaining sites non-magnetic. We will also discuss the effects of spin anisotropy and carrier doping to the PD state.

3:42PM T16.00007 Quantum critical Kondo destruction of the Bose-Fermi Kondo model in the presence of a local transverse field, EMILIAN NICA, Rice University, KEVIN INGERSENT, University of Florida, QIMIAO SI, Rice University — Recent studies of the global phase diagram of quantum critical heavy fermion metals [1] have motivated us to consider the interplay between the quantum fluctuations within the local-moment system and those associated with the Kondo interaction. Towards this goal, we study a Bose-Fermi Kondo model with Ising anisotropy in the presence of a local transverse field. We apply the numerical renormalization group method for the case with a sub-ohmic bosonic bath exponent and a constant conduction electron density of states [2]. Upon increasing the strength of the transverse field in the Kondo screened phase we find a crossover from a fully screened to a fully polarized impurity spin with no transition in between. Increasing the strength of the transverse coupling in the localized phase, on the other hand, we identify signatures for a continuous transition into a partially polarized Kondo phase. We discuss the implications of our results for the global phase diagram of the Kondo lattice system.

3:54PM T16.00008 A spin-selective Kondo-insulator: Cooperation between Ferromagnetism and Kondo-effect, ROBERT PETERS, NORIO KAWAKAMI, Kyoto University, THOMAS PRUSCHKE, University of Goettingen — Taking ferromagnetic heavy fermion compounds as motivation we analyze the mechanism stabilizing the ferromagnetic state in the antiferromagnetically coupled Kondo lattice model. We find that even for this ferromagnetic state Kondo screening plays an essential role in stabilizing the ferromagnetic state at zero temperature leading to very interesting properties: while the majority-spin electrons are metallic, the minority-spin electrons form an insulating state. We clarify that this state is due to partial Kondo screening, so that parts of the local moments are bound to the electrons, resulting in a dynamically-induced commensurability which is essential for producing the gap in the minority-spin electrons. We believe that the mechanism proposed here, the dynamically generated commensurability, is generic for the ferromagnetic phase in the antiferromagnetically coupled Kondo lattice model, thus providing new insights into the zero temperature physics for the Kondo lattice model.

4:06PM T16.00009 Phase diagram of half-filled $J_1 - J_2$ -Heisenberg Kondo lattice model on honeycomb lattice¹

, QIMIAO SI, Rice University, PALLAB GOSWAMI, National High Magnetic Field Laboratory and Florida State University — Recent studies in quantum critical heavy fermion metals have opened up a rich phase diagram. The zero-temperature global phase diagram involves a combination of phases, featuring Kondo screening/destruction and antiferromagnetic order/disorder as the quantum fluctuations of the local moments are tuned relative to their Kondo coupling with the spins of the conduction electrons. Recently, we have studied a one-dimensional Heisenberg-Kondo model to reveal a competition between a Kondo-screened paramagnetic phase with a large Fermi surface and a Kondo-destroyed paramagnetic spin-Peierls phase with a small Fermi surface [1]. To take advantage of the intuitions gained through that work, we study here a half-filled, $J_1 - J_2$ Heisenberg-Kondo lattice model on a honeycomb lattice. We have obtained a rich phase diagram as a function of magnetic frustration and Kondo coupling. Apart from antiferromagnetic and Kondo insulators, we also find Kondo-destroyed phases that are semi-metallic with Fermi points. There are also particular critical points which are gapless in both charge and spin sectors.

4:18PM T16.00010 Cluster dynamical mean-field study of charge ordering in the Kondo lattice model at quarter filling

, JUNKI YOSHITAKE, TAKAHIRO MISAWA, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — The Kondo lattice model is one of fundamental models for heavy-fermion systems, where exchange interactions between itinerant electrons and localized spins play an important role. Among many different phases described by this model, an interesting possibility is a charge-ordered state, in particular when considering the fact that the model does not include any bare repulsive interaction between electrons. The possibility was first pointed out by a perturbation expansion in the strong Kondo coupling limit at quarter filling [1], and recently examined by the dynamical mean-field theory in infinite dimensions [2]. However, it remains unclear whether the charge-ordered state still survives in two or three dimensions and what type of magnetic order is accommodated in the charge-ordered state. To clarify these issues, we investigate the quarter-filled Kondo lattice model on a square lattice by using cluster dynamical mean-field theory, which can include both spatial and dynamical correlations. We found that charge-ordered state appears in the intermediate coupling region. We will discuss electronic and magnetic properties in the charge-ordered state in detail.

4:30PM T16.00011 Phase diagram of the non-centrosymmetric Kondo lattice model

, LEONID ISAEV, Louisiana State University, DANIEL AGTERBERG, University of Wisconsin-Milwaukee, ILYA VEKHTER, Louisiana State University — Kondo lattice model is prototypical for studying materials with localized f-electrons such as heavy-fermion compounds that exhibit a competition between Kondo screening and magnetism. This competition was argued to be crucial for superconductivity in these systems. We study the effects of spin-orbit interaction (SOI) in the conduction band (due to the lack of inversion symmetry), on the interplay between Kondo, superconducting and magnetic phases by considering the $S = 1/2$ 2D Kondo lattice with short-range Heisenberg coupling between localized moments and utilizing a pseudo-fermion hybridization mean-field theory. In particular, we demonstrate that the heavy-fermion state, and hence superconductivity, is suppressed with increasing SOI. Our results are of relevance for Ce- and U-based heavy-fermion superconductors without inversion symmetry.

4:42PM T16.00012 Simulation of the triangular Kondo-lattice model using the gradient kernel polynomial method

, KIPTON BARROS, YASUYUKI KATO, Theoretical Division, Los Alamos National Laboratory — We introduce a method to study systems, such as the Kondo-lattice model, where a classical field is coupled to fermionic degrees of freedom. Such systems are computationally challenging because each change to the classical field requires recalculation of the density of states for the bilinear fermionic Hamiltonian. The kernel polynomial method (KPM) is a useful tool to approximate the density of states at a cost linear in the system size. We extend KPM to approximate the gradient of the density of states at the same cost, allowing fast updates of the entire classical field. Simulations of the triangular Kondo-lattice model indicate phases with exotic non-coplanar spin ordering and spontaneous quantum Hall effect.

4:54PM T16.00013 Monte Carlo simulations of magnetic clustering at a quantum critical point¹

, TOM HEITMANN, University of Missouri Research Reactor, JOHN GADDY, JAGAT LAMSAL, WOUTER MONTFROOIJ, Department of Physics and Astronomy, University of Missouri — We present the results of Monte Carlo simulations on a percolating magnetic system with relevance to quantum critical point materials. It has previously been shown that, for heavily doped quantum critical point compounds such as $\text{Ce}(\text{Ru}_{0.24}\text{Fe}_{0.76})_2\text{Ge}_2$, the formation and dynamics of magnetic clusters strongly influences the physical response of the system at low temperature. Our simulation is based on the idea that finite-size effects force small magnetic clusters to order at comparatively high temperatures and, once formed, are impervious to Kondo shielding. Disorder acts to introduce a distribution of Kondo temperatures which, in turn, governs the formation of clusters as the temperature is lowered. We implement a percolation model based on such a distribution— first introduced by Bernal *et al.*— and with a restriction whereby Kondo shielding is allowed to remove moments from the infinite cluster *only*. We investigate how this influences thermodynamic quantities as well as how well the simulations align with our analytic theory that is based on the same restriction.

5:06PM T16.00014 Monte Carlo study of a spin-ice type Kondo lattice model on a pyrochlore lattice

, HIROAKI ISHIZUKA, Dept. of Appl. Phys., Univ. of Tokyo, MASAFUMI UDAGAWA, Dept. of Appl. Phys., Univ. of Tokyo, MPI-PKS, Dresden, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo — Recent experiments on geometrically frustrated metallic oxides, such as pyrochlore oxides $\text{R}_2\text{Mo}_2\text{O}_7$ and $\text{R}_2\text{Ir}_2\text{O}_7$, have drawn increasing interest in the effect of geometrical frustration in itinerant electron systems. In these systems, the coupling between electrons and frustrated magnetism leads to various fascinating phenomena. However, much less theoretical studies have been done by treating the interplay of localized spins and itinerant electrons in an unbiased manner. To clarify electronic and magnetic behaviors in such spin-charge coupled systems on frustrated lattice structures, we investigate a spin-ice type Kondo lattice model on a pyrochlore lattice by a real-space Monte Carlo simulation. By employing a sophisticated algorithm, we conduct calculations up to 2048 sites. We show that the system exhibits keen competition between various magnetic phases depending on the spin-charge coupling and electron density. As a consequence, the system shows rich phase diagram with complex magnetic orderings and phase separations between them. Furthermore, in applied magnetic field, we identify a magnetization plateau for one of the novel magnetic phases. In the presentation, the phase diagram and the mechanism of the magnetic orderings will be discussed in details.

5:18PM T16.00015 O(3)-symmetric variational wave functions for the Kondo lattice model

, JOHAN NILSSON, University of Gothenburg — We construct and investigate a class of correlated wave functions for the Kondo lattice model. The construction is based on the faithful fermionic representation of the Kondo lattice model that was introduced recently by the author in PRB **83**, 235103 (2011). In the limit of small exchange coupling the wave functions allow for both local singlet correlations between the localized moments and the conduction electrons, as well as an essentially arbitrary spin correlation function for the localized moments. We compare and contrast our results with those of previous studies.

2:30PM T17.00001 AC Bias Spectroscopy of the Kondo Singlet in a Single Electron Transistor¹

, BRYAN HEMINGWAY, TAI-MIN LIU², ANDREI KOGAN, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University — We have measured the nonlinear differential conductance, G , of a single electron transistor in the spin 1/2 Kondo regime in presence of an oscillating source voltage. In two distinct regimes, $hf > k_B T_K$ and $hf \ll k_B T_K$, where f is the oscillation frequency and T_K is the Kondo temperature, comparison to the static model of Kondo transport reveals agreement at very low frequencies and an increasing systematic departure at high frequencies. When $hf \lesssim k_B T_K$, the G defined as the derivative of the time averaged current through the device with respect to the average bias drastically differs from the static model. We show that the effect cannot be explained by an increase in the electron temperature.

2:42PM T17.00002 Connection between Local moment and Underscreened Kondo effect in parallel double quantum dots¹

, SERGIO ULLOA, NANCY SANDLER, Ohio U, ARTURO WONG, KEVIN INGERSENT, U of Florida, WILLIAM LANE, Jacksonville U, LUIS DIAS, U of Sao Paulo — Double quantum dots connected in parallel to a single channel, have been studied theoretically in two disparate limits: (I) Systems in which each dot has strong Coulomb interactions, exhibiting an underscreened spin-1 Kondo effect [1]; (II) An interacting dot 1 and a non-interacting dot 2, showing a quantum phase transition between Kondo phase and non-Kondo local-moment [2]. In this work, we use the numerical renormalization group approach to study a strongly interacting “quantum dot 1” and a weakly interacting “dot 2” connected in parallel to metallic leads. Gate voltages can drive the system between Kondo-quenched and free-moment phases separated by Kosterlitz-Thouless quantum phase transitions. As interactions in dot 2 become stronger relative to the dot-lead coupling, the free moment evolves from an isolated spin-1/2 in dot 1 to a many-body doublet arising from an underscreened Kondo effect. These limits, which feature very different entanglements between dot and lead electrons, can be distinguished by conductance measurements at finite temperatures.

2:54PM T17.00003 Temperature Dependence of a Double Quantum Dot Kondo Effect

, ANDREW J. KELLER, SAMI AMASHA, ILEANA G. RAU, Stanford University, JORDAN A. KATINE, Hitachi Global Storage Technologies, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDBABER-GORDON, Stanford University — Lateral quantum dots are highly tunable experimental systems ideal for exploring the interplay of orbital, spin, and charge correlations. We present studies of a double quantum dot system in a GaAs/AlGaAs heterostructure where transport through each dot may be measured independently. In the limit of negligible inter-dot tunneling, the conductance through both dots is enhanced along inter-dot charge degeneracy lines, where the energy cost for an electron to be on either dot is the same [A. Hübner, et al. PRL 101, 186804 (2008)]. With spin degeneracy, there are expected to be four or five-fold degenerate states, depending on the parity of the electron occupation number of each dot. We attribute the enhanced conductance to a double-dot Kondo effect that screens these localized, degenerate states. The temperature dependence of this Kondo effect is studied as a function of the coupling strength of each dot to its leads and the parity of the electron occupation numbers.

3:06PM T17.00004 Phase-dependent coherence and transport effects in a double-dot Aharonov-Bohm interferometer¹

, SAVANNAH GARMON, SALIL BEDKHAL, DVIRA SEGAL, University of Toronto — We study coherence dynamics between two sites comprising a double-dot interferometer attached to non-equilibrium leads. We demonstrate via numerical simulation that a magnetic flux passing through the interferometer results in phase-dependent decoherence in the case of degenerate dots. The precise details of these effects relies on an interplay between Markovian and non-Markovian dynamics. We employ various methods to further investigate these effects analytically, including the derivation of a quantum Langevin equation and a direct calculation of the relevant correlation functions. In addition, we investigate multi-particle scattering states in the same system.

3:18PM T17.00005 Electrostatic modulation of periodic potentials in a two-dimensional electron gas: from antidot lattice to quantum dot lattice

, SRIJIT GOSWAMI, MOHAMMAD ALI AAMIR, SAQUIB SHAMIM, Department of Physics, Indian Institute of Science, CHRISTOPH SIEGERT, Cavendish Laboratory, University of Cambridge, MICHAEL PEPPER, Department of Electronic and Electrical Engineering, University College London, IAN FARRER, DAVID RITCHIE, Cavendish Laboratory, University of Cambridge, ARINDAM GHOSH, Department of Physics, Indian Institute of Science — We use a dual gated device structure to introduce a gate-tunable periodic potential in a GaAs/AlGaAs two dimensional electron gas (2DEG). Using a suitable choice of gate voltages we can controllably alter the potential landscape in the 2DEG, thereby inducing either a periodic array of antidots or quantum dots. Antidots are artificial scattering centers, and therefore allow for a study of electron dynamics. On the other hand, a quantum dot lattice provides the opportunity to study correlated electron physics. We use a variety of electrical measurements such as magneto-resistance, thermo-voltage and current-voltage characteristics to probe these two contrasting regimes.

3:30PM T17.00006 Universal out-of-equilibrium transport in Kondo-correlated quantum dots: a renormalized superperturbation theory on the Keldysh contour, STEFAN KIRCHNER, Max Planck Institute for Physics of Complex Systems, Germany, ENRIQUE MUNOZ, Pontificia Universidad Catolica de Valparaiso, Chile, C.J. BOLECH, University of Cincinnati — The non-linear conductance of semiconductor heterostructures and single molecule devices exhibiting Kondo physics has recently attracted attention [1,2]. We address the observed sample-dependence across various systems by considering additional electronic contributions present in the effective low-energy model underlying these experiments. To this end we develop a novel version of the superperturbation theory [3] in terms of dual fermions on the Keldysh contour. We analyze the role of particle hole asymmetry on the transport coefficients. Our approach [4] systematically extends the work of Yamada and Yosida and others to the particle-hole asymmetric Anderson model and reproduce the exactly solvable resonant level model and the special case considered in [5]. It correctly describes the strong coupling physics and is free of internal inconsistencies that would lead to a breakdown of current conservation.

3:42PM T17.00007 Multi-state operation in quantum dot channel FETs incorporating spatial wavefunction-switching¹, F. JAIN, K. BASKAR, S. KARMAKAR, P-Y. CHAN, E. SUAREZ, B. MILLER, J. CHANDY, University of Connecticut, E. HELLER, RSoft Design Group — Three-state behavior has been demonstrated in Si and InGaAs quantum dot gate (QDG) field-effect transistors^{2,3} (FETs). Recently, spatial wavefunction switched⁴ (SWS) and quantum dot channel⁵ (QDC) FETs have been reported to exhibit four-state operation. This paper presents simulations of versatile combinations of SWS features in QDC channels to optimally design multi-state transport in FETs that have the potential of scaling to sub-12nm regime. A QDC-FET channel is modeled as having superlattice-like mini-energy bands where the carrier wavefunctions are transferred across the channel as drain voltage is changed, producing step-like multi-state electrical characteristics. This behavior is analogous to that of single electron transistors.⁶ The difference is that QDC devices use more than a few electrons and operate at room temperature. The SWS feature additionally provides carrier transfer from lower to upper dot layer(s) in a QDC having more than one layer of quantum dots.

3:54PM T17.00008 Tunneling in double quantum dots and rings: search for chaos assistance¹, IGOR FILIKHIN, SERGEI MATINYAN, BRANISLAV VLAHOVIC, North Carolina Central University — Semiconductor heterostructures as quantum dots (QD) or quantum rings (QR) demonstrate discreet atom-like energy level structure. In the case of double QD (DQD) or double concentric QR (DCQR), a single electron spectrum is composed of a set of quasi-doublets [1]. We study influence of these specific spectrum properties on electron tunneling related to the electron transport through DQD (DCQR). The double InAs/GaAs quantum dots (rings) are considered within three dimensional single sub-band effective approach [2]. Tunneling between dots (rings) is evaluated by effect of inter-dot distance and QD (QR) geometry. We show that the quasi-doublets of the electron spectra define tunneling properties of the DCQR. Violation of symmetry of the DCQR geometry leads to increase of tunneling. Discussed will be also the chaos assisted tunneling in the double QD (DCQR).

4:06PM T17.00009 First-principles study of orbital-dependent quantum confinement in Si/Ge nanowire superlattices, MIN-KOOK KIM, HYOUNG JOON CHOI, Yonsei University — We study electronic structures of H-passivated Si/Ge nanowire superlattices (NWSLs) oriented along [110] direction, using an *ab-initio* pseudopotential density-functional method with the local density approximation. Obtained electronic structures of the Si/Ge NWSLs show both dispersive and non-dispersive bands in conduction and valence bands due to band-selective quantum confinement: the highest valence band and the lowest conduction band are not confined in either the Si- or Ge-nanowire segment but they are extended throughout the whole NWSLs, while there exist non-dispersive bands confined in either Si- or Ge-nanowire segment below the top of the valence band and above the bottom of the conduction band. This feature originates from strong orbital-dependence of quantum confinement of electronic states, making conventional band-offset diagrams for superlattices invalid in Si/Ge NWSLs. Effects of atomic geometries on the confinement are studied with different diameters and superlattice periodicities. This work was supported by NRF of Korea (Grant Nos. 2009-0081204 and 2011-0018306). Computational resources have been provided by KISTI Supercomputing Center (Project No. KSC-2011-C3-05).

4:18PM T17.00010 One-dimensional physics in transition-metal nanowires¹, JUNICHI OKAMOTO, ANDREW MILLIS, NADER ZAKI, CHRIS MARIANETTI, Columbia University — One atom wide transition-metal nanowires can now be fabricated on Cu step edges. We present a theoretical study of the electronic properties of such systems. While the systems fall within the broad class of Luttinger liquids, about which much is known, characteristic features of transition metals including orbital degeneracy and interactions which favor locally high-spin configurations lead to new physics. Density functional calculations indicate that Co nanowires on Cu surfaces are half metals and are not electronically isolated from the substrate material. The multi-orbital and local high-spin physics are elucidated by Hartree-Fock approximations and bosonization calculations of the multi-orbital Hubbard model.

4:30PM T17.00011 Detection of spin states in a quantum dot by random telegraph signal analysis with the hidden Markov model, MATTHEW HOUSE, HONGWEN JIANG, University of California, Los Angeles, MING XIAO, GUOPING GUO, HAIYOU LI, GANG CAO, TAO TU, GUANGCAN GUO, Key Laboratory of Quantum Information, Chinese Academy of Sciences, University of Science and Technology of China — A lateral GaAs quantum dot with an adjacent quantum point contact charge sensor was tuned so that its chemical potential is close to the Fermi level of an adjacent electron reservoir. In this configuration electrons tunnel back and forth between the quantum dot and the reservoir due to thermal fluctuations, characteristic switching known as a random telegraph signal (RTS). The charge state of the quantum dot is directly observable, but spin and orbital state information is not. Such extra states may reveal themselves in the statistics of the timing of tunneling events. We present a statistical analysis approach based on the Hidden Markov Model (HMM) for extracting information about the internal structure of the quantum dot from RTS data, particularly focusing on determining the electronic spin state. We demonstrate on simulated and experimental data that this technique can detect electron spin states and measure their tunneling rates individually when the energy level difference is less than or comparable to the thermal energy scale. This opens a new regime for studying quantum dot spin physics because other experiments require a Zeeman energy difference greater than the thermal energy in order to distinguish the spin states.

4:42PM T17.00012 Impact of adsorbed organic monolayers on vacuum electron tunneling contributions to electrical resistance at an asperity contact, DIANA BERMAN, MATTHEW WALKER, JACQUELINE KRIM, North Carolina State University — Electrical Contact Resistance measurements are reported for RF MEMS switches situated within an ultrahigh vacuum system equipped with *in situ* oxygen plasma cleaning capabilities. Measurements were performed on Au/Au permanently adhered switches, and functioning Au/RuO₂ switches in the presence and absence of adsorbed monolayers of pentane and dodecane. The data are analyzed to explore how adsorbed molecules in regions close to the contact may impact vacuum tunneling contributions to the experimentally measured resistance: (1) The resistance associated with direct contact in parallel with a vacuum tunneling path, which upon uptake of the monolayer is replaced by the molecular resistance, and (2) A series connection of the direct contact resistance with the molecular layer after adsorption occurs, with the vacuum tunneling path assumed to be negligible. The results favor scenario (1), whereby uptake of the molecular layer effectively shuts down the vacuum tunneling path, which in this case is effectively ~30 Ohms in the absence of an adsorbed film. The methods constitute a new and original approach to documenting vacuum tunneling levels in regions of close proximity. Funding agencies: NSF, AFOSR MURI, DARPA.

4:54PM T17.00013 Dependence of Conductance Resonances and Modulations on Channel Length in Asymmetric Quantum Point Contacts (QPCs)¹, HAO ZHANG, Duke University, PHILLIP WU, Lund University, ALBERT CHANG, Duke University — Transport features below $2e^2/h$ show resonance peaks in highly asymmetric QPCs. As we increase the channel length, the number of peaks observable also increases. We characterize the number of peaks and/or oscillations as a function of channel length, when the QPC is tuned to or below the first quantum channel. The number of peaks/oscillations appears to increase on average as the channel length increases. In addition, we find preliminary evidence that there is a correspondence between the resonance peaks and the zero-bias anomaly (ZBA) in the differential conductance. These behaviors are consistent with an interpretation based on the formation of quasi-bound-states within the QPC channel in the single-mode limit.

5:06PM T17.00014 New scenario of shuttling mechanism in magnetic nano-electromechanical single-electron tunneling systems, HEE CHUL PARK, School of Computational Science, Korea Institute for Advanced Study, ANATOLI M. KADIGROBOV, ROBERT I. SHEKHTER, MATS JONSON, Department of Physics, University of Gothenburg — We investigate a new shuttling scenario in the electro-mechanics of a movable quantum dot between a nonmagnetic lead and a magnetic lead. In this device, the quantum dot has two energy levels due to the Zeeman energy splitting under magnetic field with Coulomb blockade. The electromechanical instability is shown to depend on the external voltage when the vibrating energy overcomes the dissipation energy of the system. In addition to the normal shuttling behavior, the shuttling current can be suppressed and then recovered depending on the external voltage. It is also found that the nano-electromechanical oscillation significantly improves the spin polarized current compared with one in the fixed quantum dot due to the interplay between the spin polarized transport and mechanical degree of freedom.

Session T18 DMP: Focus Session: Interfaces in Complex Oxides - Superconductivity and Magnetism at Interfaces 252B

2:30PM T18.00001 Local imaging of the superfluid density at the LAO/STO interface as a function of gate voltage, JULIE A. BERT, BEENA KALISKY, CHRIS BELL, YASUYUKI HIKITA, HAROLD Y. HWANG, KATHRYN A. MOLER, Stanford Institute for Materials and Energy Sciences, Stanford University — The interface between two insulating oxides, LaAlO₃ and SrTiO₃, exhibits a two-dimensional electron system with high mobility, magnetism, superconductivity at low temperatures, and an electric-field-tuned superconductor-insulator transition. This interface has been studied extensively using transport and magnetization, which do not directly probe potential variation on a local length scale. We use a scanning SQUID microscope to locally probe superconductivity and magnetism in LAO/STO heterostructures. We measure the local diamagnetic susceptibility and critical temperature as a function of position and gate voltage. Our local susceptibility measurement is related to the density of superconducting carriers which gives us a map of superfluid density. We find that the superfluid density is inhomogeneous, showing regions of susceptibility that varies over a large fraction of the total response while the critical temperature remains relatively uniform across the sample. Tracking the evolution of both of these parameters as a function of gate voltage and position enables investigation of the local onset of the superconductor-insulator transitions on both sides of the dome.

2:42PM T18.00002 Magnetism and superconductivity at LAO/STO-interfaces: the role of Ti 3d interface electrons¹, NATALIA PAVLENKO, Institute of Physics, University of Augsburg (Germany); Institute for Condensed Matter Physics, Lviv (Ukraine), THILO KOPP, Institute of Physics, University of Augsburg (Germany), E.Y. TSYMBAL, Department of Physics and Astronomy, University of Nebraska-Lincoln, G.A. SAWATZKY, Department of Physics and Astronomy, University of British Columbia, Vancouver, JOCHEN MANNHART, Max Planck Institute for Solid State Research, Stuttgart (Germany) — Ferromagnetism and superconductivity are in most cases adverse. However, recent experiments reveal that they coexist at interfaces of LaAlO_3 and SrTiO_3 [1]. We analyze the ferromagnetic state within density functional theory and provide evidence that it is also generated by Ti 3d interface electrons, as is the two-dimensional electron liquid at the interface which gives rise to superconductivity [2]. We demonstrate that oxygen vacancies in the TiO_2 interface layer enhance the tendency for ferromagnetism considerably. This allows for the notion that areas with increased density of oxygen vacancies produce ferromagnetic puddles and account for the previous observation of a superparamagnetic behavior in the superconducting state [3].

2:54PM T18.00003 Superconductivity and magnetism in the presence of interface-induced Rashba spin-orbit coupling¹, FLORIAN LODER, ARNO KAMPF, THILO KOPP, University of Augsburg, Germany, TRR 80 TEAM — Two dimensional electron systems at oxide interfaces are often influenced by a Rashba type spin-orbit coupling (SOC), which is tunable by a transverse electric field. Ferromagnetism at the interface can simultaneously induce strong local magnetic fields. This combination of SOC and magnetism leads to anisotropic two-sheeted Fermi surfaces, on which superconductivity with finite-momentum pairing is favored. The superconducting order parameter is derived within a generalized pairing model realizing both, the FFLO superconductor in the limit of vanishing SOC and a mixed-parity pairing state with zero pair momentum if the magnetism vanishes. The nature of the pairing state is discussed in the context of interface superconductivity and ferromagnetism at LAO-STO interfaces [1,2].

3:06PM T18.00004 Superconductivity and magnetism in a three-band model of the LAO/STO interface from a weak-coupling perspective, MARK FISCHER, Cornell University, SRINIVAS RAGHU, Stanford University, EUN-AH KIM, Cornell University — Recent experiments on LAO/STO interfaces have shown the occurrence of both superconductivity and magnetism in this system. Motivated by these experiments, we analyze various Fermi-liquid instabilities in a three-band model of the LAO/STO interface with purely repulsive interactions by calculating susceptibilities for superconducting, magnetic and nematic orders. In light of recent transport experiments proposing a Lifshitz transition between d orbitals, we particularly study how the susceptibilities depend on the chemical potential. Further, we investigate the interplay of these different orders.

3:18PM T18.00005 Magnetism of $\text{LaAlO}_3/\text{SrTiO}_3$ Heterostructure Interface, LU LI¹, Department of Physics, Massachusetts Institute of Technology, C. RICHTER, University of Augsburg, D-86135 Augsburg, Germany, J. MANNHART, Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany, R.C. ASHOORI, Department of Physics, Massachusetts Institute of Technology — The $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructure is a potential candidate for a high mobility two-dimensional electron system with novel electronic and magnetic properties. Magnetic ordering has been proposed to arise from d-shell electrons transferred by the polarization discontinuity at the interface. However the magnetization of this system cannot easily be detected with standard techniques due to the small volume of the interfacial region. Using torque magnetometry, we measure the magnetic moment of the interface system directly. Our results indicate the existence of a magnetic ordering at the two-dimensional conductive interface. The ferromagnetic-like ordering state persists up to 200 K. Such a state is hardly explained by ion-exchange at the interface, since LaTiO_3 is antiferromagnetic. Moreover, the same magnetic behavior persists even when the sample is superconducting, which suggests an unconventional two-dimensional superconducting phase.

3:30PM T18.00006 Signatures of local superconducting islands at elevated temperatures in $\text{LaAlO}_3/\text{SrTiO}_3$ Heterostructure Interface, R.C. ASHOORI, LU LI¹, Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02138, C. RICHTER, University of Augsburg, D-86135 Augsburg, Germany, J. MANNHART, Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — Superconductivity has been observed in $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures below 300 mK in resistivity measurements and later confirmed with Meissner effect. Our detailed magnetization measurements in several $\text{LaAlO}_3/\text{SrTiO}_3$ samples indicate a quasi superconducting state persisting up to 4 K. In these samples, we discovered large nonreversible magnetization vs. field curves. Moreover, the magnitude of the nonreversible loop is proportional to sweep rates, suggesting that it is caused by local magnetic moments generated by eddy currents. Based on this eddy current picture, the inferred conductance is found to be 7 orders of magnitude larger than the conductance across the whole interface. This contrast suggests the existence of small local quasi superconducting regions at a temperature of 4 K, well above the long range superconducting transition temperature.

3:42PM T18.00007 Superconductivity and Ferromagnetism in Oxide Interface Structures: Possibility of Finite Momentum Pairing, KAREN MICHAELI, ANDREW POTTER, PATRICK LEE, Massachusetts Institute of Technology — We present a model that captures the physical properties of the interface between two oxides, LaAlO_3 and SrTiO_3 . Despite extensive experimental studies of these systems, no clear theoretical picture has emerged so far. The model that we suggest for the interface electrons explains the main experimental observations. In particular, we address one of the most intriguing phenomena observed in these system: the coexistence of ferromagnetism and superconductivity. Ordinarily this ferromagnetism would destroy superconductivity, but due to strong spin-orbit coupling near the interface, the magnetism and superconductivity can coexist by forming an FFLO-type condensate of Cooper pairs at finite momentum. Surprisingly, this unconventional superconducting state survives even at strong disorder.

3:54PM T18.00008 Tuning the ferromagnetism in $\text{LaAlO}_3/\text{SrTiO}_3$, BEENA KALISKY, Stanford University, USA; Bar-Ilan University, Israel, JULIE A. BERT, BRANNON B. KLOPPER, CHRISTOPHER BELL, Stanford University, USA, HIROKI SATO, Stanford University, USA; University of Tokyo, Japan, YASUYUKI HIKITA, HAROLD Y. HWANG, KATHRYN A. MOLER, Stanford University, USA — The interface of $\text{LaAlO}_3/\text{SrTiO}_3$ heterostructures exhibits both conductivity and magnetism. Significant effort has been invested researching the details and characteristics of the conductivity, such as conductance only above a critical LaAlO_3 thickness. However, reports of ferromagnetism differ in a variety of details requiring further investigation into the material properties that control magnetism. In this study we use a scanning SQUID microscope to locally image the landscape of ferromagnetism as a function of several tuning parameters including the LaAlO_3 thickness, back gate voltage, local strain and surface treatment. We find that the ferromagnetism is inhomogeneous within each sample, varies considerably between samples, and appears only in samples whose LaAlO_3 layer is thicker than a threshold value, similar to the conductance critical thickness. The ferromagnetism changes with local strain, surface treatment with polar solvents and applied field. However it is not affected by changing the gate voltage or cycling the temperature up to 300K. These results provide experimental input for determining and controlling the mechanisms of magnetism in engineered complex oxide interfaces.

4:06PM T18.00009 Strong magnetic interaction in localized two-dimensional electron gas in $\text{LaAlO}_3/\text{SrTiO}_3/\text{NdGaO}_3$ heterostructures¹ , Z. HUANG, X. WANG, Z.Q. LIU, W.M. LV, S.W. ZENG, A. ANNADI, W.L. TAN, T. VENKATESAN, - ARIANDO, NUSNNI-NanoCore, National University of Singapore, Singapore — Via reducing the thickness of SrTiO_3 layer, strong localization of two-dimensional electron gas is artificially introduced at $\text{LaAlO}_3/\text{SrTiO}_3$ interface grown on NdGaO_3 (110) substrates. This localization is characterized by the low carrier density, robust insulating ground state and variable range hopping behavior at low temperature. Given the spatially-limited conducting channel in the thin SrTiO_3 layer, the degeneration of Ti 3d orbitals at the interface should be responsible for this strong localization. Moreover, the typical butterfly-like hysteresis loop and unusual anisotropic features in magnetoresistance observed in the thinner SrTiO_3 samples indicate the enhanced magnetic interaction in this strongly localized two-dimensional electron gas.

4:18PM T18.00010 Investigation of electric field induction of superconductivity at complex oxide interfaces¹ , J.T. HARALDSEN, Los Alamos National Laboratory, P. WOLFLE, Karlsruhe Institute of Technology, A.V. BALATSKY, Los Alamos National Laboratory — We examine the modified electronic states and change in carrier density at the interfaces of complex oxide films produced by an external electric field. Using a Ginzburg-Landau formalism and ab-initio calculations, we show that linear coupling of an electric potential can influence the superconducting order parameter and induce a transition to a superconducting phase. Further, we examine the correlation between carrier density and the superconducting critical temperature T_c by investigating capacitance and density of states with changing electric potential. We will discuss implications of this work in the context of interfaces formed by LaAlO_3 and SrTiO_3 thin films. This approach points to an alternative path to superconducting devices with tunable transition temperature. Work was carried out under the help and support of the National Nuclear Security Administration of the U.S. Department of Energy at Los Alamos National Laboratory under Contract No. DE-AC52-06NA25396.

4:30PM T18.00011 Evidence for charge-vortex duality at the $\text{LaAlO}_3\text{-SrTiO}_3$ interface¹ , MANAN MEHTA, DIMITRY DIKIN, Department of Physics and Astronomy, Northwestern University, Evanston, IL, CHUNG WUNG BARK, CHAD FOLKMAN, CHANG-BEOM EOM, Department of Materials Science and Engineering, University of Wisconsin-Madison, Madison, WI, VENKAT CHANDRASEKHAR, Department of Physics and Astronomy, Northwestern University, Evanston, IL — The conducting gas formed at the interface between LaAlO_3 and SrTiO_3 undergoes a superconductor to insulator transition (SIT) on the application of a back gate voltage, V_g . The system also shows evidence of ferromagnetic order coexisting with superconductivity.² The juxtaposition of the ferromagnet with the conducting gas allows for the observation of a novel manifestation of charge-vortex duality. The field due to the magnetization dynamics in the ferromagnet causes a sharp *increase* in resistance on the superconducting side of the transition, in the magnetoresistance measurements, and a sharp *decrease* in resistance on the insulating side. The system can be modeled as an array of Josephson junctions, with two characteristic energy scales: a Josephson coupling energy E_J , and a Coulomb charging energy E_C . V_g then tunes the ratio, E_J/E_C , to cause the transition. We will present external field sweep-rate dependent magnetoresistance data on both sides of the transition to elucidate the nature of the superconducting and insulating states.

²Dikin *et al*, PRL **107**, 056802 (2011)

4:42PM T18.00012 Single-Mode Cooper Pair Channel in $\text{LaAlO}_3/\text{SrTiO}_3$ Nanowires , JOSHUA VEAZEY, GUANGLEI CHENG, PATRICK IRVIN, MENGCHEN HUANG, U. of Pittsburgh, CHUNG WUNG BARK, SANGWOO RYU, CHANG-BEOM EOM, U. of Wisconsin-Madison, JEREMY LEVY, U. of Pittsburgh — The conducting $\text{LaAlO}_3/\text{SrTiO}_3$ interface becomes superconducting¹ below a critical temperature $T_c \sim 100\text{-}400$ mK. Here, we investigate the transport characteristics of $\text{LaAlO}_3/\text{SrTiO}_3$ structures formed from ~ 10 nm-wide nanowire segments produced by a conductive atomic force microscope lithography technique². Above $T_c \sim 200$ mK we find a characteristic four-terminal conductance $G \sim e^2/h$ that is independent of the channel length. Below T_c we find that the conductance increases to $G \sim 4e^2/h$. This increase is attributed to the formation of Cooper pairs that propagate in a single mode. We also discuss the interactions between Cooper pairs and spin-polarized transport in these structures. This work is supported by AFOSR (FA9550-10-1-0524).

4:54PM T18.00013 Two doped holes with different distributions in $\text{Sr}_2\text{CuO}_{4-\delta} - \text{La}_2\text{CuO}_4$ superlattices¹, S. SMADICI, J.C.T. LEE, P. ABBAMONTE, University of Illinois at Urbana-Champaign, IL 61801, USA, A. RUSYDI, National University of Singapore, 11754, Singapore, G. LOGVENOV, Max-Planck-Institut for Solid State Research, D-70569, Germany, I. BOZOVIC, Brookhaven National Laboratory, NY 11973, USA — X-ray absorption in $\text{Sr}_2\text{CuO}_{4-\delta} - \text{La}_2\text{CuO}_4$ (SCO-LCO) superlattices shows a variable occupation with doping of two hole states. In addition to the holes doped for $x < x_{\text{optimal}}$ in bulk $\text{La}_{2-x}\text{Sr}_x\text{CuO}_4$, a variation with doping of a second hole state is observed at higher energy. Measurements suggest that this hole is located on apical oxygen atoms and polarized in the $a - b$ plane. Considering the surface reflectivity gives a good qualitative description of the line shapes of resonant soft X-ray scattering. The interference between the superlattice and surface reflections was used to distinguish between scatterers in the SCO and the LCO layers, with the two hole states maximized in different layers of the superlattice. This suggests that the states emptied preferentially in the SCO layers are the additional states in the extension of the Zhang-Rice singlet-upper Hubbard band model to higher doping levels.

5:06PM T18.00014 Highly Spin-Polarized Conducting State at the Interface between Non-magnetic Band Insulators: $\text{LaAlO}_3/\text{FeS}_2$ (001), J.D. BURTON, E.Y. TSYMBAL, University of Nebraska - Lincoln, Nebraska Center for Materials and Nanoscience — Interface engineering of complex oxide heterostructures allows creating interfaces with properties and functionalities distinct from those typical for the respective bulk constituents. In the spirit of the well known conducting $\text{LaAlO}_3/\text{SrTiO}_3$ interface we study a similar interface with the added functionality of being unambiguously ferromagnetic. Our first-principles density functional calculations demonstrate that such a spin-polarized two-dimensional conducting state can be realized at the (001) interface between the two non-magnetic band insulators FeS_2 and LaAlO_3 . The (001) surface of FeS_2 (pyrite), a diamagnetic insulator, supports a localized surface state deriving from the Fe d-orbitals near the conduction band minimum. We find that, similar to the $\text{LaAlO}_3/\text{SrTiO}_3$ system, the deposition of a few unit cells of the polar perovskite oxide LaAlO_3 leads to electron transfer into these surface bands, thereby creating a conducting interface. The occupation of these narrow bands leads to an exchange splitting between the spin sub-bands, yielding a highly spin-polarized conducting state quite distinct from the rest of the non-magnetic, insulating bulk. Session T19 APS: Kavli Foundation Special Session: Emergent Physics at the Mesoscale Ballroom East

2:30PM T19.00001 Mesoscopic Lawlessness, R.B. LAUGHLIN, Stanford University — Whether physics will contribute significantly to unraveling the secrets of life, the grandest challenge of them all, depends critically on whether proteins and other mesoscale objects exhibit emergent law. By this I mean quantitative relationships among their measured properties that are always true. The jury is still out on the matter, for there is evidence both for and against, but it is spotty, on account of the difficulty of measuring 100 nm - 1000 objects without damaging them quantum mechanically. It is therefore not clear that history will repeat itself. Physics contributed mightily to 20th century materials science through its identification and mastery of powerful macroscopic emergent laws such as crystalline rigidity, superconductivity and ferromagnetism, but it cannot do the same thing in biology, regardless of how powerful computers get, unless nature cooperates. The challenge before us as physicists is therefore not to amass more and more terabytes of data and computational output but rather to search for and, with luck, find operating principles at the scale of life greater than those of chemistry, which is to say, greater than a world ruled by nothing but miraculous accidents.

3:06PM T19.00002 Ultracold, trapped atomic gases as material systems¹, WILLIAM D. PHILLIPS², Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology, 100 Bureau Drive, Stop 8424, Gaithersburg MD 20899 — Laser cooling and evaporative cooling of neutral atomic gases has led to the creation of quantum degenerate Bose and Fermi gases that constitute a new class of material systems. Many of the features of the Hamiltonians governing the behavior of these systems can be controlled and manipulated in experiments. The necessarily finite sizes of such systems are often mesoscopic in the sense that they are large enough that collective effects are important, yet small enough that the size plays a role in determining the systems' behavior. Among the experimental tools available are optical lattices, synthetic fields, and the ability to change the size and dimensionality of the system. Ultracold gases can realize some of the idealized Hamiltonians used to model condensed matter systems, creating a quantum simulation of such models, which may be computationally intractable. Atomic gases can also provide new condensed-matter-like systems that have no analogs in real condensed matter.

Session T20 FIAP: Invited Session: Advanced Characterization of Transistor Gate Stacks and Interfaces 253C

2:30PM T20.00001 Directions in High-k Gate Stacks: From Silicon Chips to Carbon Nano-materials, MATTHEW COPEL, IBM — The successful implementation of high-k/metal gates for silicon CMOS has culminated a decade of research on metal-oxide interactions with silicon. The ability to profile materials on a nanometer length scale has greatly assisted our ability to tailor electrical properties to create functional devices. Initial concerns addressed with composition profiling (e.g. Si content, Hf diffusion, thermal stability) have been replaced by more advanced questions. For example, gate-first technologies often use threshold-modifying layers, whose electrical properties are closely linked with their depth distribution. Oxygen diffusion is another complex problem of current concern, where physical characterization by isotopic tracing has given valuable insights. A similar set of challenges will confront us in creating carbon-based devices. Much effort is focused on nucleation of dielectrics, along with stability and interactions with the channel. This parallels work in the early development of high-k/Si. This talk will review some important lessons from the past decade, and discuss how we can apply this knowledge to creating improved graphene-channel devices.

3:06PM T20.00002 Nanometer-scale properties of metal/oxide interfaces and “end-on” metal contacts to Si nanowires studied by ballistic electron emission microscopy (BEEM)¹, JON PELZ, The Ohio State University, Dept. of Physics, Columbus, OH 43210 — BEEM is a hot-electron (HE) technique based on scanning tunneling microscopy that can probe buried metal/semiconductor and metal/dielectric interfaces with nm-scale spatial resolution and energy resolution of a few meV. BEEM is a three-terminal technique, so the HE energy and interface electric field can be varied independently. I will discuss two studies of interest for future transistor technologies. The first concerns the band structure and alignments in a 20 nm-thick film of the high-k dielectric material Sc_2O_3 grown epitaxially on Si(111). Sc_2O_3 and related rare-earth/transition metal oxide films on Si were found to have similar band alignments and bandgap, and also “tailing” conduction band (CB) states extending ~ 1 eV below the primary CB. We combined BEEM with internal photoemission to measure the band alignment and to study electron transport through these “tail” states.² Surprisingly, these tail states were found to form a robust band of extended states that supports elastic hot-electron transport even *against* an applied electric field. The second study concerns HE injection and transport through “end-on” metal contacts made to ~ 100 nm diameter vertical Si nanowires (NWs) embedded in a SiO_2 dielectric. At low HE flux, We observed *lateral variations* of the local Schottky Barrier Height (SBH) across individual end-on Au Schottky contacts, with the SBH at the contact edge found to be ~ 25 meV lower than at the contact center. Finite-element electrostatic simulations suggest that this is due to a larger interface electric field at the contact edge due to positively charged Si/native-oxide interface states near the Au/NW contact, with this (equilibrium) interface state charge induced by local band bending due to the high work function Au contact. We also observed a strong *suppression* of the hot-electron transmission efficiency at larger HE flux, likely due to (non-equilibrium) *steady-state negative charge accumulation* in metastable traps at the Si/oxide interface located near the injecting metal contact. Ongoing BEEM measurements of metal contacts to SrTiO_3 substrates and films may also be discussed.

3:42PM T20.00003 Metropolis Prize Talk: Defects in Al_2O_3 and their impact on III-V/ Al_2O_3 MOS-based devices, JUSTIN R. WEBER, Intel Corporation, Hillsboro, OR — As the dimensions of conventional silicon devices continue to shrink, novel approaches are required to achieve increasing performance demands. Recently Intel announced the implementation of a 3-D MOSFET geometry known as the tri-gate transistor for their 22 nm technology. In addition to different geometries, new materials will also be needed for future technologies. In this talk, we will consider the use of III-V channel materials, and novel gate dielectrics. Al_2O_3 is a promising dielectric for III-V devices. However, the presence of deep levels and fixed charge in the Al_2O_3 layer is a concern, with native defects being a potential source of traps, leakage, and fixed charge. We will present the results of hybrid density functional calculations for such defects. The energetic positions of defect-induced levels will be discussed in the context of the III-V/ Al_2O_3 interface. We find that native defects are a source of border traps, and fixed charge in the dielectric. We will also discuss the interaction of hydrogen with such defects, in the context of passivation. Our results indicate that hydrogen is effective at removing border traps, and helps to alleviate the problem of fixed charge. This work was performed in collaboration with A. Janotti and C. G. Van de Walle.

4:18PM T20.00004 Charge Traps at and near High-K Oxide/III-V Interfaces¹, PAUL MCINTYRE, Stanford University — The effort to achieve higher performance metal-oxide-semiconductor (MOS) devices prompts interest in new semiconductor channel materials such as indium gallium arsenide that can achieve larger drive currents than state-of-the-art Si field effect transistors, at low operating voltages. In order for InGaAs-channel transistors to approach their performance limits, however, high permittivity (high-k) metal oxide gate dielectrics must be prepared on the III-V surface in a manner that produces a minimal areal density of charge-trapping defects. This presentation will review different experimental approaches to prepare relatively passive interfaces between deposited oxides and GaAs or InGaAs. Both pre-oxide deposition and post-deposition methods will be summarized. It will also describe the influence of near-interface defects in the oxides (border traps) and why these particular defects are so significant for arsenide MOS devices. An attempt will be made to associate electrically-active traps detected at different energies in the III-V semiconductor bandgap with specific surface and point defects, based on prior reported experimental and computational observations. The difficulty of quantifying trap densities using typical capacitance-voltage and conductance-voltage methods developed for silicon MOS will be discussed.

¹Support by the SRC Non-Classical CMOS Center is gratefully acknowledged.

4:54PM T20.00005 Electrical characterization of interfacial defects, GENNADI BERSUKER, SEMATECH — Aggressive transistor scaling to achieve better chip functionality calls for the introduction of new dielectric and metal materials into traditional device gate stacks. The advanced gate stacks represent multilayer structures, the materials of which may strongly interact (primarily during high temperature processing), generating structural defects in these layers. These complex structures pose new challenges in interpreting electrical measurements, which are sensitive to even extremely small concentrations of electrically active defects. The critical task is, thus, to link the structural and electrical characteristics of these multicomponent gate stacks in order to identify and control defects affecting device performance. In this presentation, we focus on analyzing interfacial defects affecting electrical characteristics of the metal/high-k (HK) gate stacks, which are of major interest to the semiconductor industry. We first developed models of the physical processes governing the measurements of the electrical techniques we used that allowed us to extract the structural parameters of the defects from the electrical data. By comparing the extracted parameters to those obtained by ab initio calculations of the material structures, we identified the nature of the contributing defects. A recently proposed model for random telegraph noise (RTN) and frequency-dependent charge pumping (CP) measurements that takes into consideration the multi-phonon lattice relaxation induced by charge trapping/detrapping at the defect sites was employed to extract characteristics of the traps in the interfacial SiO_2 layer in HfO_2 -based HK devices. Our results indicate that the electron capture/emission times are controlled by the lattice re-arrangement (caused by the trapped electrons) rather than by electron tunneling to/from the trap as generally assumed. The strong dependency of the measured values on defect relaxation and ionization energies allows these values to be extracted; the values can then be used as a defect identifier. Complementary modeling of the gate leakage current in HK devices during electrical stress using the same approach yields characteristics of the traps in the interfacial SiO_2 layer contributing to trap-assisted tunneling (TAT). Based on the values obtained by RTN, CP, and TAT measurements, the electrically active defects were tentatively assigned to oxygen vacancies in various charged states. In all cases, stress-induced traps were generated exclusively in the interfacial layer of the HK stacks, consistent with earlier findings that HK dielectrics are more resistant to defect generation than SiO_2 . Based on these findings, as well as an earlier TEM/EELS study of the elemental composition of the breakdown path, we proposed that the breakdown path formation/evolution in the interfacial layer is associated with the growth of an oxygen-deficient filament facilitated by the grain boundaries in the overlaying high-k film. This model successfully describes the temperature-dependent evolution of interfacial layer degradation through various breakdown phases.

Wednesday, February 29, 2012 2:30PM - 5:30PM – Session T21 DCMP: Magnetic Ordering and Dynamics in Cuprates 254A

2:30PM T21.00001 Two Dimensional Incommensurate and Three Dimensional Commensurate Magnetic Order and Fluctuations in $La_{2-x}Ba_xCuO_4$ ¹, JEROD WAGMAN, GREG VAN GASTEL, KATE ROSS, McMaster University, ZAHRA YAMANI, Chalk River Laboratories, YANG ZHAO, National Institute of Standards and Technology, ANN KALLIN, EMMA MAZUREK, Brockhouse Institute for Materials Research, YIMING QIU, JOHN COPLEY, National Institute of Standards and Technology, HANNA DABKOWSKA, Brockhouse Institute for Materials Research, BRUCE GAULIN, McMaster University — We present neutron scattering measurements on single crystals of $La_{2-x}Ba_xCuO_4$, with $0 \leq x \leq 0.035$. These experiments reveal the evolution of the magnetism: from a three dimensional (3D) commensurate (C) antiferromagnet, with a relatively high T_N , to a two dimensional (2D) incommensurate (IC) antiferromagnet with finite range static correlations, with relatively low effective T_N s. At low temperatures, the 2D IC magnetism co-exists with the 3D C magnetism for Ba concentrations as low as $x = 0.0125$. We find that 3D C magnetism disappears by $x = 0.025$; consistent with the limit of $x \sim 0.02$ observed in the sister family of doped Mott insulators $La_{2-x}Sr_xCuO_4$. We construct a phase diagram based on magnetic order parameter measurements, which displays much of the complexity of standard high temperature superconductivity phase diagrams discussed in the literature. Analysis of high energy-resolution inelastic neutron scattering shows the low energy dynamic susceptibility to fall off with temperature on a scale much higher than the effective 2D IC T_N s in the sample. This effect is such that appreciable dynamic 2D IC magnetic fluctuations inhabit much of the “pseudogap” regime of the phase diagram.

2:42PM T21.00002 ABSTRACT WITHDRAWN —

2:54PM T21.00003 Novel magnetic excitations in the high-temperature superconductor $HgBa_2CuO_{4+\delta}$, MUN CHAN, University of Minnesota, YUAN LI, Max Planck Institute for Solid State Research, Germany, V. BALÉDENT, Laboratoire Léon Brillouin, N. BARIŠIĆ, University of Minnesota, K. HRADIL, Forschungsneutronenquelle Heinz Maier-Leibnitz, Germany, YANGMU LI, University of Minnesota, R.A. MOLE, Forschungsneutronenquelle Heinz Maier-Leibnitz, Germany, Y. SIDIS, Laboratoire Léon Brillouin, P. STEFFENS, Institut Laue Langevin, France, G. YU, University of Minnesota, X. ZHAO, Jilin University, China, P. BOURGES, Laboratoire Léon Brillouin, M. GREVEN, University of Minnesota — We report on the observation of novel magnetic excitations in the pseudogap phase of the cuprate superconductor $HgBa_2CuO_{4+\delta}$ ($Hg1201$) using neutron scattering, and on their relationship with antiferromagnetic (AF) fluctuations. Following polarized neutron diffraction experiments that demonstrated a novel ($q=0$) magnetic order in the pseudogap phase [B. Fauqué *et al.* PRL 96, 197001 (2006); Y. Li *et al.*, Nature 455, 372 (2008)], our inelastic measurements revealed two weakly-dispersive magnetic excitation branches in $Hg1201$ [Y. Li *et al.*, Nature 468, 283 (2010), and preprint]. These excitations are observed in the pseudogap phase and appear to be associated with the $q=0$ magnetic order. In our optimally-doped sample, the magnetic resonance occurs at the dispersion maximum of the higher-energy branch. In under-doped $Hg1201$, the two excitation branches exhibit local intensity maxima at q_{AF} , and we find evidence for an hourglass dispersion associated with the lower branch. These results reveal a profound connection between the novel excitations and the conventional AF fluctuations.

3:06PM T21.00004 Stripe order in $La_{2-x}Ba_xCuO_4$ in high magnetic fields¹, M. HUECKER, BNL, M. VON ZIMMERMANN, HASYLAB at DESY, Z.J. XU, J.S. WEN, G.D. GU, I.A. ZALIZNYAK, BNL, J.-H. CHUNG, NCNR at NIST, E.S. CHOI, NHMFL, J.M. TRANQUADA, BNL — The observation of enhanced spin stripe order in the vortex cores of $La_{2-x}Sr_xCuO_4$ has been a landmark experiment that revealed the intimate connection between superconductivity and incommensurate antiferromagnetism. Only recently we have observed a corresponding field dependence of the spin and, more importantly, of the charge stripe order in $La_{2-x}Ba_xCuO_4$. Here we present our recent results from neutron diffraction, x-ray diffraction, and torque measurements in high magnetic fields. These helped us to establish the field versus temperature and doping phase diagrams for spin and charge order, and to further corroborate the stripe model as the more appropriate description than for example spiral and vortex states.

¹Work at Brookhaven was supported by the Office of Science, U.S. Department of Energy.

3:18PM T21.00005 Pressure study of local tilts and their correlation to stripe order in single crystal $La_{1.875}Ba_{0.125}CuO_4$, GILBERTO FABBRIS, Argonne National Laboratory and Washington University in St. Louis, MARKUS HÜCKER, GENDA GU, JOHN TRANQUADA, Brookhaven National Laboratory, DANIEL HASKEL, Argonne National Laboratory — The strong T_c suppression in $LaBaCuO$ at $x=0.125$ is widely believed to be related to formation of static stripes, at least partially driven by a strong electron-lattice coupling in a low temperature tetragonal (LTT) phase (Tranquada *et al.*, Nature 375, 561 (1995)). A recent high-pressure experiment appears to challenge this view as it was observed that static stripe order persists to pressures higher than required to induce LTT to HTT transition (Hucker *et al.*, PRL 104, 057004 (2010)). We carried out high-pressure La K-edge polarized XAFS measurements in $LaBaCuO$ ($x=0.125$) single crystals in a diamond anvil cell to probe local CuO_6 tilts. We observe that the local tilts remain LTT-like at high pressure, even though the macroscopic structure is HTT. The results suggest a significant order-disorder component to this pressure-induced phase transition, whereby the local LTT tilts remain present in the local scale but disorder over long range resulting in HTT symmetry seen by diffraction. The result may help explain why the stripe order is largely unaffected by the LTT to HTT pressure-induced transition. Work at Argonne (BNL) is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357 (DE-AC02-98CH10886).

3:30PM T21.00006 Gutzwiller Charge and Magnetic Phase Diagrams of Cuprates¹, ROBERT MARKIEWICZ, Northeastern University, JOSE LORENZANA, Sapienza, University of Rome, GOETZ SEIBOLD, University of Cottbus, Germany, ARUN BANSIL, Northeastern University — We extend our previous analysis of the magnetic phase diagram of the cuprates to look for charge instabilities, either purely electronic or involving electron-phonon coupling, employing Gutzwiller approximation $GA+RPA$ calculations of the Hubbard model. In the absence of phonons we find an overscreening instability for large doping at (π, π) . In the presence of electron-phonon coupling, we find a rich response to Fermi surface nesting, very similar to the magnetic case, and in this case the instability criterion can be formulated as a generalized Stoner criterion. In the hole-doping regime, where evidence exists for a nonmagnetic (stripe) pseudogap, we find competing instabilities. Since the same susceptibility peaks are present for both spin and charge excitations, differences in preferred q -vectors arise from the q -dependence of the interaction $U_{eff,q}$.

¹Supported in part by the US DOE.

3:42PM T21.00007 The impact of incommensurate bond centered density waves in underdoped cuprates, LIANG NIESTEMSKI, Colgate University, ZIQIANG WANG, Boston College — We study the particle-particle channel and the particle-hole channel of the valence bond fluctuations away from half filling in cuprates. Based on strong-coupling analysis of the t-J model, we argue that the superexchange interaction J induced incommensurate bond centered density wave order is the driving mechanism for the pseudogap state. We show that the interplay between the incommensurate bond centered density wave instability and the intrinsic electronic inhomogeneity in real cuprates materials is responsible for the observed pseudogap phenomena.

3:54PM T21.00008 Two-component electron fluid and pseudogap asymmetry in underdoped high-Tc cuprate superconductors, JAMES STOREY, Victoria University of Wellington, New Zealand, JEFFERY TALLON, Industrial Research Ltd., New Zealand, GRANT WILLIAMS, Victoria University of Wellington, New Zealand — Evidence from NMR of a two-component spin system in the cuprate high-Tc superconductors is shown to be paralleled by similar evidence from the total electronic entropy so that a two-component quasiparticle fluid is implicated. We propose that this two-component behavior arises from reconstruction of the energy-momentum dispersion into two branches in the pseudogap regime. If correct then it follows that single-component electronic behavior will be recovered when the pseudogap closes in the overdoped regime. We illustrate this by calculating the spin susceptibility using the resonating valence bond spin liquid model developed by Yang, Rice and Zhang, finding excellent agreement with the NMR results. In addition, we find that the particle-hole asymmetric pseudogap of this model accounts for both the large thermoelectric power, and the downturn in resistivity observed in underdoped cuprates.

4:06PM T21.00009 Spin excitations in a layered antiferromagnetic metal, WENYA ROWE, Department of Physics, University of Florida, Gainesville, FL, JOHANNES KNOLLE, Max-Planck-Institut für Physik komplexer System, D-01187 Dresden, Germany, ILYA EREMIN, Institute für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL — The proximity of antiferromagnetic order in high-temperature superconducting materials is considered a possible clue to the electronic excitations which form superconducting pairs. Here we study the transverse and longitudinal spin excitation spectrum in a one-band model in the pure spin density wave (SDW) state and in the coexistence state of SDW and superconductivity. We start from a Stoner insulator which is similar to the case of cuprate parent compounds. By changing the chemical potential and the SDW order parameter, we study the evolution of the spectrum with different Fermi surfaces, such as the one with only hole pockets, with only electron pockets and with pockets of both types. We also compute the spin excitations in the coexistence of the AF and d-wave superconductivity, motivated by electron-doped cuprates.

4:18PM T21.00010 Coexistence of Superconductivity and Magnetic Order in $\text{RuGd}_2\text{Sr}(\text{Cu}_{1-x}\text{Fe}_x)_2\text{O}_8$ probed by ^{99}Ru and ^{57}Fe Mössbauer Effects¹, D. COFFEY, Dept. of Physics, Buffalo State College, NY, G. LONG, Dept. of Physics, SUNY Buffalo, M. DEMARCO, Dept. of Physics, Buffalo State College, NY, M. S. TORIKACHVILI, Dept. of Physics, San Diego State University — $\text{RuGd}_2\text{Sr}_2\text{Cu}_2\text{O}_8$ develops magnetic order at about 137K and becomes a superconductor at lower temperatures ($T_{SC} \sim 40\text{K}$). T_{SC} decreases with increasing Fe doping in $\text{RuGd}_2\text{Sr}_2(\text{Cu}_{1-x}\text{Fe}_x)_2\text{O}_8$ and is zero by $x = .03$. We measure the ^{99}Ru and ^{57}Fe Mössbauer Effects for $x=0, 0.1, 0.2$, and 0.3 . The ^{57}Fe Mössbauer spectra (MS) show that there are two different Fe sites at 4.2K with very similar hyperfine magnetic fields, $H_{\text{hyper}} \sim 48\text{ T}$. However H_{hyper} goes to zero at $\sim$ half the Fe sites in a temperature range between 30K and 40K in superconducting and non-superconducting samples. There is no significant change in H_{hyper} in the ^{99}Ru MS in this temperature range. We conclude that the Fe sites whose H_{hyper} does not change are in the magnetically ordered RuO planes. We assume that the Fe's which see the transition between 30K and 40K are in the CuO planes and investigate how this transition arises.

¹The work was supported by USDOE(DE-FG02-03ER46064) at BSC and by NSF-DMR-085335 at SDSU.

4:30PM T21.00011 NMR Studies of the pseudogap in BSCCO-2212, J. CROCKER, A.P. DIOGUARDI, N. APROBERTS-WARREN, A.C. SHOCKLEY, UC Davis, H.-J. GRAFE, IFW Dresden, Z. XU, J. WEN, G. GU, BNL, N.J. CURRO, UC Davis — We present O-17 NMR measurements on a single crystal of overdoped BSCCO-2212 ($T_c = 82\text{K}$). As a function of temperature we measure the planar oxygen's: resonance linewidths, Knight shift (K), electronic field gradient (EFG), and spin lattice relaxation rate ($1/T_1$) along each principle axis. Our analysis shows that their temperature dependence can be explained by a suppression of the density of states in the pseudogap region $T < T^* = 94\text{K}$.

4:42PM T21.00012 ^{17}O and ^{199}Hg NMR measurements of $\text{HgBa}_2\text{CuO}_{4+y}$ single crystals¹, A.M. MOUNCE, S. OH, W.P. HALPERIN, Northwestern University, P.L. KUHNS, A.P. REYES, National High Magnetic Field Laboratory, D. XIA, X. ZHAO, University of Minnesota, Jilin University, M. CHAN, L. JI, M. GREVEN, University of Minnesota — The high superconducting transition temperature and the simple tetragonal structure of $\text{HgBa}_2\text{CuO}_{4+y}$ ($\text{Hg}1201$) makes this material an ideal candidate to study unconventional superconductivity in the cuprates[1]. Nuclear magnet resonance has been performed on $\text{Hg}1201$ single crystals which have been annealed in an ^{17}O atmosphere to various dopings. Preliminary results of the NMR spectra and relaxation of both ^{17}O and ^{199}Hg are presented. Narrow linewidths allow for the resolution of both ^{17}O lattice sites and a doping dependent ^{199}Hg spectral splitting[2]. This work is supported by DOE/BES: DE-FG02-05ER46248 and the NHMFL by NSF and the State of Florida.[1] N. Barišić *et al*, PRB **78**, 054518 (2008) [2] J. Haase *et al*, arXiv:1110.601v1 (2011)

¹This work is supported by DOE/BES: DE-FG02-05ER46248 and the NHMFL by NSF and the State of Florida.

4:54PM T21.00013 Magnetic susceptibility analysis on Zn-doping in the high T_c superconductor $\text{YBa}_2\text{Cu}_3\text{O}_{7-1}$, ZACHARY C.M. WINTER, MICHAEL G. SMITH, ALWYN REBELLO, JOHN J. NEUMEIER, Montana State University — Localized magnetic moments are known to destroy superconductivity in conventional superconductors. In the case of $\text{YBa}_2\text{Cu}_3\text{O}_7$ (YBCO), the nonmagnetic ion Zn has a very strong impact on suppressing the superconducting transition temperature (T_c). YBCO loses all superconductivity when only 10% of the Cu is substituted with Zn.² In this project, we have investigated the magnetic susceptibility for a number of Zn doping levels in samples with the nominal composition $\text{YBa}_2(\text{Cu}_{1-x}\text{Zn}_x)_3\text{O}_7$. We observe the development of Curie-Weiss paramagnetism for some Zn compositions, and will address whether the associated paramagnetic moments might cause magnetic pair-breaking.

5:06PM T21.00014 Observable NMR signal from orbital current order in YBCO, SAMUEL LEDERER, STEVEN KIVELSON, Stanford University — Assuming, as suggested by recent neutron scattering experiments, that a broken symmetry state with orbital current order occurs in the pseudo-gap phase of the cuprate superconductors, we show that there must be associated equilibrium magnetic fields at various atomic sites in the unit cell, which should be detectable by NMR experiments.

5:18PM T21.00015 Numerical study of magnetic excitations probed by photon spectroscopies in families of high-temperature superconductors, CHUNJING JIA, CHENG-CHIEN CHEN, BRIAN MORITZ, ADAM SORINI, THOMAS DEVEREAUX, SIMES, SLAC National Accelerator Laboratory and Stanford University — Magnetic excitation in high-temperature superconductors has been a topic of cutting edge research for many years. In photon spectroscopies, single- and two-magnon excitations can be created and measured efficiently using techniques such as resonant inelastic x-ray scattering and optical Raman scattering. We present numerical studies of the magnetic excitations for different families of high-temperature superconductors, including both copper and iron based superconductors. These magnetic excitations and their dispersions provide important information in understanding the magnetic properties of these materials.

Session T22 DMP DCOMP: Focus Session: Fe-based Superconductivity - Properties of 122 phases 254B

2:30PM T22.00001 Combined effects of chemical doping and pressure on physical properties of CaFe_2As_2 ¹, SHENG RAN, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory U.S. DOE and Department of Physics and Astronomy, Iowa State University, MILTON TORIKACHVILI, Department of Physics, San Diego State University — The AFe_2As_2 compounds (A = alkaline earth) are the most extensively studied materials among the FeAs-based superconductors, and CaFe_2As_2 is the most pressure sensitive among them. The structural/magnetic phase transition near 170K is suppressed rapidly under pressure and a nonmagnetic, collapsed tetragonal phase is stabilized. Depending on the hydrostaticity of the pressure medium, the superconducting phase may or may not be induced. In this talk we will present the combined effects of chemical doping and pressure on the structural/magnetic phase transition as well as the collapsed tetragonal structure phase transition in an attempt to better understand the interactions between these phases.

¹Supported by U.S. DOE (DE-AC02-07CH11358), AFOSR-MURI (FA9550-09-1-0603), and NSF (DMR-0805335).

2:42PM T22.00002 First Principles Calculations of the Pnictide CaFe_2As_2 under Pressure, KHANDKER QUADER, Kent State University, MICHAEL WIDOM, Carnegie-Mellon University — We carry out first principles calculations of the effects of pressure on the structural and magnetic properties of the pnictide CaFe_2As_2 and compare with experiments. Our PBE-GGA calculations accurately reproduce the experimentally observed structural and magnetic ordering at zero pressure. Enthalpic considerations show that antiferromagnetic orthorhombic phase is favored over the non-magnetic tetragonal phase at pressure $P=0$, while the “collapsed” tetragonal phase is favored for pressures greater than 0.4 GPa, in good agreement with experiments. The calculated pressure dependences of the lattice parameters and the Fe-As bond lengths agree with experimental trends. We will discuss the nature of bonding and antibonding orbitals near the Fermi surface and we will evaluate the interplanar magnetic exchange interaction J.

2:54PM T22.00003 Evidence for domain wall superconductivity in antiferromagnetic CaFe_2As_2 , ADAM P. DIOGUARDI, UC Davis Physics, HONG XIAO, T. HU, Department of Physics, University of Crete and FORTH, NICHOLAS APROBERTS-WARREN, ABIGAIL SHOCKLEY, JOHN CROCKER, DAVID M. NISSON, Department of Physics, UC Davis, Z. VISKADOURAKIS, Department of Physics, University of Crete and FORTH, XIANYANG TEE, Division of Physics and Applied Physics, Nanyang Technology University, I. RADULOV, Department of Physics, University of Crete and FORTH, C.C. ALMASAN, Department of Physics, Kent State University, NICHOLAS J. CURRO, Department of Physics, UC Davis, CHRISTOS PANAGOPOULOS, Department of Physics, University of Crete and FORTH — ⁷⁵As nuclear magnetic resonance (NMR), resistivity, and magnetization measurements in the antiferromagnetic state of the iron-based superconductor parent compound CaFe_2As_2 exhibit anomalous features consistent with the collective freezing of domain walls. Below $T^* \approx 10$ K, the ⁷⁵As NMR measurements reveal the presence of low fluctuations of the hyperfine field, the resistivity shows an enhancement and subsequent suppression, and the bulk magnetization shows a sharp increase. These features in both the charge and spin response are strongly field dependent, are fully suppressed by $H^* \approx 15$ T, and suggest the presence of filamentary superconductivity nucleated at the antiphase domain walls.

3:06PM T22.00004 Local atomic structure of BaFe_2As_2 by neutron powder diffraction, JENNIFER NIEDZIELA, Dept. of Physics and Astronomy, U. Tennessee, Knoxville; ORNL - Neutron Sciences Directorate, TAKESHI EGAMI, Dept. of Mat. Science and Engineering, Dept. of Physics and Astronomy, U. Tennessee, Knoxville; ORNL - Joint Institute for Neutron Sciences — All structures of iron-based superconductors (FeSC) have planar layers of iron, tetrahedrally coordinated by pnictogens or chalcogens, and the structural details of this layer impact the superconducting and magnetic properties. Local structural studies of the iron-coordinated layer show evidence for local distortions resulting from models that allow for overall reductions in local symmetry. BaFe_2As_2 , a parent compound of several families of FeSC, undergoes a transition at $T \approx 140$ K, resulting in the onset of AFM ordering following a small lattice distortion. Here we report the results of a by time of flight neutron diffraction study on BaFe_2As_2 , analyzed using Rietveld and pair distribution function techniques. This work produces a comprehensive view of the local structure of BaFe_2As_2 as a function of temperature. The results are consistent with previous work showing stratification of the As-As bond length, and show that models accounting for an overall reduction in local symmetry provide the best fit to the experimental data. Further, the results show that local distortions are present up to room temperature. Details of the experiment and implications for the paramagnetic and magnetic states will be discussed.

3:18PM T22.00005 First principles study of uniaxial pressure-induced phase transitions in CaFe_2As_2 and BaFe_2As_2 , ROSER VALENTI, MILAN TOMIC, HARALD O. JESCHKE, Institut fuer Theoretische Physik, Goethe Universitaet Frankfurt, 60438 Frankfurt, Germany — We consider density functional theory methods to determine the equilibrium structures of CaFe_2As_2 and BaFe_2As_2 under the effect of uniaxial pressure. We compare the results with calculations for hydrostatic pressure as well as with available experimental results. In CaFe_2As_2 , we observe a unique phase transition from a magnetic orthorhombic phase to a nonmagnetic collapsed tetragonal phase for both pressure conditions and no indication of a tetragonal phase at intermediate uniaxial pressures. In contrast, for both uniaxial and hydrostatic pressure, BaFe_2As_2 shows two phase transitions from a magnetic orthorhombic to a collapsed tetragonal phase through an intermediate nonmagnetic tetragonal phase. We predict the critical transition pressures under uniaxial conditions to be much lower than those under hydrostatic conditions which implies that the systems are highly sensitive to uniaxial stress. We compare our results to available experimental measurements.

3:30PM T22.00006 Temperature-Pressure Phase Diagram of Lightly Hole-doped BaFe_2As_2 ¹, BALAZS SIPOS, ATHENA SAFA-SEFAT, BRIAN C. SALES, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831 USA, CORRELATED ELECTRON MATERIALS GROUP, MATERIALS SCIENCE AND TECHNOLOGY DIVISION, ORNL TEAM — Chemical doping and application of pressure are the two common tools to tune the electronic structure of a material. Although electron-doping on Fe-site in BaFe_2As_2 gives superconductivity up to ~ 22 K, it is puzzling that hole-doping does not. For this reason, we decided to carry out pressure studies on a few lightly Cr- or Mo-doped crystals of BaFe_2As_2 . We have applied pressures of up to 2 GPa using a cylinder cell, and Fluorinert as pressure medium. Our preliminary findings reveal the shift of antiferromagnetic ordering temperatures to lower with pressure, and a down-turn in resistivity at low temperatures and pressures, which may be attributed to superconductivity.

¹This work was partly supported by the Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division.

3:42PM T22.00007 ABSTRACT WITHDRAWN —

3:54PM T22.00008 Magnetism, superconductivity, and the volume collapse transition in $(\text{Ca}_{0.67}\text{Sr}_{0.33})\text{Fe}_2\text{As}_2$ under pressure¹, JASON JEFFRIES, N.P. BUTCH, Lawrence Livermore National Laboratory, S.R. SAHA, K. KIRSHENBAUM, University of Maryland, S.T. WEIR, Lawrence Livermore National Laboratory, Y.K. VOHRA, University of Alabama, Birmingham, J. PAGLIONE, University of Maryland — The alkaline earth site of CaFe_2As_2 can be chemically substituted with Sr, forming a homogeneous solid solution series ending with SrFe_2As_2 . It is found that $(\text{Ca}_{0.67}\text{Sr}_{0.33})\text{Fe}_2\text{As}_2$ exhibits a pressure-temperature phase diagram intermediate between the two end members of the series, shifting the phase lines for the suppression of magnetism, the development of superconductivity, and the occurrence of a volume collapse transition to higher pressures. The overall shift in the pressure-temperature phase diagram permits the study of each phase field, yielding valuable information about the correlations between local atomic structure, magnetism, superconductivity, and the volume collapse transition. Lawrence Livermore National Laboratory is operated by Lawrence Livermore National Security, LLC, for the U.S. Department of Energy, National Nuclear Security Administration under Contract DE-AC52-07NA27344.

4:06PM T22.00009 Inducing structural collapse and superconductivity in CaFe_2As_2 by systematic substitutions of rare earths, SHANTA SAHA, TYLER DRYE, NICHOLAS BUTCH, RONGWEI HU, KEVIN KIRSHENBAUM, STEVEN ZIEMAK, JOHNPierre PAGLIONE, Center for Nanophysics and Advanced Materials, Dept. of Physics, University of Maryland, College Park, MD 20742, PETER ZAVALIJ, Dept. of Chemistry and Biochemistry, University of Maryland, College Park, MD 20742, JEFFREY LYNN, NIST Center for Neutron Research, Gaithersburg, MD 20899 — Recently, we have reported structural collapse and 47 K superconductivity in CaFe_2As_2 by aliovalent rare earth substitutions for Ca atoms [1]. We will present the evolution of structural and superconducting properties in single crystals of CaFe_2As_2 by systematic substitutions of R (=La, Ce, Pr, and Nd) for Ca, causing electron doping that is indirect to FeAs layer. Effect of annealing, growth method, etching, and pressure on $\text{Ca}_{1-x}\text{R}_x\text{Fe}_2\text{As}_2$, indicating the intrinsic nature of this high T_c superconductivity, the highest in 122 Fe-based materials, will be discussed. Ref. [1] S. R. Saha *et al.* arXiv:1105.4798.

4:18PM T22.00010 Defect-Associated Superconductivity in $(\text{Pr,Ca})\text{Fe}_2\text{As}_2$, FENGYAN WEI, BING LV, LIANGZI DENG, YANYI SUN, YUYI XUE, Texas Center for superconductivity at University of Houston Department of Physics, CHINGWU CHU, Texas Center for superconductivity at University of Houston Department of Physics, Lawrence Berkeley National Laboratory — The superconductivity in rare earth doped CaFe_2As_2 remains puzzled. As reported before, there are two distinguishable superconductive transitions at 20 K and 49 K, respectively, and the 49 K superconductivity can be better modeled as Josephson-Junction-Arrays (JJA). The H- and T-dependencies of the ac/dc magnetization are further explored here. The data suggest that the effective lower-critical-fields at both *c*- and *ab*-directions are below 1 Oe down to 5 K, in agreement with previous JJA assumption. The ac susceptibility below the critical field is highly anisotropy, suggesting a thin-disk-like morphology of the JJA's. The associated weak-links, however, appear to be broken above 20 K by a *dc* bias as small as 10 Oe. The ac response at higher bias fields, therefore, will be dominated by the isolated superconducting islands of JJA. It is interesting to note, therefore, that the ac susceptibility remains highly anisotropic at high fields, but is much weaker than that expected from the field-cooled magnetization. We interpret this as the result of sub-micron size, thin-disk-like local superconductivity, *i.e.* Defect-associated superconductivity.

4:30PM T22.00011 Rare Earth Doping in the $(\text{Sr,Ca})\text{Fe}_2\text{As}_2$ System, TYLER DRYE, SHANTA SAHA, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland-College Park, PETER ZAVALIJ, Department of Chemistry, University of Maryland-College Park, JOHNPierre PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland-College Park — The $(\text{Sr,Ca})\text{Fe}_2\text{As}_2$ system shows an unusual persistence of the Neel ordering temperature of ~ 200 K up to a concentration of 70% calcium. We present electrical transport, magnetic susceptibility and structural characterization data as a function of rare earth substitution into $\text{Sr}_{0.3}\text{Ca}_{0.7}\text{Fe}_2\text{As}_2$ single crystals, focusing on the resultant phase diagram and the comparisons of solubility limit of rare earth substitution as compared to end members SrFe_2As_2 and CaFe_2As_2 .

4:42PM T22.00012 Microstructure and the non-bulk superconductivity up to 49K in electron-doped Rare-earth $(\text{Ca, R})\text{Fe}_2\text{As}_2$ (R=La, Ce, Pr and Nd) Single Crystals, BING LV, FENGYAN WEI, LIANGZI DENG, YANYI SUN, YU-YI XUE, MELISSA GOOCH, TCSUH and Department of Physics, University of Houston, JAMES MEEN, TCSUH and Department of Chemistry, University of Houston, CHING-WU CHU¹, TCSUH and Department of Physics, University of Houston — In an attempt to raise the T_c in the 122 family, we have carried out electron-doping and observed an onset T_c up to 49K in the single crystalline $(\text{Ca, R})\text{Fe}_2\text{As}_2$ (R=La, Ce, Pr and Nd). The single crystals up to 5 × 5 mm size are grown from self-flux technique and the optimal doping parameters for different rare-earth elements will be reported. Magnetic and resistivity data suggest possible existence of two superconducting transitions in all the rare-earth electron doped $(\text{Ca, R})\text{Fe}_2\text{As}_2$ samples: one starts at ~ 40 s K, and the other at ~ 20 K, with drastically different response to the field. Detailed single crystals diffraction analysis show that there are no significant difference in terms of atomic position, bond distances, angles and lattice parameters upon different rare earth doping; the defect-related local structure might be responsible for the observed high T_c in this system. The unusual superconducting phase appears to be filamentary or interfacial in nature, and the possible mechanism will be discussed.

4:54PM T22.00013 Codoping – A way to enhance the upper critical field in iron-arsenic superconductors¹, M. NICKLAS, MPI for Chemical Physics of Solids, Dresden, Germany, F. WEICKERT, LANL, MPA-CMMS, Los Alamos, NM, USA, J. WOSNITZA, HLD, HZDR, Dresden, Germany, A. LEITHE-JASPER, W. SCHNELLE, H. ROSNER, MPI for Chemical Physics of Solids, Dresden, Germany — Technological key features of iron-based superconductors are the high critical temperature T_c of up to 55 K and the high tolerance against magnetic fields, which led so far to upper critical fields in the range of 75 T. Furthermore, the small H_{c2} -anisotropy between field applied along the *c*-direction and in the *ab*-plane, in particular for the FeSe and AEFe_2As_2 ($\text{AE} = \text{Ca, Sr, Ba}$) materials, is a prerequisite for several technical applications. Currently, different approaches (chemical substitutions, processing) are discussed how to increase H_{c2} further. Here, we show a feasibility study for codoping of polycrystalline Sr- or BaFe_2As_2 samples, namely the simultaneous substitution of K on the Sr/Ba layer and of Co on the FeAs layer. The upper critical field was investigated by magnetoresistance in high pulsed magnetic fields up to 64 T. We find, that the extrapolated critical field $H_{c2}(T \rightarrow 0)$ is enhanced by 15% for $\text{Ba}_{0.55}\text{K}_{0.45}\text{Fe}_{1.95}\text{Co}_{0.05}\text{As}_2$ in comparison to $\text{Ba}_{0.55}\text{K}_{0.45}\text{Fe}_2\text{As}_2$, although T_c is almost identical in both materials. These results suggest that codoping is a promising route for the systematic optimization of iron-arsenic based superconductors for high-magnetic field and high-current applications.

5:06PM T22.00014 Influence of random point defects introduced by proton irradiation on the vortex pinning and dynamics of superconducting 122 iron arsenides¹, LEONARDO CIVALE, NESTOR HABERKORN, IGOR USOV, JEEHOON KIM, BORIS MAIOROV, MARCUS WEINGARD, Los Alamos National Laboratory, G.F. CHEN, W. YU, Department of Physics, Renmin University of China, Beijing, China, W. HIRATA, S. MIYASAKA, S. TAJIMA, N. CHIKUMOTO, K. TANABE, Superconductivity Research Laboratory-ISTEC, 1-10-13 Shinonome, Koto-ku, Tokyo 135-0062, Japan — Vortex matter in iron-arsenide superconductors exhibits a rich phenomenology that is still largely unexplored. One way to understand and manipulate the pinning mechanisms and the vortex dynamics in superconductors is by the artificial introduction of additional defects. In this work we explore the influence of the random point defects introduced by proton irradiation on the vortex dynamics and critical currents of 122 iron arsenide superconductors. Our comparison includes $\text{Ca}_{1-x}\text{Na}_x\text{Fe}_2\text{As}_2$ and Co-doped BaFe_2As_2 single crystals. We find that the influence of random point defects on the creep rate (S) and the elastic to plastic crossover of the vortex dynamics show a strong dependence with intrinsic superconductor parameters such as the coherence length. We analyze the magnetic field – temperature (H - T) vortex phase diagrams for the as-grown single crystals and the changes produced by the random point defects.

5:18PM T22.00015 Upper critical and irreversible fields of polycrystalline $\text{CeFeAsO}_{1-x}\text{F}_x$ superconductors, SHEN V. CHONG, JEFFERY L. TALLON, Industrial Research Limited, New Zealand, GRANT V.M. WILLIAMS, The MacDiarmid Institute, Victoria University of Wellington, New Zealand — We have investigated the upper critical (H_{c2}) and irreversible (H_{irr}) fields of polycrystalline samples of Ce oxypnictide at different doping levels. H_{c2} was obtained from temperature dependent resistivity measurements with increasing applied magnetic field. Critical field values as high as 150 Tesla were observed with a decreasing trend as the doping level shifts from a slightly under-doped state to the highly over-doped region. The irreversible fields were lower in this superconductor compared with other rare-earth oxypnictides, with values below 3 Tesla at 20 K. However, H_{irr} was found to increase with increasing doping, opposite to that of H_{c2} . The origin of H_{irr} was studied by determining the exponent 'n' extracted from plots of $\log_{10}(H_{irr})$ versus $\log_{10}(1-T/T_c)^n$. We found that H_{irr} follows a 3D vortex lattice-melting model similar to the other low anisotropic iron-based superconductors.

Wednesday, February 29, 2012 2:30PM - 5:30PM – Session T23 DCMP: Actinides and Transport Magnetism in Metals 255

2:30PM T23.00001 A quantum Monte Carlo study of thorium halide molecules, SHI GUO, MINYI ZHU, North Carolina State University, ENRIQUE BATISTA, RICHARD MARTIN, Los Alamos National Lab, LUBOS MITAS, North Carolina State University — We present electronic structure calculations of thorium halide molecules, namely, a series of ThCl_n and ThBr_n ($n=1,2,3,4$) systems. We calculate the bond dissociation energies for the sequence of the following dissociation reactions: $\text{ThCl}_n \rightarrow \text{ThCl}_{n-1} + \text{Cl}$ and $\text{ThBr}_n \rightarrow \text{ThBr}_{n-1} + \text{Br}$. We apply both large core and small core energy-consistent pseudopotentials for thorium atom and we employ DFT GGA and hybrid functionals for energies and geometry calculations. For high accuracy energies we use the fixed-node diffusion Monte Carlo (DMC) method. In DMC calculations we employ both single- and multi-reference trial wave functions in order to test the quality of the nodal surfaces. We study the dissociation energies with regard to different multiplicities of the ThX_n molecules and the different behavior of the bromides with respect to chlorides. We compare our results with hybrid DFT methods and experimental values. Supported by DOE and NSF.

2:42PM T23.00002 Electron binding energy of uranium-ligand and uranyl-ligand anions¹, LEI WANG, STEVEN HOROWITZ, BRAD MARSTON, Brown University — Electron binding energies of the early actinide element uranium in gas-phase anion complexes are calculated by relativistic density functional theory (DFT) with two different exchange-correlation functions (RPBE and B3LYP) and also in the Hartree-Fock (HF) approximation². Scalar and spin-orbit calculations are performed, and the calculated energies are compared to available experimental measurements and shown to disagree by energies of order 1 eV. Strong correlations that are poorly treated in DFT and HF can be included by a hybrid approach in which a generalized Anderson impurity model is numerically diagonalized. Reduction-oxidation (redox) potentials of aqueous actinide ions show improved agreement with measured values in the hybrid approach³. We test whether or not similar improvements are found in the gas-phase.

2:54PM T23.00003 Electronic structure of Pu metal and intermetallics as determined by ARPES and XPS¹, MILES BEAUX, TOMASZ DURAKIEWICZ, KEVIN GRAHAM, JEREMY MITCHELL, SCOTT RICHMOND, ERIC BAUER, DAVID MOORE, FRANZ FREIBERT, PAUL TOBASH, JOHN KENNISON, JOHN JOYCE, Los Alamos National Laboratory — We exploit our unique capability in angle resolved photoemission (ARPES) measurement for plutonium materials to compare the electronic structure of delta Pu, PuCoIn_5 and PuCoGa_5 . We present a systematic study for polycrystalline delta Pu metal as well as the first photoemission measurements on single crystals of the superconductor PuCoIn_5 . These first results for PuCoIn_5 are compared to results for PuCoGa_5 and variations in the electronic structure are attributed to differences in 5f hybridization with conduction states based on differences in lattice values. Laser ablation was used to clean the surface of Pu materials and cleanliness was monitored through O 1s and Pu 4f core levels as well as valence band features. Observation of these spectra provides better insight into the differentiation of contaminant features versus the strong correlation effects within Pu metal.

3:06PM T23.00004 Elastic moduli of nearly pure polycrystalline plutonium, ALBERT MIGLIORI, ARKADY SHEKHTER, JON B. BETTS, VICTOR FANELLI, NHMFL, Pulsed Field facility, LANL, Los Alamos, NM — We measure elastic moduli of microalloyed polycrystalline cylindrical specimen of Pu-239. We observe $\alpha \rightarrow \beta \rightarrow \gamma \rightarrow \delta$ phase transitions and find that the elastic moduli of nearly pure plutonium are the same as those of Ga-stabilized plutonium.

3:18PM T23.00005 Magnetization at 1 Mbar Near the Tricritical Point in the Ce(0.9- x)La(x)Th(0.10) System¹, J.L. SMITH, K. GOFRYK, R.D. TAYLOR, J.C. LASHLEY, Los Alamos National Lab, M.P. PASTERNAK, Tel Aviv University, D.J. POLANCIC, Quantum Design, Inc. — The gamma to alpha isostructural transition in the Ce(0.9- x)La(x)Th(0.10) system is measured as a function of La alloying and external pressure up to 1 Mbar using magnetic susceptibility. We probe a line of discontinuous transitions, as indicated by the change in volume, decreasing exponentially from 118 K to close to 0 K with increasing La doping, and the transition changes from being first order to continuous at a critical concentration close to $x = 0.14$. At the tricritical point, the magnetic susceptibility increase rapidly near the critical concentration and approaches large values at $x = 0.35$ signifying that a heavy Fermi-liquid state evolves at large doping near the critical concentration. The Wilson ratio reaches a value above two for a narrow range of concentrations where the specific heat and susceptibility vary most rapidly with the doping concentration.

3:30PM T23.00006 ABSTRACT WITHDRAWN —

3:42PM T23.00007 Actinide oxides under pressure, LEON PETIT, Daresbury Laboratory, MALCOLM STOCKS, Oak Ridge National Laboratory, MARTIN LUEDERS, ZDZISLAWA SZOTEK, WALTER TEMMERMAN, Daresbury Laboratory, AXEL SVANE, Aarhus University — We use the self-interaction corrected local spin density approximation to investigate the oxidation of actinide dioxides under pressure. The methodology enables us to determine the ground state valency configuration of the actinide 5f electrons and to study the localization/delocalization transition that occurs under pressure. We argue that this delocalization facilitates the oxidation of the actinide dioxides and present results for the estimated transition pressures.

3:54PM T23.00008 Dephasing due to electron interactions in inhomogeneous systems, MAXIMILIAN TREIBER, OLEG YEVTUSHENKO, JAN VON DELFT, Ludwig-Maximilians-University, Physics Department, ASC, CeNS, Theresienstrasse 37, D-80333 Munich, Germany — At sufficiently low temperatures, the dephasing time τ_φ of mesoscopic samples is governed by so-called Johnson-Nyquist (electronic) noise. We study the spatial dependence of the corresponding noise correlation function (NCF) in inhomogeneous systems. Using the fluctuation-dissipation theorem and the random-phase approximation, we derive a real-space integro-differential equation for the NCF and show that it reduces to a diffusion equation in the case of strong screening. In particular, using a method based on the spectral determinant, we evaluate the NCF for arbitrary networks of quasi-1D disordered wires with boundary conditions. As an application, we construct a realistic quantum dot model via a set of parallel wires connected at contacts to leads, and calculate the temperature dependence of τ_φ as well as the quantum corrections to the conductance. Furthermore, we analyze the observability of the elusive 0D regime (reached at $T < E_{\text{Thouless}}$ with the characteristic $\tau_\varphi \propto T^{-2}$ behavior) in such systems, and discuss alternative scenarios of its observation.

4:06PM T23.00009 Does aluminum conduct better than copper at the nanoscale? A first-principles study of metallic nanowires¹, ADAM SIMBECK, NICK LANZILLO, NEERAV KHARCHI, SAROJ NAYAK, Rensselaer Polytechnic Institute — From first-principles, we present a theoretical and comparative investigation of the role of quantum confinement in altering the electronic, transport, and phonon properties of linear, single-atom thick chains, i.e. nanowires, of metallic (Au, Ag, Cu, and Al) atoms. Our results for the ballistic quantum transport properties and electronic structure are in perfect agreement with those previously published. Motivated by this, we also consider electron-phonon interactions in such devices, where we report an order of magnitude reduction in the electron-phonon coupling constant for Al, whereas an enhancement is predicted for Au, Ag, and Cu.

4:18PM T23.00010 Quantum oscillations and low-T resistivity of the 5s delafossite PdCoO₂¹, CLIFFORD HICKS, ALEXANDRA GIBBS, ANDREW MACKENZIE, University of St Andrews, U.K., HIROSHI TAKATSU, Tokyo Metropolitan University, Japan, YOSHITERU MAENO, Kyoto University, Japan, EDWARD YELLAND, University of St Andrews, U.K. — We report dHvA torque and resistivity data on the highly conductive delafossite PdCoO₂. Quantum oscillations confirm electronic structure calculations in showing a single, highly 2D Fermi surface with almost exactly half filling. However the cyclotron masses and the details of the warping are consistent with PdCoO₂ being a 5s metal, rather than the 4d metal indicated in most electronic structure papers. The room temperature resistivity is $\rho_{ab} = 2.6 \pm 0.2 \mu\Omega\text{-cm}$, lower than all elemental metals apart from the noble metals. The low-T residual resistivity of our samples is $0.008 \mu\Omega\text{-cm}$, corresponding to an extremely long mean free path of $20 \mu\text{m}$, surprising for a flux-grown material. The temperature dependence of the electron-phonon contribution to the resistivity is exponential rather than T^5 , indicating phonon drag, and the only observation of phonon drag in resistivity outside the alkali metals.

4:30PM T23.00011 Dielectric function of Ni-Pt alloys from 0.6 to 6.6 eV by spectroscopic ellipsometry¹, LINA ABDALLAH, STEFAN ZOLLNER, TAREK TAWALBEH, IGOR VASILIEV, NMSU, CHRISTIAN LAVOIE, AHMET OZCAN, IBM, MARK RAYMOND, GLOBALFOUNDRIES — The complex dielectric function of different Ni-Pt alloys (10% to 25% Pt concentration, 10nm thickness) was determined using spectroscopic ellipsometry over a broad photon energy range from 0.6 to 6.6eV. The films were deposited on a thick SiO₂ layers using Si as a substrate. The data were fitted using previously determined optical constants for Si and SiO₂. Optical constants of the Ni-Pt alloys were described using a Drude model (free carrier term), a pole due to d-intraband transition, and 2 to 3 Lorentz oscillators due to interband transitions. Data were compared with the calculated band structure of Nickel and Platinum. Results showed only small changes with the variation of Pt concentration or with annealing at 500 °C for 30s.

¹NSF DMR-1104934

4:42PM T23.00012 The Role of d -Orbitals in the Rashba Splitting on Au(111) and Ag(111), HYUNJUN LEE, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — We investigate the Rashba-type spin splitting in sp -derived Shockley surface states on (111) surfaces of noble metals, such as Au(111) and Ag(111), based on first-principles calculations including the spin-orbit interaction. By turning on and off l -dependent spin-orbit coupling one by one, we find that although the surface states on Au(111) have predominantly p -orbital character, the spin splitting in energy originates mainly from d -orbital character of the surface states. We also demonstrate that the spin splitting in surface states of both metallic surfaces of Au(111) and Ag(111) can be controlled by varying the sizes of d -orbital parts of the surface-state wave functions. These results show that in addition to difference in the atomic spin-orbit strength in Au and Ag, difference in d -orbital contributions to the surface states makes substantial difference in the sizes of the Rashba-type spin splitting in their surface electronic structures. This work was supported by the NRF of Korea (Grant Nos. 2009-0081204 and 2011-0018306) and KISTI Supercomputing Center (Project No. KSC-2011-C2-04).

4:54PM T23.00013 Effects of Co doping on the metamagnetic states in fcc $\text{Fe}_{1-x}\text{Co}_x$ ¹, ROMEO DE COSS, FILIBERTO ORTIZ-CHI, Departamento de Física Aplicada, Cinvestav-Merida, Yucatán, Mexico — It is well known that fcc-Fe have shows meta-magnetism, with a low-spin state (LS) at small volume and a high-spin state (HS) at large volume in the total-energy vs volume curve. In this work, we have studied the evolution of the metamagnetic states in the $\text{Fe}_{1-x}\text{Co}_x$ alloy as a function of Co concentration by means of first principles calculations. The ground state properties were obtained using the Full-Potential Linear Augmented Plane Waves method and the Generalized Gradient Approximation for the exchange-correlation functional. The alloying was modeled using the self-consistent virtual crystal approximation. The magnetic states are obtained from the total-energy as a function of the spin moment calculations, obtained using the Fixed Spin Moment methodology. For fcc-Fe, we found that the ground state corresponds to the LS state. Increasing the Co concentration the HS state decrease in energy. Thus, for $x = 0.05$ the energy of the LS and HS states is practically the same, corresponding to a spin-glass state. The LS state is substituted by a paramagnetic state for $x > 0.3$ of Co concentration. Interestingly, for the alloy with $x \sim 0.35$ the total-energy vs volume curve shows “effective symmetry,” which is expected to exhibit invar behavior.

¹This research was supported by Conacyt-Mexico under Grant No. 83604.

5:06PM T23.00014 Investigation of Possible Phase Separation in Rapidly Quenched $\text{Fe}_{1-x}\text{Co}_x$ Alloys with Cluster Expansion Model, XIN ZHAO, MANH CUONG NGUYEN, MIN JI, IVER E. ANDERSON, M.J. KRAMER, R. WILLIAM MCCALLUM, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University — Recently, experiments observed phase separation in rapidly quenched $\text{Fe}_{1-x}\text{Co}_x$ alloy in the ordered α' phase [J. Alloys Compd. 424, 145 (2006)]. It is also believed that this is not an equilibrium result because of phase rule violation in the published phase diagram. To clarify this situation, we calculate the phase diagram of the system using cluster expansion in combination with a genetic algorithm. We calculated free energy of the system using super-cells up to 32 atoms with compositions ranging from 35 to 100 at. % Fe. Possible explanations for the experimental observations will be discussed.

5:18PM T23.00015 Atomic Structures and Magnetic Properties of Fe-rich $\text{Fe}_{1-x}\text{Co}_x$ Alloys: A Genetic Algorithm Search, MANH CUONG NGUYEN, XIN ZHAO, MIN JI, BRUCE HARMON, CAI-ZHUANG WANG, KAI-MING HO, Ames Laboratory, US DOE and Department of Physics and Astronomy, Iowa State University — Using genetic algorithm with first-principles calculations, we performed a broad global search for low-energy crystal structures of Fe-rich $\text{Fe}_{1-x}\text{Co}_x$ alloys. We found that Fe-rich $\text{Fe}_{1-x}\text{Co}_x$ alloys are highly configurationally degenerate and there are many additional off-stoichiometric stable structures to the well-known stoichiometric FeCo - B_2 structure, giving a possibility for atomistic manipulation of the alloys. The Co-Co nearest-neighbor pair is strongly unfavorable in Fe-rich $\text{Fe}_{1-x}\text{Co}_x$ alloys. The magnetic moment of Fe atom is increasing with Co concentration while that of Co atom is almost constant, inducing a Slater-Pauling curve for magnetic moment per atom. The magnetic moment of Fe atom is strongly dependent on the number of Co nearest-neighbors and it increases with this number.

Wednesday, February 29, 2012 2:30PM - 5:42PM – Session T24 FIAP: Fractional Quantum Hall Effect III 256

2:30PM T24.00001 Evolution of 7/2 fractional quantum Hall state in two subband systems¹, YANG LIU, JAVAD SHABANI, D. KAMBUROV, M. SHAYEGAN, L.N. PFEIFFER, K.W. WEST, K.W. BALDWIN, Electrical engineering, Princeton University — We report the evolution of the fractional quantum Hall state (FQHS) at total Landau level (LL) filling factor $\nu = 7/2$ in wide GaAs quantum wells in which electrons occupy two electric subbands. The data reveal subtle and distinct evolutions as a function of density, magnetic field tilt-angle, or symmetry of the charge distribution. At intermediate tilt angles, for example, we observe a strengthening of the $\nu = 7/2$ FQHS. Moreover, in a well with asymmetric charge distribution, there is a developing FQHS when the LL filling factor of the symmetric subband ν_S equals 5/2 while the antisymmetric subband has filling $1 < \nu_A < 2$.

¹We acknowledge support through DOE BES (DEFG0200-ER45841) for measurements, and the Moore Foundation and the NSF (DMR-0904117 and MRSEC DMR-0819860) for sample fabrication and characterization.

2:42PM T24.00002 Observation of reentrant quantum Hall states in the lowest Landau level¹, M. SHAYEGAN, YANG LIU, C.G. PAPPAS, L.N. PFEIFFER, K.W. WEST, K.W. BALDWIN, Electrical engineering, Princeton university — Measurements in very low disorder two-dimensional electrons confined to relatively wide GaAs quantum well samples with tunable density reveal reentrant $\nu = 1$ integer quantum Hall states in the lowest Landau level near filling factors $\nu = 4/5$ and $6/5$. These states are not seen at low densities and become more prominent with increasing density and in wider wells. Our data suggest that these reentrant phases are (bubble) Wigner crystal states, stabilized here in the lowest Landau level thanks to the large electron layer thickness.

¹We acknowledge support through the Moore Foundation and the NSF (DMR-0904117 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG0200-ER45841) for measurements.

2:54PM T24.00003 Spin waves in the second Landau level: Probing the spin-polarization enigma¹, URSULA WURSTBAUER, TREVOR DAVID RHONE, ARON PINCZUK, Columbia University, KEN W. WEST, LOREN N. PFEIFFER, Princeton University — The physics in the second Landau level (SLL) is governed by competing phases resulting in striking phenomena. We use resonant inelastic light scattering experiments to explore collective excitation modes with the focus on low lying spin excitation modes in the SLL. The intensity of the small momentum spin-wave at the bare Zeeman energy (E_Z) collapses for filling factors away from integer filling factor $\nu < 3$ and are dominated by a continuum of modes. We find that at the fractional filling factors $14/5$, $8/3$, $5/2$, $7/3$, $11/5$ the continuum coexists with a weak but distinct signal at E_Z , a long wavelength spin-wave that suggests a degree of spin polarization. In addition, at $5/2$ an intriguing well developed sharp mode is observable below E_Z , which is unique for the even-denominator filling factor. Modes at energies larger than E_Z merge additionally at odd-denominator states in ILS spectra, most pronounced for $7/3$, in a manner that is similar to that of the $1/3$ state. This observation could be evidence that the CF framework could be applicable to these states.

¹Supported by NSF and AvH

3:06PM T24.00004 Ballistic transport of (001) GaAs two-dimensional holes and hole-flux composite fermions through a lateral strain-induced superlattice¹, DOBROMIR KAMBUROV, HASSAN SHAPOURIAN, MANSOUR SHAYEGAN, LOREN PFEIFFER, KEN WEST, KIRK BALDWIN, Princeton University — The addition of a unidirectional superlattice on the surface of high-mobility two-dimensional carrier systems leads to a potential modulation signaled by the observation of magnetoresistance commensurability oscillations. We present measurements in high-mobility, two-dimensional (001) GaAs systems patterned with strain-induced surface superlattices of periodicity 100 to 250 nm. The data exhibit pronounced commensurability oscillations of holes near zero magnetic field and of hole-flux composite fermions near filling factor $\nu = 1/2$, allowing us to probe the Fermi contours of these quasi-particles.

¹We acknowledge support through the NSF (ECCS-1001719 and MRSEC DMR-0819860) for sample fabrication and characterization, and the DOE BES (DE-FG0200-ER45841) for measurements.

3:18PM T24.00005 Microscopic Disorder-Based model for non-Abelian Quasi-Particles in $\nu = 5/2$ FQH states¹, GILAD BEN-SHACH, CHRIS R. LAUMANN, AMIR YACOBY, BERTRAND I. HALPERIN, Harvard University — The detection of non-Abelian quasiparticles remains an outstanding experimental problem in the $\nu = \frac{5}{2}$ fractional quantum Hall (FQH) state. The presence of non-Abelian statistics would lead to additional low energy states in the system, and hence an additional low-temperature entropy. One approach to test for non-Abelian quasiparticle statistics uses thermodynamic measurements to detect this entropy contribution [1,2]. We present a microscopic model for quasiparticles in the $\nu = \frac{5}{2}$ FQH state with a disorder potential that fluctuates on the order of several magnetic lengths, and attempt to determine the feasibility of the experiments proposed in [1], based on local probe measurements of incompressibility [3].

3:30PM T24.00006 Correlating scattering times with the strength of the $\nu=5/2$ fractional quantum Hall state, SUMIT MONDAL, Department of Physics, Purdue University, JOHN WATSON, Birck Nanotechnology Center and Department of Physics, Purdue University, GEOFFREY GARDNER, Birck Nanotechnology Center and School of Materials Engineering, Purdue University, NODAR SAMKHARADZE, GABOR CSATHY, Department of Physics, Purdue University, MICHAEL MANFRA, Department of Physics, Birck Nanotechnology Center and Schools of Materials and Electrical and Computer Engineering, Purdue University — There is widespread interest in the fractional quantum Hall effect at $\nu=5/2$. Theory predicts that the state at $\nu=5/2$ may possess non-Abelian braiding statistics. Experimental interrogation remains difficult due to the fragility of the excitation gaps requiring both high quality samples and examination at low temperatures. Mounting evidence suggests that the strength of the most fragile fractional quantum Hall states in the 2nd Landau level including $\nu=5/2$ are poorly correlated with the scattering time extracted from zero-field mobility measurements at higher temperatures. It is also unclear if the quantum scattering time derived from analysis of the low-field Shubnikov de-Haas oscillations provides any additional information relevant to prediction of the strengths of the observed fractional states. We report on a systematic attempt to correlate the T=0.3K behavior of the mobility lifetime, quantum scattering time, and an effective high field mobility lifetime evaluated at $\nu=5/2$ with the measured activation gap. We will present results from a number of heterostructure designs over a wide span of zero-field mobility ranging from $\sim 10 \times 10^6 \text{ cm}^2/\text{Vs}$ to greater than $20 \times 10^6 \text{ cm}^2/\text{Vs}$.

3:42PM T24.00007 “Perfect” Coulomb Drag in a Bilayer Quantum Hall System¹, D. NANDI, A.D.K. FINCK, J.P. EISENSTEIN, California Institute of Technology, L.N. PFEIFFER, K.W. WEST, Princeton University — We report Coulomb drag measurements in Corbino geometry which reveal that equal but oppositely directed electrical currents can freely propagate across the insulating bulk of the bilayer quantized Hall state at $\nu_T = 1$ even when the two 2D layers are electrically isolated and interlayer tunneling has been heavily suppressed by an in-plane magnetic field. This effect, which we dub “perfect” Coulomb drag, reflects the transport of charge neutral excitons across the bulk of the 2D system. The equal magnitude of the drive and drag currents is lost at high current and when either the temperature or effective separation between the two 2D layers is increased. In each of these cases, ordinary quasiparticle charge transport across the annulus has grown to dominate over exciton transport.

¹This work was supported by the NSF via grant DMR-1003080.

3:54PM T24.00008 Topological order, quasi-particle statistics and braiding from ground state entanglement, YI ZHANG, TARUN GROVER, University of California, Berkeley, ARI TURNER, University of Amsterdam, MASAKI OSHIKAWA, Institute for Solid State Physics, University of Tokyo, ASHVIN VISHWANATH, University of California, Berkeley — Topologically ordered phases are gapped states, defined by the properties of excitations when taken around each other. By calculating Topological Entanglement Entropy (TEE) of a disc shaped partition using a Monte Carlo technique, we establish the existence of topological order in $SU(2)$ symmetric gapped spin liquids and lattice Laughlin states obtained by the Gutzwiller projection technique. On the other hand, the TEE of partitioning the torus into two cylinders is generally different and depends on the chosen ground state. We demonstrate a method to extract the statistics and braiding of excitations, given just the set of ground state wave-functions on a torus. Central to our scheme is the identification of groundstates with minimum entanglement entropy, which reflect the quasi-particle excitations. We demonstrate our method by extracting the modular S matrix of an $SU(2)$ symmetric chiral spin liquid, and prove that its quasi-particles obey semionic statistics. This method offers a route to a nearly complete determination of the topological order in several cases.

4:06PM T24.00009 Paired Quantum Hall States at Weak Coupling: Phenomenology¹, S.A. PARAMESWARAN, University of California, Berkeley, S.A. KIVELSON, Stanford University, S.L. SONDHIL, Princeton University, B.Z. SPIVAK, University of Washington — Paired quantum Hall states such as the Pfaffian exhibit a weak-coupling regime much like that of BCS superconductivity. In this regime their lowest energy excitations are neutral fermions – Bogoliubov quasiparticles constructed from the composite fermions – and not the charged vortices which generally govern the behavior of quantum Hall states. We discuss a rich set of phenomena which follow from this observation. At finite temperatures of order the pairing scale these include (i) an almost sharp phase transition (ii) a new finite-temperature length scale for the penetration of longitudinal electric fields, and (iii) the existence of a new collective excitation in paired QH states which is a cousin to the well known Artemenko-Volkov-Carlson-Goldman-Schmid-Schon mode in conventional superconductors. At lower temperatures, we find (i) a proximity effect between the paired states and their ancestor metals, which in turn mediates (ii) ‘Josephson’ couplings between paired QH droplets separated by metallic regions and leads to (iii) a distinctive response of such states to disorder; and finally, we also comment on (iv) an analog of Andreev reflection in these systems.

¹S.A.P. is supported by a Simons Postdoctoral Fellowship at UC Berkeley.

4:18PM T24.00010 From Luttinger liquid to non-Abelian quantum Hall states¹, JEFFREY C.Y. TEO, University of Illinois at Urbana-Champaign, C.L. KANE, University of Pennsylvania — We formulate a theory of non-Abelian fractional quantum Hall states by considering an array of coupled interacting one dimensional wires, each described by a Luttinger liquid theory. This coupled wire construction provides a solvable Hamiltonian formulated in terms of electronic degrees of freedom, and provides a direct route to characterizing the quasiparticles and edge states in terms of conformal field theory. It also leads to a simple interpretation of the coset construction of conformal field theory, which is a powerful method for describing non-Abelian states. The level- k Read-Rezayi state at filling $\nu = k/(2+qk)$ is constructed by an uneven but periodic magnetic field configuration that organizes the wires into bundles. Gapless degrees of freedom in each bundle are decomposed into conformal sectors, which acquire energy gaps independently by intra-bundle and time reversal breaking inter-bundle interactions.

¹NSF grant DMR-0906175

4:30PM T24.00011 A comparative study of the reentrant integer quantum Hall states in the second and third Landau levels, NIANPEI DENG, JOHN WATSON, MICHAEL MANFRA, GABOR CSATHY, Purdue University — In the two-dimensional electron gas competing electron-electron interactions and disorder effects give rise to many-body ground states such as the fractional quantum Hall and the reentrant integer quantum Hall states (RIQHS). The latter are not yet well understood, but they are believed to be Wigner crystal-like electron solids with one or more electrons at each lattice nodes. We have recently shown that for the RIQHS in the second Landau level one can extract their onset temperature from the temperature-dependent magnetoresistance. We report similar studies of the RIQHS in the third Landau level. To our surprise, the onset temperatures of the RIQHSs in the third Landau level are about a factor of 3 larger than those in the second Landau level. This result clearly shows that the RIQHSs in the second and third Landau level have vastly different cohesion energies and may indicate different internal symmetries for these states. This work was supported by the DOE grant DE-SC0006671.

4:42PM T24.00012 Pomeranchuk Instability driven by Coulomb interaction in half-filled Landau levels, JUNPING SHAO, Cornell University, EDWARD REZAYI, Cal State LA, EUN-AH KIM, Cornell University — We study the Coulomb interaction driven Pomeranchuk instability as a mechanism for observed electronic nematic phases at high Landau levels. Such a mechanism will be signaled by the instability of the Fermi surface to quadrupolar deformations: $F_2 < -1$, where F_2 is the Fermi liquid parameter for the angular momentum $L = 2$ channel. We compare the Fermi Liquid parameters for the lowest three half-filled Landau levels ($\nu = 1/2, 5/2, 9/2$). We calculate the Fermi liquid parameters by evaluating energies of eight independent particle-hole pair excitation configurations using a quantum Monte Carlo algorithm through correlated sampling. We used composite fermion many-body wave functions for 37 electrons on a toroidal geometry that are interacting through the Coulomb potential. We find F_2 to become increasingly negative as we go to higher Landau levels. This is consistent with experimental observations.

4:54PM T24.00013 Bulk-edge correspondence and entanglement spectra of quantum Hall trial wave functions, JEROME DUBAIL, NICHOLAS READ, Yale University, EDWARD REZAYI, California State University — We construct edge states wave functions for quantum Hall trial states built out of conformal blocks (e.g. Laughlin, Moore-Read or Read-Rezayi wave functions). We then compute the overlaps between these edge states in the thermodynamic limit. The result is that the Hilbert space of the edge theory is isomorphic to the one of the conformal field theory (CFT) which defines the quantum Hall state. This is a microscopic derivation of the bulk/edge correspondence for trial states given by conformal blocks. Our result definitely rules out the use of non-unitary theories for the construction of quantum Hall states. We obtain this result by analysing the quantum Hall droplet in the thermodynamic limit, under the assumption that all correlations are short-range inside the droplet. We argue that one is then left with a CFT in the domain outside the droplet, with a perturbed conformal boundary condition along the edge. We show that the entanglement spectra of these states can be tackled analytically with the same techniques.

5:06PM T24.00014 Finite-size studies of the $\nu = 5/2$ quantum Hall state in wide quantum wells: the effect of subband mixing and breaking of particle-hole symmetry¹, Z. PAPIĆ, F.D.M. HALDANE, Princeton University, E.H. REZAYI, California State University, Los Angeles — A number of theoretical studies have argued that the quantized plateau at half filling of the second Landau level is described by the Pfaffian wavefunction of Moore and Read, or by its particle-hole conjugate, the anti-Pfaffian. The two wavefunctions are difficult to compare in finite-size systems due to their different shifts in the spherical geometry, or because of their high mutual overlap on the torus. Here we propose a way to circumvent these problems by envisioning systems with periodic boundary conditions, for which the Pfaffian and anti-Pfaffian become orthogonal to each other due to their different symmetry properties under discrete rotations. Furthermore, we show that periodic boundary conditions can be used to study the Moore-Read ground state, as well as the collective excitation spectrum, in finite systems in a “quartered” Brillouin zone scheme. To demonstrate the utility of this method, we provide a realistic, two-component model of a wide quantum well that can unambiguously distinguish between the Pfaffian and anti-Pfaffian state in finite-sized systems. These results describe the recent experiments that probed the stability of the $\nu = 5/2$ state by tuning the mixing between electronic subbands and Landau levels in a wide quantum well.

5:18PM T24.00015 Quantitative analysis of the disorder broadening and the intrinsic gap for the $\nu=5/2$ fractional quantum Hall state, NODAR SAMKHARADZE, JOHN WATSON, GEOFF GARDNER, MICHAEL MANFRA, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University, GABOR CSATHY, Purdue University — We analyze several different methods of extracting intrinsic gaps of fractional quantum Hall states (FQHS) of the second Landau level from experimental data. Because of the discrepancy between these methods, we introduce a new way of estimating the disorder broadening in the second Landau level based on scaling of the gaps of the major odd denominator states. The results of our technique are in good agreement with a previously used method utilizing only the gaps of the even denominator states. We successfully apply this technique to several samples of high quality and find an excellent agreement between the estimated intrinsic gap and results of numerical simulations. We also report, for the first time, the dependence of the intrinsic gap of $\nu=5/2$ FQHS on Landau level mixing. This work was supported by the NSF grant DMR- 0907172.

5:30PM T24.00016 Quantum Topology of Lattice Dislocations in Fractional Chern Insulators, MAISSAM BARKESHLI, XIAOLIANG QI, Stanford University — An exciting prospect in condensed matter physics is the possibility of realizing fractional quantum Hall (FQH) states in simple lattice models without a large external magnetic field. Here we find a remarkable consequence of the interplay between the lattice translation symmetry and topological properties of these fractional Chern insulators. When the partially filled flat band has a Chern number N , it can be mapped to an N -layer quantum Hall system. We find that lattice dislocations can act as wormholes connecting the different layers and effectively change the topology of the space. Lattice dislocations become defects with non-trivial quantum dimension, topological degeneracy, and non-Abelian statistics, even when the FQH state being realized is a conventional Abelian FQH state.

Session T25 DCOMP DCMP: High Pressure: Theory 257A

2:30PM T25.00001 Nanoshells as a high-pressure gauge, JACQUES TEMPERE, NICK VAN DEN BROECK, KATRIJN PUTTENEERS, Universiteit Antwerpen, ISAAC SILVERA, Harvard University — Nanoshells, consisting of multiple spherical layers, have an extensive list of applications, usually performing the function of a probe. We add a new application to this list in the form of a high-pressure gauge in a Diamond Anvil Cell (DAC). In a DAC, where high pressures are reached by pressing two diamonds together, existing gauges fail at higher pressures because of calibration difficulties and obscuring effects in the diamonds. The nanoshell gauge does not face this issue since its optical spectrum can be engineered by altering the thickness of its layers. Furthermore their properties are measured by broad band optical transmission spectroscopy leading to a very large signal-to-noise ratio even in the multi-megabar pressure regime where ruby measurements become challenging. Theoretical calculations based on the Maxwell equations in a spherical geometry combined with the Vinet equation of state show that a three-layer geometry ($\text{SiO}_2\text{-Au-SiO}_2$) indeed has a measurable pressure-dependent optical response desirable for gauges.

2:42PM T25.00002 Pressure-induced phase transitions and superconductivity in platinum hydride¹, CHAO ZHANG, Beijing Computational Science Research Center, XIAOJIA CHEN, Department of Physics, South China University of Technology, HAIQING LIN, Beijing Computational Science Research Center — The transition metal hydrides have attracted much attention from the scientific community due to their promising properties from both fundamental and practical points of view. Here we present our recent work about platinum hydride under pressure. Structural phase transitions and superconducting properties of platinum hydride under pressure are explored through the first-principles calculations based on the density functional theory. Three new low-pressure phases (Pm-3m, Cmmm, and P4/nmm) are predicted, and all of them are metallic and stable relative to decomposed cases. Two high-pressure phases are close-packed structure with hydrogen atoms occupying the octahedral interstices. The superconducting critical temperature of two high-pressure phases correlates with the electron-phonon coupling. The presence of soft modes induced by Kohn anomalies and the hybridization between H and Pt atoms result in the strong electron-phonon coupling. Our results have great implications for other transition metal hydrides under pressure.

2:54PM T25.00003 ABSTRACT MOVED TO Y26.00015 —

3:06PM T25.00004 The hard-disk melting transition, ETIENNE BERNARD, Condensed Matter Theory, Massachusetts Institute of Technology, WERNER KRAUTH, Laboratoire de Physique Statistique, Ecole Normale Supérieure, France — Melting in two spatial dimensions, as realized in thin films or at interfaces, represents one of the most fascinating phase transitions in nature, but it remains poorly understood. Even for the fundamental hard-disk model, the melting mechanism has not been agreed upon after 50 years of studies. A recent Monte Carlo algorithm [1] allows us to thermalize systems large enough to access the thermodynamic regime. I will show that melting in hard disks proceeds in two steps with a liquid phase, a hexatic phase, and a solid. The hexatic-solid transition is continuous while, surprisingly, the liquid-hexatic transition is of first order [2]. This melting scenario solves one of the fundamental statistical-physics models, which is at the root of a large body of theoretical, computational, and experimental research. 1. Bernard, E. P.; Krauth, W. & Wilson, D. B. *Phys. Rev. E*, **2009**, 80, 056704 2. Bernard, E. P. & Krauth, W. *Phys. Rev. Lett.*, **2011**, 107, 155704

3:18PM T25.00005 Electric Field Induced Phase Transitions, MARCO NARDONE, Bowling Green State University, Bowling Green, Ohio, VICTOR KARPOV, University of Toledo, Toledo, Ohio — A novel theory of phase transitions that are driven by strong, symmetry-breaking electric fields is presented. The underlying mechanism is based on the formation of needle-shaped, metallic embryos that acquire strong dipole moments in the applied field. It is shown that the electrostatic contribution to the free energy can be so significant that it dominates the nucleation process and elongated metallic particles can form even in cases where they would be otherwise unstable in the bulk. As such, the theory predicts that any insulator will eventually form metallic inclusions when immersed in a sufficient electric field. Materials can thus be synthesized by the controlled application of a dc or laser field. In this work, the general mechanism is described and closed form expressions are presented for the field-dependent nucleation barrier and the effective field range as functions of material parameters. Overall, the theory presents a new parameter space to explore phase transitions and opens the venue of Field Induced Materials Synthesis (FIMS). As a provocative example, the potential for FIMS of metallic hydrogen at standard pressure is discussed; the effective field range is estimated to be $10^7 < E \ll 10^9$ V/cm (laser intensity $10^{12} < I \ll 10^{16}$ W/cm²).

3:30PM T25.00006 Consistent first-principles pressure scales for diffraction experiments under extreme conditions, ALBERTO OTERO-DE-LA-ROZA, School of Natural Sciences, University of California, Merced, 5200 North Lake Road, Merced, California 95343, USA, VICTOR LUNA CABAL, Departamento de Química Física y Analítica, Facultad de Química, Universidad de Oviedo, ES-33006 Oviedo, Spain — Diamond anvil cell (DAC) diffraction experiments are fundamental in geophysics and materials science to explore the behavior of solids under very high pressures and temperatures. A factor limiting the accuracy of DAC experiments is the lack of an accurate pressure scale for the calibration materials that extends to the ever-increasing pressure and temperature limits of the technique. In this communication, we address this problem by applying a newly developed technique that allows the calculation of accurate thermodynamic properties from first-principles calculations [Phys. Rev. B 84 (2011) 024109, 84 (2011) 184103]. Three elements are key in this method: i) the quasi-harmonic approximation (QHA) and the static energies and phonon frequencies obtained from an electronic structure calculation ii) the appropriate representation of the equation of state by using averages of strain polynomials and iii) the correction of the systematic errors caused by the exchange-correlation functional approximation. As a result, we propose accurate equations of state for typical pressure calibrants that can be used in the whole experimental range of pressures and temperatures. The internal consistency and the agreement with the ruby scale based on experimental data is examined.

3:42PM T25.00007 Low-temperature phases of dense hydrogen and deuterium by first-principles path-integral molecular dynamics, MARC TORRENT, GREGORY GENESTE, CEA, DAM, DIF, F-91297 Arpajon, France — The low-temperature phases of dense hydrogen and deuterium have been investigated using first-principles path-integral molecular dynamics, a technique that we have recently implemented in the ABINIT code and that allows to account for the quantum fluctuations of atomic nuclei. A massively parallelized scheme is applied to produce trajectories of several tens of thousands of steps using a 64-atom supercell and a Trotter number of 64. The so-called phases I, II and III are studied and compared to the structures proposed in the literature. The quantum fluctuations produce configurational disorder and are shown to systematically enhance the symmetry of the system: a continuous gain of symmetry in the angular density of probability of the molecules is found from classical particles to quantum D2 and finally to quantum H2. Particular emphasis is made on the “broken-symmetry” phase (phase II).

3:54PM T25.00008 Predictive equation of state method for heavy materials based on the Dirac equation and density functional theory, JOHN M. WILLIS, Los Alamos National Laboratory, ANN E. MATTSSON, Sandia National Laboratories — Density functional theory (DFT) provides a formally predictive base for equation of state properties. Available approximations to the exchange/correlation functional provide accurate predictions for many materials in the periodic table. For heavy materials however, DFT calculations, using available functionals, fail to provide quantitative predictions, and often fail to be even qualitative. This deficiency is due both to the lack of the appropriate confinement physics in the exchange/correlation functional and to approximations used to evaluate the underlying equations. In order to assess and develop accurate functionals, it is essential to eliminate all other sources of error. In this talk we describe an efficient first-principles electronic structure method based on the Dirac equation and compare the results obtained with this method with other methods generally used. Implications for high-pressure equation of state of relativistic materials are demonstrated in application to Ce and the light actinides. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:06PM T25.00009 Requirements for Predictive Density Functional Theory Methods for Heavy Materials Equation of State, ANN E. MATTSSON, Sandia National Laboratories, JOHN M. WILLIS, Los Alamos National Laboratory — The difficulties in experimentally determining the Equation of State of actinide and lanthanide materials has driven the development of many computational approaches with varying degree of empiricism and predictive power. While Density Functional Theory (DFT) based on the Schrödinger Equation (possibly with relativistic corrections including the scalar relativistic approach) combined with local and semi-local functionals has proven to be a successful and predictive approach for many materials, it is not giving enough accuracy, or even is a complete failure, for the actinides. To remedy this failure both an improved fundamental description based on the Dirac Equation (DE) and improved functionals are needed. Based on results obtained using the appropriate fundamental approach of DFT based on the DE we discuss the performance of available semi-local functionals, the requirements for improved functionals for actinide/lanthanide materials, and the similarities in how functionals behave in transition metal oxides. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:18PM T25.00010 ABSTRACT WITHDRAWN —

4:30PM T25.00011 High pressure/temperature equation of state of gold silver alloys¹, ZSOLT JENEI, MAGNUS J. LIPP, JAE-HYUN P. KLEPEIS, HYUNCHAE CYNN, WILLIAM J. EVANS, Lawrence Livermore National Laboratory, CHANGYONG PARK, HPCAT, Advanced Photon Source, Argonne National Laboratory — Gold-silver alloys crystallize in face centered cubic structures, like their constituent pure elements [McKeehan – Phys.Rev. 20, 424 (1922)]. The cell parameter of the alloys does not scale linearly with the ratio of Ag/Au. In this work we investigate the high-pressure/temperature behavior of gold-silver alloys with different Au/Ag ratios. Powder x-ray diffraction experiments performed at HPCAT/Advanced Photon Source confirm the stability of the alloy's fcc structure to pressures/temperatures exceeding 100 GPa/1000 K. We will present isothermal EOS of the alloys from ambient temperature up to 1000 K, discuss the thermal expansion and its variation with pressure.

¹This work performed under the auspices of the US DOE by LLNL under Contract DE-AC52-07NA27344. HPCAT use is supported by DOE-BES, DOE-NNSA, NSF, and the W.M. Keck Foundation. APS is supported by DOE-BES, under Contract No. DE-AC02-06CH11357.

4:42PM T25.00012 Persistence of Covalent Bonding in Liquid Silicon Probed by Inelastic X-ray Scattering, JUNPEI OKADA, Japan Aerospace Exploration Agency (ISAS/JAXA), P. SIT, Princeton U., Y.J. WANG, B. BARBIELLINI, Northeastern U., Y. WATANABE, U. Tokyo (JAPAN), A. BANSIL, Northeastern U., Y. SAKURAI, JASRI/SPRing-8 (JAPAN), M. ITOU, JASRI/SPRing-8, T. ISHIKAWA, ISAS/JAXA, K. KIMURA, U. Tokyo, P. PARADIS, ISAS/JAXA, S. NANAŌ, U. Tokyo — Metallic liquid silicon at 1787K is investigated using x-ray Compton scattering. An excellent agreement is found between the measurements and the corresponding Car-Parrinello molecular dynamics simulations. Our results show persistence of covalent bonding in liquid silicon and provide support for the occurrence of theoretically predicted liquid-liquid phase transition in supercooled liquid states. The population of covalent bond pairs in liquid silicon is estimated to be 17% via a maximally-localized Wannier function analysis. Compton scattering is shown to be a sensitive probe of bonding effects in the liquid state.

4:54PM T25.00013 Effects of the Structure of the Confinement Matrix on Liquid-Liquid Phase Transition and Density Anomaly, ELENA STREKALOVA, JIAYUAN LUO, GENE STANLEY, Boston University, GIAN-CARLO FRANZESE, Universitat de Barcelona, SERGEY BULDYREV, Yeshiva University — We investigate using molecular dynamics the effect of geometrical order in nanoconfinement of liquids with water-like anomalies that display liquid-liquid coexistence at low pressure and low temperature. Our studies using both a ramp and a shoulder interaction potentials show that regularly structured confinement matrices preserve the anomalies, while the phase diagram is shifted to lower temperatures, higher pressures and higher densities with respect to bulk. On the contrary, if the confinement matrices have no geometrical order, we find a drastically different phase diagram: the liquid-liquid coexistence region shrinks significantly and the anomalies are washed out. To understand this effect we calculate the changes in the system at the microscopic level. In the vicinity of the confining nanoparticles we observe that the liquid has a dramatic increase of density that we interpret as an entropic effect. We explain the macroscopic effect of confinement as a consequence of the amount of disorder that is introduced through the configuration of the confining nanoparticles.

5:06PM T25.00014 First-principles calculations for pressure-induced transition of Sr₂CuO₃, MITSURU KODERA, TAMIO OGUCHI, ISIR, Osaka University — One-dimensional cuprate, Sr₂CuO₃ has attracted much attention from the theoretical and material research. Recently, it is found that Sr₂CuO₃ exhibits the pressure-induced structural transition with the space group change. In this work, we perform the first-principles calculations in order to investigate the mechanism for the pressure-induced structural transition of Sr₂CuO₃. The calculation results are in good accordance with the experimental ones. The structural transition of Sr₂CuO₃ are related with the ionic interaction between strontium and oxygen atoms. We also discuss the electronic and magnetic structure of Sr₂CuO₃.

5:18PM T25.00015 Magnetic Phase Transition in Rare Earth Metal Holmium at Low Temperatures and High Pressures, SARAH THOMAS, WALTER UHOYA, LOWELL WENGER, YOGESH VOHRA, University of Alabama at Birmingham — The heavy rare earth metal Holmium has been studied under high pressures and low temperatures using a designer diamond anvil cell and neutron diffraction using a Paris-Edinburgh Cell at the Spallation Neutrons and Pressure (SNAP) Diffractometer. The electrical resistance measurement using designer diamond shows a change in slope at the Neel temperature as the temperature is lowered at high pressures. At atmospheric pressure TN=120 K and decreases with a slope of -4.7 K/GPa as pressure is increased, until reaching 9 GPa, at which pressure the magnetic ordering is lost. This correlates to the pressure at which there is a structural change from an hcp phase to an α -Sm structure. Neutron diffraction measurements made above and below the Neel temperature at increasing pressures show the reversibility of the change between the paramagnetic and antiferromagnetic states. The parameters of the low temperature incommensurate magnetic phase will be reported at various pressures.

Session T26 DCOMP: Focus Session: Computational Frontiers in Quantum Spin Systems II

257B

2:30PM T26.00001 Cubic Interactions and Quantum Criticality in Dimerized Antiferromagnets, S. WESSEL, RWTH Aachen University, Germany, L. FRITZ, Universitaet zu Koeln, Germany, R.L. DORETTO, Universidade Estadual Paulista, Brazil, S. WENZEL, EPFL, Switzerland, S. BURDIN, Universite de Bordeaux, France, M. VOJTA, TU Dresden, Germany — Dimerized quantum antiferromagnets can be driven through a quantum phase transition from a dimerized phase into a magnetically ordered state upon tuning the exchange parameters. In recent years, the critical properties in such dimerized antiferromagnets were examined in detail, based on large-scale quantum Monte Carlo simulations, which reported deviations from O(3) universality for specific two-dimensional geometries, in particular for the staggered-dimer antiferromagnet. Symmetry arguments and microscopic calculations exhibit that a nontrivial cubic term arises in the relevant order-parameter quantum field theory, related to three-particle interactions among the triplet excitations within the paramagnetic phase of this model. The consequences of such cubic terms are explored using a combination of analytical and numerical methods. Complemented by finite-temperature quantum Monte Carlo simulations, these results lead to the conclusion that critical exponents in dimerized antiferromagnets are identical to that of the standard O(3) universality class, but with anomalously large corrections to scaling for these specific dimerization geometries.

2:42PM T26.00002 Computational Studies of $T = 0$ Neel-Valence bond solid transitions in two dimensional quantum antiferromagnets, KEDAR DAMLE, Tata Institute, FABIEN ALET, SUMIRAN PUJARI, Univ. Paul Sabatier, Toulouse, ARGHA BANERJEE, Institute for Mathematical Sciences, India, ARUN PARAMAKANTI, University of Toronto — We use Quantum Monte Carlo techniques to study a direct quantum phase transition in two dimensional quantum antiferromagnets between a collinear Neel ordered state and a valence bond solid ordered singlet state. We contrast the strongly first order behavior of the transition in cases where the valence bond solid order is of a “staggered” type with the deconfined critical behavior seen in cases where the valence-bond solid order is of a columnar type. In the deconfined case, we find evidence for weak, apparently logarithmic violations of scaling. [References: preprint; Phys. Rev. B 83, 235111 (2011); Phys. Rev. B 83, 134419 (2011); Phys. Rev. B 82, 155139 (2010)]

2:54PM T26.00003 Velocities of Goldstone and critical modes in SU(2) symmetric quantum spin systems¹, ARNAB SEN, Max-Planck-Institute, Dresden, ANDERS SANDVIK, Boston University — The low-energy excitations of many interesting quantum spin systems are gapless and linearly dispersing. Examples include Goldstone modes in the Néel phase and critical modes at a $z=1$ quantum critical point. We calculate the velocities of such modes for a variety of SU(2) symmetric $S=1/2$ systems using quantum Monte Carlo (QMC) methods. We use two complementary approaches: a) The lowest triplet gap from the singlet ground state is calculated using $T=0$ projector QMC by measuring appropriate imaginary-time correlation functions. The velocity is obtained from extracted momentum dependent gaps. b) We use a method based on tuning the system to the cubic regime by varying its temperature to equate the variance of spatial and temporal winding numbers, which was recently used by Jiang [1] for a system with Goldstone modes. We find that this method can also be applied to a $z=1$ critical point (the critical point of an $S=1/2$ Heisenberg bilayer) and to the 1D Heisenberg spin chain, where there are no Goldstone modes. We also extract the velocity of the critical modes of the J-Q model. It agrees very well with the velocity obtained from a phenomenological approach [2] based on a spinon gas picture. [1] Jiang, Phys. Rev B 83, 024419 (2011) [2] Sandvik et al., Phys. Rev. Lett. 106, 207203 (2011)

3:06PM T26.00004 Unconventional versus conventional destruction of square lattice SU(N) magnetism¹, RIBHU KAUL, University of Kentucky — Recently we have found SU(N) symmetric square lattice spin models of quantum antiferromagnets, which have quantum phase transitions between magnetic and non-magnetic phases for arbitrary N , and which are nonetheless free of the “sign-problem” of quantum Monte Carlo. The absence of the notorious sign-problem allows detailed unbiased numerical simulations of two-dimensional magnetic quantum phase transitions on lattices containing in excess of 10^4 spins. Depending on the absence or presence of uncompensated Berry phases in our microscopic models we find evidence for both conventional first order phase transitions and unconventional continuous quantum phase transitions at which both Néel- and valence bond solid-order (VBS) are *simultaneously* quantum critical. A detailed quantitative study of the Néel and VBS scaling dimensions as a function of N provides compelling evidence that the long-wavelength description of these quantum critical points may be found in the CP^{N-1} gauge theory, as predicted by the deconfined quantum criticality scenario. R. K. Kaul and A. W. Sandvik, <http://arxiv.org/abs/1110.4130>. R. K. Kaul (forthcoming).

3:42PM T26.00005 Neel to valence-bond solid transitions in generalized amplitude-product states with correlated weights¹, YU-CHENG LIN, Graduate Institute of Applied Physics, National Chengchi University, Taiwan, JIE LOU, Institute for Solid State Physics, ISSP, University of Tokyo, Japan, YING TANG, ANDERS SANDVIK, Department of Physics, Boston University, USA — An amplitude-product state is a superposition of valence-bond states with the expansion coefficients being products of individual bond amplitudes that depend only on the bond shape. In two dimensions, these states have Neel order or are spin liquids, but they never have any valence-bond solid order. We construct generalized amplitude-product states on the square lattice which include correlated weights for short-range bonds. Using these states, we explore phase transitions between Neel phase, valence-bond solid phases, and spin liquid. We also study the Neel-VBS transition in the standard amplitude-product states in one dimension.

3:54PM T26.00006 Emergent U(1) Symmetry in Square Lattice Quantum Dimer Models, SYLVAIN CAPPONI, DAVID SCHWANDT, Laboratoire de Physique Théorique, CNRS & Université de Toulouse, F-31062 Toulouse, France, SERGEI ISAKOV, Institut für Theoretische Physik, ETH Zürich, CH-8093 Zürich, Switzerland, RODERICH MOESSNER, Max Planck Institut für komplexe Systeme, Nöthnitzer Straße 38, D-01187 Dresden, Germany, ANDREAS LÄUCHLI, Institut für Theoretische Physik, Universität Innsbruck, A-6020 Innsbruck, Austria — We report an exact diagonalization study of Rokhsar-Kivelson quantum dimer models on square lattice. Using a finite-size scaling analysis of excited energy levels, we are able to identify a regime of length scales where the quantum dimer model exhibits a $U(1)$ symmetry. Dimer order parameter histograms confirm this remarkable symmetry. Beyond this crossover length, columnar dimer order emerges at least for $v/t \lesssim 0.6$. Our interpretation is supplemented with field-theory analysis as well as large-scale quantum Monte-Carlo simulations.

4:06PM T26.00007 A round-trip from spin to quantum dimer models, MATTHIEU MAMBRINI, FABIEN ALET, CNRS, Université de Toulouse, F-31062 France, SYLVAIN CAPPONI, Université de Toulouse, F-31062 France — Short-range valence bonds wave-functions are often used as a paradigm for non-magnetic states (such as spin liquids or valence bond crystals). Recently, two local $S=1/2$ spin Hamiltonians which admits nearest neighbor valence bond wave-function(s) as ground-state(s) on the square lattice have been proposed by Cano and Fendley [Phys. Rev. Lett. **105**, 067205 (2010)]. We present a numerical study, by means of exact diagonalizations and diagonalizations restricted in the subspace spanned by nearest neighbor valence bond states, of the ground state and excitations of these models. We show that it corresponds to a new type of spin liquid state, with gapped spin but gapless non-magnetic excitations. Mixing the two models is shown to stabilize valence bond crystal ground states that are very reminiscent of the phases present in the Rokhsar-Kivelson quantum dimer model phase diagram. Using a generic mapping scheme [Phys. Rev. B **81**, 214413 (2010)] of spin hamiltonians to generalized quantum dimer models we show how this correspondence between the phase diagram of a local $S=1/2$ spin hamiltonian and the Rokhsar-Kivelson quantum dimer model can be understood.

4:18PM T26.00008 Phase Diagram of a Frustrated Quantum Antiferromagnet on the Honeycomb Lattice: Magnetic Order versus Valence-Bond Crystal Formation, DAVID SCHWANDT, FABRICIO ALBUQUERQUE, Laboratoire de Physique Théorique, Université de Toulouse, UPS (IRSAMC), CNRS, F-31062 Toulouse, France, BALAZS HETÉNYI, Department of Physics, Bilkent University, Ankara, Turkey, SYLVAIN CAPPONI, MATTHIEU MAMBRINI, Laboratoire de Physique Théorique, Université de Toulouse, UPS (IRSAMC), CNRS, F-31062 Toulouse, France, ANDREAS LÄUCHLI, Institut für Theoretische Physik, Universität Innsbruck, A-6020 Innsbruck, Austria — We present a comprehensive computational study of the phase diagram of the frustrated $S = 1/2$ Heisenberg antiferromagnet on the honeycomb lattice, with second-nearest (J_2) and third-neighbor (J_3) couplings. Using a combination of exact diagonalizations of the original spin model, of the Hamiltonian projected into the nearest neighbor short range valence bond basis, and of an effective quantum dimer model, we determine the boundaries of several magnetically ordered phases in the region $J_2, J_3 \in [0, 1]$, and find a sizable magnetically disordered region in between. We characterize part of this magnetically disordered phase as a *plaquette* valence bond crystal phase.

4:30PM T26.00009 Plaquette order and deconfined quantum critical point in the spin-1 bilinear-biquadratic Heisenberg model on the honeycomb lattice¹, HUI-HAI ZHAO, Institute of Physics, Chinese Academy of Sciences, Beijing, CENKE XU, Department of Physics, University of California, Santa Barbara, Q.N. CHEN, Institute of Theoretical Physics, Chinese Academy of Sciences, Beijing, Z.C. WEI, M.P. QIN, Institute of Physics, Chinese Academy of Sciences, Beijing, G.M. ZHANG, State Key Laboratory of Low-Dimensional Quantum Physics and Department of Physics, Tsinghua University, Beijing, T. XIANG, Institute of Physics and Institute of Theoretical Physics, Chinese Academy of Sciences, Beijing — We have precisely determined the ground state phase diagram of the quantum spin-1 bilinear-biquadratic Heisenberg model on the honeycomb lattice using the tensor renormalization group method. We find that the ferromagnetic, ferroquadrupolar, and a large part of the antiferromagnetic phases are stable against quantum fluctuations. However, around the phase where the ground state is antiferro-quadrupolar ordered in the classical limit, quantum fluctuations suppress completely all magnetic orders, leading to a plaquette order phase which breaks the lattice symmetry but preserves the spin $SU(2)$ symmetry. The quantum phase transition between the antiferromagnetic phase and the plaquette phase is found to be a direct second order transition, being the first candidate of the deconfined quantum critical point for the spin-1 quantum systems.

4:42PM T26.00010 Three-sublattice order in the $SU(3)$ Heisenberg model on the square and triangular lattice, BELA BAUER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland and Station Q, Microsoft Research, Santa Barbara, CA 93106, PHILIPPE CORBOZ, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland and Institut de theorie des phenomenes physiques, Ecole Polytechnique Federale de Lausanne, ANDREAS M. LAEUCHLI, Institut fuer Theoretische Physik, Universitaet Innsbruck, Austria and Max-Planck-Institut fuer Physik komplexer Systeme, Dresden, Germany, LAURA MESSIO, Institut de theorie des phenomenes physiques, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland, KARLO PENC, Research Institute for Solid State Physics and Optics, H-1525 Budapest, P.O. Box 49, Hungary, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, 8093 Zurich, Switzerland, FREDERIC MILA, Institut de theorie des phenomenes physiques, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland — We present a numerical study of the $SU(3)$ Heisenberg model on the triangular and square lattice by means of the density-matrix renormalization group (DMRG) and infinite projected entangled-pair states (iPEPS). For the triangular lattice we confirm that the ground state has a three-sublattice order with a finite ordered moment which is compatible with the result from linear flavor wave theory (LFWT). The same type of order has recently been predicted also for the square lattice. However, for this case the ordered moment cannot be computed with LFWT due to divergent fluctuations. Our numerical study clearly supports this three-sublattice order, with an ordered moment of $m=0.2-0.4$ in the thermodynamic limit.

4:54PM T26.00011 Zero- vs. finite-field transition in $S=1$ Heisenberg antiferromagnet with single-ion anisotropy, PINAKI SENGUPTA, IAN YAP, ZHIFENG ZHANG, Nanyang Technological University, Singapore — We use large scale quantum Monte Carlo simulation on finite size lattices to study the ground state and finite temperature transitions in a $S = 1$ Heisenberg antiferromagnet (HAFM) with single-ion anisotropy (D) in the presence of an external magnetic field (h_z). The ground state phase diagram (in the $h_z - D$ plane) is characterized by a quantum paramagnetic phase (QPM) at large D and small h_z and an XY-AFM phase at small D and/or large h_z separated by a continuous transition. We show that the QPM to XY-AFM transition belongs to the XY universality class at $h_z = 0$ (driven by varying D) whereas it belongs to the BEC universality class at $h_z \neq 0$ (driven by either varying D at constant h_z or varying h_z at constant D). This has important implication in the behavior of the specific heat at the transition point which can be verified experimentally. Finally, we discuss the experimental relevance of our results in the case of DTN.

5:06PM T26.00012 Ferronematic order in a spin-1 Heisenberg antiferromagnet, KEOLA WIERSCHEM, PINAKI SENGUPTA, Nanyang Technological University, Singapore, CRISTIAN BATISTA, Theoretical Division, Los Alamos National Lab — We study the field-induced ground-state phase transition of a spin-1 Heisenberg antiferromagnet with large easy-axis single-ion anisotropy D . Direct spin-wave treatment predicts a single first-order phase transition from an antiferromagnetic Néel phase at low magnetic fields to a fully polarized state at high magnetic fields. Mean field arguments, based on an effective spin-1/2 model that is exact in the $D \rightarrow \infty$ limit, show that this transition is preempted by an intermediate phase with double-spin-flip correlations. We call this phase the *ferronematic* phase, as the effective spin model for large (negative) D is a spin-1/2 XXZ model with *ferromagnetic* transverse exchange. Using exact diagonalization and quantum Monte Carlo, we confirm the presence of the ferronematic phase. Long range order is observed in the equal-time Green's function $\langle S_i^+ S_i^+ S_j^- S_j^- + H.c. \rangle$, which is the correlation function for ferronematic order. We also show the rapid convergence to the effective model for large values of D .

5:18PM T26.00013 Monte Carlo study of a $U(1) \times U(1)$ system with π -statistical interaction, SCOTT GERAEDTS, OLEXEI MOTRUNICH, California Institute of Technology — We study a $U(1) \times U(1)$ system with two species of loops with mutual π -statistics in (2+1) dimensions. We are able to reformulate the model in a way that can be studied by Monte Carlo and we determine the phase diagram. In addition to a phase with no loops, we find two phases with only one species of loop proliferated. The model has a self-dual line, a segment of which separates these two phases. Everywhere on the segment, we find the transition to be first-order, signifying that the two loop systems behave as immiscible fluids when they are both trying to condense. Moving further along the self-dual line, we find a phase where both loops proliferate, but they are only of even strength, and therefore avoid the statistical interactions. We study another model which does not have this phase, and also find first-order behavior on the self-dual segment.

2:30PM T28.00001 Interaction-driven versus disorder-driven transport in ultra-dilute GaAs two-dimensional hole systems¹, JIAN HUANG, Wayne State University, L.N. PFEIFFER, K.W. WEST, Princeton University — It is well-known that the insulating behavior in the two-dimensional metal-to-insulator transition demonstrates a finite temperature conduction via hopping. Recently, however, some very strongly interacting higher purity two-dimensional electron systems at temperatures $T \rightarrow 0$ demonstrate certain nonactivated insulating behaviors that are absent in more disordered systems. Through measuring in dark the T -dependence of the conductivity of ultra-high quality 2D holes with charge densities down to $7 \times 10^8 \text{ cm}^{-2}$, an approximate power-law behavior is identified. Moreover, for the lowest charge densities, the exponent exhibits a linearly decreasing density-dependence which suggests an interaction-driven nature. Such an electron state is fragile to even a slight increase of disorder which causes a crossover from nonactivated to activated conduction. The non-activated conduction may well be an universal interaction-driven signature of an electron state of strongly correlated (semiquantum) liquid.

2:42PM T28.00002 Abruptness improvement of the interfaces of AlGa_N/Ga_N superlattice by cancelling asymmetric diffusion, DUANJUN CAI, XIAOHONG CHEN, NA LIN, FUCHUN XU, HANGYANG CHEN, Department of Physics, Xiamen University, Xiamen, 361005, China, SHANSHAN CHEN, University of Texas at Austin — Interface abruptness has been an important issue in the construction of quantum wells as active layer in optoelectronic devices, which is extremely crucial in achieving stronger quantum confinement and consequently higher emission efficiency. The interfacial sharpness is highly associated with the crystal structure as well as the elemental transition. However, few studies have been done focusing on the elemental diffusion effect at the interface. In this work, the accurate determination was approached to the elemental inter-diffusion depth across the Ga_N/Al_{0.5}Ga_{0.5}N interfaces by using transmission electron microscopy, Auger electron microscopy, and X-ray diffraction. The Ga_N/Al_{0.5}Ga_{0.5}N superlattice was grown by metalorganic chemical vapor deposition (MOCVD) at high growth temperature (1070 °C). The results showed that the Al diffusion at the upper and lower interfaces of Al_{0.5}Ga_{0.5}N barrier appears an asymmetric behavior, which is 0.62 and 0.99 nm, respectively. Such will lead to the gradient interfacial region and asymmetric quantum well, affecting the carrier quantum confinement. To improve the abruptness of the interface and to modify the asymmetric diffusion, self-compensation pair technique was proposed and introduced to the growth of the lower Al_{0.5}Ga_{0.5}N/Ga_N interface, blocking the Al downward diffusion. First-principles simulations also showed that the structural relaxation at the strained heterointerface influences the electronic structure as well as elemental diffusion.

2:54PM T28.00003 Local Structure of Amorphous GaN_{As} Alloys Across the Composition Range, ALEJANDRO LEVANDER, University of California, Berkeley, KIN YU, Lawrence Berkeley National Laboratory, SERGEI NOVIKOV, University of Nottingham, ZUZANNA LILIENTAL-WEBER, Lawrence Berkeley National Laboratory, OSCAR DUBON, University of California, Berkeley, TOM FOXON, University of Nottingham, JUNQIAO WU, University of California, Berkeley, WLADEK WALUKIEWICZ, Lawrence Berkeley National Laboratory — Typically only dilute (up to ~10%) highly mismatched alloys (HMAs) can be grown due to the large differences in atomic size and electronegativity of the host and the alloying elements. Recently, we overcame the miscibility gap of the Ga_{N_{1-x}As_x} system using low temperature molecular beam epitaxy (LT-MBE) and successfully synthesized alloys over a wide composition range. In the intermediate composition range ($0.10 < x < 0.75$) the resulting alloys are amorphous. To gain a better understanding of the amorphous structure, the local environment of the As and Ga atoms was investigated using extended x-ray absorption fine structure (EXAFS). The EXAFS analysis shows a high concentration of dangling bonds compared to the crystalline binary endpoint compounds of the alloy system. The disorder parameter was larger for amorphous films compared to crystalline references, but comparable with other amorphous semiconductors. By examining the Ga local environment, the dangling bond density and disorder associated with As-related and N-related bonds could be decoupled. The N-related bonds had a lower dangling bond density and lower disorder. The significant dangling bond density may help explain the difficulty of doping the material.

3:06PM T28.00004 Characterization of GaN grown on Si substrate with sputtering AlN buffer layer by molecular beam epitaxy¹, WEN-YUAN PANG, IKAI LO, Y.C. HSU, C.H. SHIH, C.H. HU, Y.C. WANG, Department of Physics, National Sun Yat-sen University, Kaohsiung, Taiwan, SEAN WU, Department of Electrical Engineering, Far East College, Tainan, Taiwan — This study reports the characterization of GaN grown on Si substrate with sputtering AlN buffer layer by plasma-assisted molecular beam epitaxy. Structural properties were measured by X-ray diffraction measurement and transmission electron microscopy. XRD spectrum showed the sputtering buffer layer which was mainly (100)_{AlN} and followed by the GaN epilayer which contained poly M-plane GaN and other structural planes such as (002)_{GaN} (c-plane), and (101)_{GaN}. In TEM analysis, we demonstrated GaN of c- and A-plane grains. The pure M-plane GaN was also found in the form of grain and the high-resolution images showed clear atomic arrangement. Besides, the diffraction pattern with multi M-plane GaN was attributed to several M-plane GaN crystals which were grown in different orientations on in-plane surface. In addition, optical properties measured by photoluminescence and cathodoluminescence measurement both showed two main peaks at 3.2 eV and 3.4 eV, indicated that zinc-blende and wurtzite structure exist in the GaN layer at the same time.

3:18PM T28.00005 Characterization of InGa_N/Ga_N Quantum Well grown on Ga_N microdisk using γ -LiAlO₂ substrate by Plasma-assisted Molecular Beam Epitaxy¹, YU-CHI HSU, IKAI LO, W. Y. PANG, C.H. SHIH, C.H. HU, Y.C. WANG, C.C. YANG, Y.C. LIN, S.T. YOU, Department of Physics, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan, MITCH M.C. CHOU, Department of Materials and Optoelectronic Science, National Sun Yat-Sen University, Kaohsiung 80424, Taiwan — The InGa_N/Ga_N quantum wells grown on Ga_N microdisks by plasma-assisted molecular beam epitaxy (PAMBE) have been investigated. The optical properties and micro-structure of InGa_N/Ga_N quantum wells were studied by Cathodoluminescence (CL) and transmission electron microscope (TEM). According to the observation of high-resolution TEM, we obtained the high quality of InGa_N/Ga_N quantum wells grown on Ga_N micro-disk. The In-ratio (x) of In_xGa_{1-x}N is ~8% determined by the measurement of energy-dispersive X-ray spectroscopy (EDX). The optical gap of In_{0.08}Ga_{0.92}N was measured to be ~3eV determined by CL measurement, which is consistent with the calculation of bowing parameters and the measurement of EDX.

3:30PM T28.00006 Unraveling the Atomic Structure of GaN(0001) Pseudo-1×1: Surface-Electron-Gas Mediated Dimer Ordering¹, TIANJIAO CHEN, Ohio University Nanoscale and Quantum Phenomena Institute, NOBORU TAKEUCHI, Centro de Nanociencias y Nanotecnología, Universidad Nacional Autónoma de México, KANGKANG WANG, DANDA ARCHAYA, YINGHAO LIU, SAW-WAI HLA, ARTHUR SMITH, Ohio University Nanoscale and Quantum Phenomena Institute — Gallium nitride based light emitting devices have seen a steep rise of attention in recent years because of their potential in revolutionizing the current lighting industry. Of great importance in advancing the material technology is the understanding of the GaN(0001) surface, onto which most of the commercial devices are grown. We report a novel dimer-based model for Ga-rich GaN(0001), which exhibits an intriguing reconstruction known as the pseudo-1×1. To unravel its atomic structure, we have cooled the surface to cryogenic temperatures while monitoring the reconstruction by reflection high-energy electron diffraction and scanning tunneling microscopy. Upon cooling, the pseudo-1×1 phase transforms into a new phase consisting of buckled Ga-dimers on the surface. This observation then strongly suggests the existence of Ga dimers also at the room-temperature surface, although only partially ordered compared to the low temperature case. Combined with first-principles calculations, we propose a new model for the pseudo-1×1 consisting of dimers that are spaced ~1.9 nm (6a) apart along <1120> azimuths, while being randomly distributed along other directions. The mechanism of this partial ordering is identified to be through the surface electron gas residing within the bulk band-gap.
